

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

NO. CXXVIII.

PLATE I.

MR. CLARE SEWELL READ,

ONE OF THE MEMBERS FOR EAST NORFOLK.

THE FARMER MEMBER—a title which he has so honourably earned for himself—is a farmer born and bred. He is a native, moreover, of the county which he represents, with Ketteringham as the place of his birth, and 1826 as the year. He was, too, home-educated at the ordinary commercial schools until the 15th year of his age, when he went into the study of agriculture under his father, who was then farming some 1,300 acres of land. With five years' experience in this way, Mr. Sewell Read considered himself sufficiently well grounded to undertake the management of a large farm in Pembrokeshire, on the Orielson property, and held on lease by Colonel, now Sir Hugh Owen, and Mr. Herbert Kinderley. He continued here until 1850, when he accepted the appointment of agent and steward to Lord Macclesfield on the Oxfordshire estates around Shirburn Castle. After four years more thus occupied Mr. Read returned to Norfolk, and "set up for himself" at Barton Bendish, where, however, he only remained for two years. In 1857 he changed farms with his father, and entered upon the Plumstead House occupation, which in turn he gave up at Michaelmas, 1865, and removed to Honingham Thorpe, where he holds a farm under Lady Bayning. Mr. Read, senior, died as a tenant of Sir Hanson Berney at Barton Bendish.

From his very outset in life, Mr. Sewell Read had distinguished himself as a young man of much practical ability and proportionate promise. During his brief residence in Pembrokeshire he wrote the prize essay on the farming of South Wales for the

*Journal of the Royal Agricultural Society*; and, with his hand once in, he followed this up with two more prize reports, while at Shirburn, on the farming of Oxfordshire and of Buckinghamshire. A year or two after his return, he supplied by special request to the *Royal Journal* an article on the recent improvements in Norfolk farming, which serves as a kind of appendix or continuation of Bacon's elaborate essay, written some fifteen years previously. Mr. Sewell Read's career may consequently be followed by these papers, which it is scarcely necessary to say are amongst the most valuable contributions to the Society's *Journal*. But Mr. Read has been before the public in other ways. So far back as 1848, when only just of age, he acted as a judge at a meeting of the Pembrokeshire Farmers' Club, and again at the show of the Carmarthenshire Agricultural Society in the year following. In his own county he has also been in office, chiefly, if we remember aright, over the polled milking stock; but it is as a judge of implements at some of the more severe trials of the Royal Agricultural Society that Mr. Sewell Read's authority has been established. No more conscientious man ever accepted office, and none ever worked harder in the performance of his duties. He was in this way a man after Mr. Fisher Hobbs' own heart, and often would the steward speak to the pluck with which the young judge stuck to his work. Mr. Read first came out at Carlisle in 1854, and, beyond his labours in the field or the yard, he was mainly instrumental in preparing the reports. He has, indeed, been at times very ready with his pen

through other channels—such as the *Mark Lane Express* and the Norfolk papers; while beyond his own proper business as a farmer he has had some considerable experience as a valuer and land-agent, having previous to his election been extensively employed in his own county and other parts of England.

With such a character to go on, no wonder when at the election in 1865 the farmers of Norfolk resolved to have a man of their own to represent them, they looked naturally enough to Mr. Sewell Read; but he was very loath to come forward, and his nomination was only determined upon at the very last moment. Nevertheless he was returned, free of expense, by a majority of a thousand votes over a brother of the Lord-Lieutenant and a son of the famous Mr. Coke of Holkham. "The Repeal of the Malt-tax" and "A Farmer for Farmers" were the rallying cries of his committee, with whom party politics did not go for much; nevertheless, Mr. Read was supported by the great body of the Conservatives, backed by a few Independents. On the hustings he announced himself as a Liberal-Conservative, explicitly stating his belief that "more extensive and beneficial reforms would be passed by the Conservatives than would ever be obtained from a Whig Government," characterizing the latter, then in office, as "such sleepy Tories in power, and such thundering Radicals in Opposition." During the time he has been in Parliament he has pretty generally followed up this declaration, as he may be considered a supporter of the Ministry, although he has never hesitated to declare against them, either in or out of the House, when he has thought they have been neglecting the claims of the agricultural interest, or making a mere stalking-horse of the farmer to serve their own purposes.

Mr. Sewell Read, in fact—as he himself has said, on the same showing as the Noble Lord who sits for Arundel because he happens to be a Roman Catholic represents two millions—may be supposed to represent all the tenant-farmers. And never was such a responsibility more bravely borne, as never has there been a greater success. From all quarters and by all sides alike is Mr. Sewell Read's position "as one having authority" recognised. Mr. Gladstone on one occasion went almost out of his way to speak to the merits of the honourable member for East Norfolk, as "one whose modesty was only equalled by the ability which he displayed, and the knowledge he manifested of every subject he took in hand."

Mr. Sewell Read's name is not continually to be found as figuring in the debates, but he never speaks without commanding attention, and is never absent when the interests of his large body of constituents call on him to be present. There is a simplicity in his manner, a want of anything like straining after effect, that is of itself effective; while his bearing, as free from pretension as from any mock humility, carries with it all the weight of self-respect and true dignity. An honourable gentleman, who possibly like Mr. Read, found himself somewhat to his surprise in the House of Commons, complained to his friends, after an experience of two or three years, that he never had anything to do, and had never been put upon a Committee. Mr. Read's complaint would, we fancy, be rather in the other direction, and we have had some opportunity of seeing how hard he works. Of course, he is on every committee at all connected with his own pursuits—the Malt-Tax, the Foreign Cattle Market, the County Finance, and so forth; as he was very early called to act upon an Election Committee, was one of the most active of the Cattle-Plague Commissioners, and has had daily to encounter a correspondence the extent of which may be imagined now that the farmers of England are taking to political life with only one man to represent them. Let us just say further that beyond his Parliamentary duties and their "contingences" Mr. Sewell Read is at this moment the chairman of the Farmers' Club, the vice-president of the Chamber of Agriculture, a member of the Council of the Royal Agricultural Society of England, a member of the Council of the Smithfield Club, president of the Norfolk Chamber of Agriculture, chairman of the Norfolk Cattle Plague Association, with no doubt an &c. &c. that is accumulating almost as rapidly as the nails in the famous horse-shoe problem.

It is a delicate topic to touch on, but one so creditable to all concerned, that we shall venture to do so—Mr. Sewell Read's committee proposed not only to pay all the election, but also their member's Parliamentary expenses. This offer was respectfully declined, but a considerable sum remains in hand towards defraying the cost of the coming election. There should be, we trust, no doubt as to the result of this, as scarcely anything more untoward could occur to the cause than that in the Senate the services of Mr. Sewell Read should be lost to agriculture.

## PLATE II.

## ON THE FLAGS.

Perhaps the best joke of all at that Islington Exhibition happened just when the hubbub was at its highest—when the bell was tolling, the people hurrahing or hooting, the horses refusing, and the Judges and other authorities getting in each other's way. Just then, two or three distinguished, but much perplexed foreigners were also discovered within the magic circle—gentlemen who, it appeared, had been sent over “special” to see for themselves how such a show should be conducted. If they can but carry back with them the notion in its entirety, surely all Paris will go into ecstasies over the tuneful gongs, the give-and-take jumps, the “get-ready” telegrams, and the wild rushes of the riders. Such a scene must have been “made” for a Frenchman!

And we alas! have seen Yarm and Middlesboro', and Guisbro', and Redcar, where the horse and the hound show lacked all this mosaic setting, and yet what delightful days those were! It was a study, and a quiet study too, to watch men like Mr. Williamson, Mr. Milbank, Captain Percy Williams, and Sir John judge hounds, with the crack huntsmen of England, headed by Tom Sebright and Treadwell, judging the Judges, as they brought out a couple of promising puppies, or

Ben Morgan 'ticed the old bitch to straighten herself before them. And then some one would draw out his tape, while a friend from the side would greet him

“With line and rule works many a—swell;  
Good morning, sir!”

“Three hours on the flags,” says Mr. Vyner, “may be very agreeably spent by a real sportsman, but it is a sad bore to one who is not an admirer of the symmetrical.” Our own impression, however, is that the Yorkshire Hound Shows, under the conduct of a sportsman like Mr. Parrington, have tended more than anything else to make men admirers of the symmetrical; or, in other words, to take a real interest in hounds. There will be the now annual show in the first week in August at Wetherby; to be held in association with the Yorkshire Agricultural Society, but no longer on the same ground, as it was found that the hounds were, if anything, rather too attractive a feature, so that, what with horses and hounds, the implement makers more especially were left in the cool shade. For our own part, we have long continued to urge the adoption of the present arrangement as the more preferable.

## GREEN MANURE.

BY CUTHBERT W. JOHNSON, F.R.S.

Green manure was almost the first used of fertilizers. As soon as man began to till the earth he turned into the soil the plants with which it was tenanted. It was only when by successive crops he had impoverished the land, that it became necessary to find some additional means for restoring its fertility. Some of Dame Nature's hints would soon lead to the employment of green crops as a manure. The gradual formation of beds of peat, in the hollows of even the most barren soils, would naturally suggest to the early cultivator that certain plants had the power of deriving almost all their support from the atmosphere and from water; it would then become a question as to which of these were the best able to thus rapidly supply themselves with that requisite nourishment.

Now, the earliest of agricultural writers, whose works have escaped to us, allude to the cultivation, as a green manure, by the Italian farmers, of the lupine. This plant grows well even on exhausted soils, and, when in

flower, is still ploughed into the soil by the farmers of Italy as a green fertilizer. For the same purpose the farmers of some districts of England cultivate the buckwheat, a plant which will grow on impoverished soils; in other districts they plough-in a crop of coleseed, which, like the lupine and the buckwheat, derives a more than an ordinary supply of its nourishment from the atmosphere. On almost all the sea coasts of our islands the green sea-weeds are eagerly collected by the farmers, and employed as a manure; and in some districts the leaves of our root crops are as carefully and as beneficially ploughed into the soil; we also learn from Liebig that in Germany the best results have been obtained from manuring the vineyards with the outtings of the vine. “The branches are cut from the vine in July or August, whilst still fresh and moist. If they are then cut into small pieces and mixed with the earth, they undergo putrefaction so completely, that, as I have learned by experience, at the end of four weeks not the smallest trace of them can be

found. Some cut them in small pieces and hoe them into the soil." (*Organic Chem.* 213.)

Still, we are all aware that green manures have never been generally or systematically used; for, as I have on another occasion remarked, the agriculturist has ever been more desirous of employing as food for his stock the vegetable produce of his land, than to bury it in the earth to promote the future productiveness of the soil. Yet whenever green succulent substances, such as weeds, river collections, sea-weed, &c., have been used, the result has almost always been satisfactory. The putrefaction of the vegetables, and the gases in that case emitted, appear to be on all occasions highly invigorating and nourishing to the succeeding crop. During this operation the presence of water is essentially necessary, and is most probably decomposed. The gases produced vary in different plants—those which contain gluten emit ammonia; onions, and a few others, evolve phosphuretted hydrogen; carbonic acid gas and hydrogen gas, with various vegetable matters, are almost always abundantly formed. All these gases, when mixed with the soil, must be very nourishing to the plants growing upon it. The observations of the farmer assure us that they are so. He tells us that all green manures cannot be employed in too fresh a state; that the best corn is grown where the richest turf has preceded it; and that where there is a good produce of red clover, there will assuredly follow an excellent crop of wheat; he finds, also, when he ploughs in his crop of buckwheat to enrich his land, that this is most advantageously done when the plant is coming into flower. The chemical explanation of these practical observations is not difficult. "All green succulent plants," said Davy, "contain saccharine or mucilaginous matter, with woody fibre, and readily ferment; they cannot, therefore, if intended for manure, be used too soon after their death. When green crops are to be employed for enriching a soil, they should be ploughed in, if it be possible, when in flower, or at the time the flower is beginning to appear; for it is at that period that they contain the largest quantity of easily-soluble substances, and that their leaves are most active in forming nutritive matter. Green crops, pond weeds, the parings of hedges or ditches, or any kind of fresh vegetable matter, require no preparation to fit them for manure. The decomposition slowly proceeds beneath the soil, the soluble matters are gradually dissolved, and the slight fermentation that goes on, checked by the want of a free communication of air, tends to render the woody fibre soluble, without occasioning the rapid dissipation of elastic matter. When old pastures are broken up and made arable, not only has the soil been enriched by the death and slow decay of the plants which have left soluble matters in the soil, but the roots and leaves of the grasses living at the time, and occupying so large a part of the surface, afford saccharine, mucilaginous, and extractive matters, which become immediately the food of the crop, and the gradual decomposition affords a supply for successive years" (*Agricultural Chemistry*, p. 280).

But the question still remains to be more clearly answered, How do certain plants, instead of impoverishing the soil on which they grow, add, if ploughed into it, carbonaceous matters? Now, to this point Professor Voelcker has not long since directed his attention. He tells us (*Journ. Roy. Ag. Soc.*, vol. xxv., p. 532) that "we have abundant proof that it is chiefly the carbonic acid of the atmosphere that supplies the carbon of plants, or, in other words, the great bulk of all vegetation. It is calculated, indeed, that at least three-fourths of the dry substance of plants is derived from the carbonic acid of the atmosphere. During the day-time the absorption takes place continuously; and no sooner have the leaves absorbed carbonic acid than they set about the work of de-

stroying its form, assimilating the carbon, manufacturing it into starch, gum, sugar, and other combinations found in all vegetable productions, and at the same time throwing off the oxygen, so as to restore the balance."

"And," continues the Professor, in another portion of his valuable Essay, "the observations I have hitherto made all tend to show the direct influence which the atmosphere has in the nutrition of plants; but there is another part which it plays in the growth of vegetables, which, though it may be called the indirect one, is so great in its effect, that we may say positively that all soils which are not penetrated by air are unproductive, no matter how much food they may otherwise contain. Cases are constantly brought under my notice, of soils, sent for examination, which are characterised as unproductive, but turn out to contain an abundance of all the mineral constituents required for the growth of plants, and require only to be thoroughly penetrated by the air in order to furnish an unlimited quantity of food. The atmosphere really exercises a most beneficial effect both on the inorganic and organic constituents of the soil. I have alluded to the large quantity of carbonic acid present in the air which exists in the interstices of the soil, but this supply cannot be produced unless the air finds its way into the soil. An excess of organic matter in the shape of decaying roots or leaves is so injurious, that where it exists in soils which are not easily penetrated by air it would be much better for it to be burnt altogether away. At first sight this may appear to involve a great waste of useful material in clay soils; but if the beneficial effect be greater than the sacrifice, it can scarcely be called a waste; for although serious doubt has been entertained respecting the utility of burning, some soils are with so much difficulty penetrated by air, that burning is the only way of destroying the organic matter, which when present in an imperfectly aerated condition is rank poison to most cultivated plants. It is certain that the destruction of sour humus, as it has been called—though in a chemical point of view all humus is acid—has been attended with most beneficial effects, and when recourse cannot be had to proper means of aëration, this destruction has been practised with great advantage to the succeeding crop, even if, as in the case of turnips, it would be otherwise benefited by the presence of carbonaceous matters in the soil. When, however, we can effect the destruction of organic matters by the atmospheric oxygen, the practical result, I have no doubt, will be greater; for not only does the air, and more especially the atmospheric oxygen, act upon the organic matters in producing carbonic acid, but it also has an important effect upon them in producing nitrates in the soil.

"We see then that it is not only from the atmosphere by their leaves, but from the soil by their roots that plants derive their supplies of carbonic acid gas. Some time since, M. Boussingault made some very careful experiments upon the amount of carbonic acid which occurred in soils, and he found that whilst the atmosphere that rested upon the soil only gave four to five in every 10,000 parts, the air in the soil contained, in sandy soil recently manured, 217 parts of carbonic acid in every 10,000 parts. Shortly after rain, the air from the same soil was again analyzed, and was found to contain as much as 974 parts of carbonic acid; evidently showing that the wetting of organic matter, and the rapid decomposition which through contact with the porous earth had taken place in organic matter had led to the destruction of the humus, and the formation of large quantities of carbonic acid. This threw some light upon the very startling growths sometimes noticed, especially with regard to root crops. They knew how very rapidly young turnips started after a good shower of rain, if the land had been

well dunged, arising from the rapid production of carbonic acid in the soil. They looked in vain for this result in soils which had not been properly cultivated. The quantity of organic nitrogen in the soil is very large.

"Some years ago," adds the Professor, "I made an experiment with the view of ascertaining how much nitrogen was present after the clover crop had been removed; and I ascertained that, taking an acre as the experimental area, it was equivalent to rather more than the amount of nitrogen present in 8 cwt. of Peruvian guano. It has been found that the clover crop is the most excellent preparation for the succeeding wheat, and it is known now as a fact, that after growing a good crop of clover a very large amount of root is left in the soil."

The primary question in ploughing-in a green crop is of course the profit compared with consuming it by live stock. This inquiry has been carefully considered in three papers, which are contained in the recently published number of the Journal of the Royal Agricultural Society (vol. iv., pp. 99, 103, 107, N.S.), by Messrs. Peter Love, G. Murray, and W. E. Wright. Another use of one green crop—the white mustard—when ploughed into the soil, has been described by Mr. Love, viz., its action as a smothering crop, for the cleansing of foul clay soils.

As regards the comparative profit of green crops used as a manure, and as food for stock, Mr. Love observes (*ibid.*, p. 99):

"Thirty years ago the ploughing-in of green crops was more studied and practised than at the present, the introduction of guano, nitrate of soda, &c., and the extraction of fertilisers from refuse of every description by the aid of chemical science having since then done much to meet the wants of the farm. The high price of meat has also induced the farmer to consume all his green crops by stock.

"I remember that it was pretty generally recognised among intelligent farmers, that the ploughing-in of 18 tons of turnips per acre, after being crushed by a clod-crusher, gave 12 bushels of barley more than if the said turnips had been first passed through the animal, and the elements to form mutton and wool extracted; it is also pretty certain that a ton of turnips will produce 14 lbs. of mutton, and about 1 lb. of wool; but the outlay on sheep, risk of losses, and cost of attendance, must be taken into account.

"I have only once tested the difference of carting all off, feeding on, and ploughing-in turnips; this was early in 1842, when beef and mutton sold by the carcase at from 4d. to 6d. a-pound, and roots were superabundant.

"A 12-acre field of light loam subsoil, the Northampton ironstone, had been manured with about 16 tons of good fresh farmyard manure per acre, ploughed in 10 inches deep during the winter, with about 5 inches of wheat stubble, afterwards thrice cultivated in the spring, harrowed and rolled, then ridged-up, and two quarters of bone-dust (well fermented after wetting with urine) drilled-in per acre under the seed; the produce was a little over 18 tons of turnips per acre. The crop on 3 acres was all carted off the land, that on 7½ acres eaten by sheep, and that on 1½ acres crushed with a Crosskill's clod-crusher, then harrowed across the rows, re-crushed and ploughed-in 6 inches deep. The part eaten off was ploughed only about 3 inches; that where the turnips were drawn 6 inches; the whole was sown with oats, and produced as follows: where turnips were drawn, within a peck, under or over, of 7 quarters; where eaten, 9 quarters; where ploughed-in, over 11 quarters per acre. Each piece was carefully kept by itself, and all thrashed the same week, and sold to the same man, on the same day, at £1 per qr. They were harvested without wet, and weighed 41 lbs. per bushel.

"If we can accept the result of this one experiment, it tends to show that the virtue of the manure left in the excreta of the sheep is about equal to what is expended on making mutton and wool besides maintaining the animal's heat and existence. If we take the two quarters of oats as a fair equivalent to the 12 bushels of barley before mentioned, it follows that the entire manurial value of 18 tons of turnips ploughed-in is equivalent to 24 bushels of barley, or 32 of oats; or if these are valued respectively at 32s. and 24s. a quarter, is £4 16s. for £18 tons, or about 5s. per ton; or 2s. 6d. per ton for the excreta left by fattening sheep.

"Swede turnips, apart from their value as feed, are not well suited for ploughing-in as manure; they do not rot down well, though they be smashed with mallets. The clod-crusher will not break them, and the tops will strike root and grow, if any part of the crown of the bulb is left adhering to them.

"The results obtained," continues Mr. Love, "by ploughing-in turnips in 1842 induced me to try white mustard in 1843, on a small field of 8 acres; soil a stiff poor clay, upon blue lias clay subsoil, as foul with twitch as possible; it was ploughed about 7 inches deep in the winter, then scarified with broadshares about 8 inches deep the last week in March, and after being well harrowed, sown with white mustard-seed by a broadcast seed-barrow, at the rate of a bushel to 3 acres, covered in by very light seed-harrows. This crop was just breaking into bloom the last week in May, and 26 inches high, when it was ploughed-in about 4 inches deep, and 100 bushels of lime (after being slaked with salt and water) applied per acre; then after one turn of the Norwegian harrow, re-sown with mustard, care being taken that all ploughed-in within the day should be re-sown on the same day it was ploughed; all was finished on the last day of May.

"On the 8th of July we began ploughing-in 6 inches deep this second crop, which was above 46 inches high. About accomplishing this I had some misgivings at first, but managed it well by attaching a heavy block of wood, 12 inches wide, 18 inches long, drawn by a chain attached to the large whippetree, and dragged just under the plough beam, a few inches in advance of the coulter. This further served to regulate the depth instead of a wheel. We had also the usual drag weight and chain to lap the whole under the furrow. About six furrows at the last must be done with the horses at length, or else when the land horse returns on the same track as he went, he ricks and entangles the long stems so together that they lap round the coulter and choke the plough, causing much trouble, and making the work rough and untidy: by putting the horses 'at length' there is no trouble, except with the last two furrows. Immediately after ploughing we gave one turn of the Norwegian harrow, then re-sowed the mustard as before. The whole field was finished on the 12th of July.

"The third crop was just breaking into bloom on the 24th of August, and the length above 5 feet; this was ploughed-in 8 inches deep, with four horses at length, followed by a two-wheel presser, following only one plough, thereby giving each furrow a double go. After one turn of the Norwegian harrow, the land was left to settle down for the future wheat crop. As for the couch grass, except a few blades in the first crop of mustard, we saw no more of it, except the rotten roots, as we were ploughing the last crop in. After one turn of the Norwegian harrow in the first week in October, the land was drilled with two bushels of red wheat per acre, a light harrow following, then twice rolled with Crosskill's heaviest crusher: it was crushed again in March. The produce at harvest was all that any man could desire, and

perfectly clean. After one 8-inch winter ploughing, and a shallow scarifying in the following March, it was drilled with white oats and clover seeds; the crop of oats was magnificent, and in some parts injured the seeds. Thenceforth this field, which had borne a very bad character, behaved as well as the best. During the succeeding seven years of my occupation of this farm, if I had to deal with any piece of very foul strong land, I cleaned it in this way; but if it was moderately clean, I consumed the mustard with store sheep and lambs. Mustard crops grown after those eaten off will not be so heavy, but with a very little corn or cake they will keep from 16 to 24 sheep per acre, half ewes and half lambs, from the middle of May to the end of August, or even later. The ewes (or stores) should follow the lambs in a separate pen; a fresh piece should be given every day, and the piece fed off should be ploughed and sown the same day, because in dry seasons whenever the land is naked the moisture is soon dried up; thus there will be a regular succession, and also the almost certainty of a plant.

"The application of 1 cwt. of nitrate of soda to the first crop will almost double it, and, of course, much increase the two following crops, as well as their power to smother the twitch or other weeds. I know several persons who have made attempts at this system, but through dilatoriness in ploughing and re-sowing have failed to obtain a regular plant. I believe the Norwegian harrow to be indispensable to success, because it thoroughly pulverises the soil at once, so that lengthened exposure of the different surfaces is avoided, and much moisture saved that would be lost by repeated harrowing and rolling. If in a wet season rains falls and delays the sowing after any part is ploughed, this delay gives the half-dead twitch time to revive before the smothering influences of the next crop can overpower it; so that in either wet or dry seasons the mainspring of the whole system is promptness and punctuality in performing every part of the work thoroughly well, with the least possible mauling of the soil, so as neither to make dust in the one case, nor mortar in the other.

"I need scarcely say that trifolium, tares, trefoil, Italian ryegrass, or any other forward crop may be grown as a first crop; and after this is fed off, two crops of mustard may still be obtained either to eat off or plough in. The difficulty, nay, almost impossibility, of cleaning strong land in a wet season is well known to all practical farmers. Now I venture to affirm that the foulest and poorest possible piece of land (sand, perhaps, excepted) may be cleaned by growing white mustard, with 1 cwt of nitrate of soda per acre applied to the first crop, and three crops in succession ploughed-in, as before stated, let the season be either wet or dry. The soil will be left as capable of bearing a crop as if 20 tons of farmyard manure had been applied to a bare fallow.

"Whether sandy land, the natural parent of couch-grass, could be cleaned in this way I do not know; but I do know that all bog, fen, or peat, light gravel, or loam, and all clays can. It is almost superfluous to contrast the expense of this system against that of the bare fallow: but the case may be roughly stated as follows:

Cost of an acre of bare-fallow manured with 20 tons farmyard manure.

March ...	Winter ploughing ...	...	£0 12
April ...	Scarifying and harrowing ...	...	0 4
April ...	Cross-ploughing ...	...	0 12
June.....	Summer ditto ...	...	0 10

			£8 2

"When land is partially cleaned in the autumn, it may be perfectly cleaned and manured by growing three crops of mustard, to be folded; an acre will then keep an average of 20 sheep for 15 weeks, which will give a result as follows:

WHITE MUSTARD.		DL.
Cost of autumn cultivation ...	...	£1 0
Ditto as above for three crops ...	...	5 3
		<hr/>
Total cost of cultivation ...	...	£6 3
CONTRA.		DL.
20 sheep kept 15 weeks at 4d. a week each...	...	£5 0
Value of excreta left ...	...	3 10
		<hr/>
Gross return ...	...	£7 10
Cost of cultivation...	...	6 3
		<hr/>

Leaving to meet rent and taxes a balance of £1 7

"I therefore conclude that plants when at their greatest green bulk are worth about 5s. a ton to plough-in as manure, and if palatable for stock, they will make about 14 lbs. of meat, and the excreta left will be worth, as manure, about 2s. 6d. per ton of food consumed."

I have thus given nearly the whole of Mr. Peter Love's practical observations: his details of errors to be avoided, and of advantages to be reaped by the use of green manures on certain soils, will well repay the reader for a careful study. The agriculturist, I repeat, will note that we are here again treading in Nature's footsteps; it is by feeding on the carbon diffused in the atmosphere that the little plants attached to bare rocks or on the most barren soils support their existence, and by their death and decay gradually adding to the soil, the carbon which they derive from the atmosphere render it capable of supporting far larger and more valuable crops. Davy long since described the gradual formation of a soil in this way. After tracing the slow decomposition of a granite rock by the action of the atmosphere, he remarked that as soon as the smallest layer of earth is thus formed on the surface of the rock, the seeds of lichens, mosses, and other imperfect vegetables, which are constantly floating in the atmosphere, and which have made it their resting-place, begin to vegetate: their death, decomposition, and decay afford a certain quantity of organizable matter, which mixes with the earthy materials of the rock. In this improved soil more perfect plants are capable of subsisting; these in their turn absorb nourishment from water and the atmosphere, and after perishing contribute other materials to those already provided. The decomposition of the rock still continues, and at length, by such slow and gradual processes, a soil is formed in which even forest trees can fix their roots, and which is sufficiently fertile to reward the labours of the husbandman.

## THE NORFOLK AGRICULTURAL ASSOCIATION.

## MEETING AT DOWNHAM MARKET.

After a long lapse, the Norfolk Society was first again in the field at Fakenham with an agricultural show in its entirety; and it has this season just celebrated the most successful exhibition of its order that has yet been held. The far-west meeting of the West of England Society at Falmouth was comparatively a failure; the Berkshire and Hampshire gathering at Winchester depended mainly on the sheep for its merits; while the Islington Horse Show is too directly identified with the mountebank business to ever reach the dignity of a national institution of the kind we contemplate. Not that the illustration offered us at Downham was by any means perfect in its way. There were some sections of the show just as weak as there were others strong. Amongst the sheep and pigs, for instance, although there were many individual entries of much excellence, there was often little or no competition. Lord Walsingham, for one, has been advised, as he says—and badly advised, too—not to run for the first heat; in other words, his lordship cannot afford to exhibit any of his famous South-downs at his own county meeting because he intends exhibiting some of them at the Royal Meeting at Leicester. Surely, with the numbers they must have to pick from at Merton, this only proves a sad want of pluck. But let us go on to suppose, for the sake of argument, that Lord Sondes, Mr. Brown of Marham, and Mr. Hugh Aylmer declined to send their sheep to Downham because they will, as we believe, send some from their flocks subsequently to Leicester. What, under the influence of such very cautious tactics, would become of the Norfolk Show? Lord Sondes exhibited some very good Downs, his cup shearing being a particularly neat sheep, very true in his character, as bred from Mr. Webb and Sir William Throckmorton. But in two classes of rams there was only one single entry beyond his lordship's own—a shearing of Mr. John Overman's; and in the ewes, again, Mr. Overman and his Royal Highness the Prince of Wales, with a badly-done dark-faced pen, alone attempted to dispute the Elmham supremacy. The Down lambs, from want of roots or moisture, made pretty generally a very poor front, although Lord Walsingham mustered up courage enough to send one lot. With the Norfolk long-wools—or, as they are now called, Cotswolds—the contest was as usual confined chiefly to Messrs. Brown and Aylmer, although we are inclined to think that both may have better sheep kept back. Still Mr. Brown's ewes, bred from a ram of Mr. Robert Lane's, are particularly good sort sheep, and more uniform, indeed, than might have been expected. The Markham first-prize old ram has never been out before; but, to our thinking, he is a better-framed sheep than the second, that has won in his time, and was thought by many to be still the better of the two. In the other breeds, Mr. Henry Overman had the best of it with his Oxford Downs; but, despite the very limited competition, the real short-wools and long-wools went far to make the sheep-show.

It would appear that the Messrs. Sexton had this season a wonderful "growth" of pigs; and that their neighbour, Mr. Stearn, became cognisant of this very gratifying fact. But, as the Sextons have sold out early, and as Mr. Stearn did not enter, the pig prizes at Downham were left very much at the mercy of Mr.

Crisp and the Duckerings from Lincolnshire. Indeed, in the majority of the classes, there were no other entries, although Mr. Crisp varied the entertainment, so far as was possible, by taking one cup with a little black pig, and another cup with a little white pig, the Lincolns being more of course in the ascendant amongst the larger breeds, although they did send a Berkshire or two from Butley. But the merits of these pigs were in an inverse ratio to their numbers. Mr. Moon, and Mr. Moon is a judge, declared they were good enough to win in any company, as no doubt some of them have been doing already, and will do again. The Northropes are probably on the grand tour, and will in the course of the season see as much of this sort of thing as Mr. Thurnall, John Ward, or Mr. Sanday.

Mr. Sanday had scarcely elbow-room enough allowed him at Downham, and he did not look very happy in solitary confinement; but he got through his difficulties handsomely enough. There were only two really good animals amongst the sixteen or seventeen all-aged Shorthorn bulls; and these he placed first and second. The Cup bull, as the best of all the bulls. Mr. Lynn's prizeman, an own brother to Pamela, begins well with a good head and neck, and plenty of fine masculine character. Moreover, he both stands and moves well, being active enough, although very high in condition; he is short of coat, but of fine quality, and goes on to Leicester with every chance of some further notice. His second, Lady Pigot's Charles le Beau, looks little the worse for his long journey westward, and is a very taking animal at most points, but he wants the age to compete with the other. The best bull at Fakenham last year, and, as we then said, a very bad one at best, was quite out of it, although the chief labour must have been to find a third and a reserve. The Branches Rosolio had it still more his own way with the yearlings, where he, nevertheless, had to beat Mr. Martin's Hermit, that beat him at Wisbeach last summer. Hermit was now put quite aside, and the second prize awarded to a plain slack-backed beast of Mr. Kersey Cooper's, whose place did not say much for the other dozen in the class. Although fresh from her defeat down in the West, where the Shorthorn clearly flourishes, The Queen of Rosalia quickly righted herself in Norfolk, being at all points the best of her breed on the ground. And a sweet cow she is, with her kind head, round frame, broad back, and fine bone, so that the comparison with the second as they stood side by side was very emphatic. There were still plenty of entries here again, and Mr. Brackenbury took a prize and a commendation, and Mr. Gamble a commendation, and so forth. But Mr. Gamble does not get his stock up for show, and so of course he does not get prizes. Lord Walsingham's heifer in-calf was about the pick of the county, and very good indeed she is in places; but she is short, forward, and does not "set herself" to much advantage. Lady Pigot and Mr. Lynn come in again amongst the younger heifers, and it is very clear that, although some Shorthorn herds are being carefully cultivated in Norfolk, these have not yet made any great way.

The red Polled beasts were nothing of a show to that at Fakenham, and for choice we should have taken Lord Sondes' beautiful little

yearling heifer, as something very perfect alike for symmetry and character; but she was quite "out-paced" in her class, showing really as a yearling against animals some ten or eleven months older. Lord Sondes, indeed, had all the call here for quality, although we do not profess to say how far this goes in judging a polled milker. The Suffolks were well represented in perhaps the generally best class in the catalogue, that of cows in-calf or in-milk, where Mr. Walton, the only exhibitor beyond the confines of Norfolk, won with his old Favorite; but the competition in the other classes of polled stock was not great. Mr. Henry Overman still tries the Ayrshire cross, and with every reason, so far as the prize list of the other breeds can speak to the worth of this; while Mr. Wortley would appear to have taken to feeding Herefords in preference to Devons, and some very capital steers he has now in preparation. The fat stock, however, made a strong feature in the show, and what with Shorthorns, Poll-crosses, and Devons, should be heard of hereafter in the chronicles of the Smithfield Club. One of the best of these beasts, a fat cow exhibited by Mr. Durrant, and of the famous Shorthorn and Aberdeen "nick", was objected to, after having had the Cup awarded her for the best of all the fat cows, as having never had a calf; but we did not hear that she was disqualified.

The distinction drawn over the breeds of cart-horses is, like a few other features in the management of the Norfolk Society, somewhat eccentric. For example, the classes of cart-horses, that is to say cart-horses generally, are made to include Shires, Suffolks, and so forth, while the Norfolks have a section to themselves. Whereas at other shows the Suffolk chesnuts have a separate classification, and the bays and browns encounter, as they are no doubt occasionally crossed with, each other. We should not attempt to define a Norfolk cart-horse; but from their appearance should imagine that the breed is not kept very strictly to any one particular kind. The Committee put on Mr. Thompson, a Suffolk breeder, in the open classes, and he began courageously enough by reversing some previous decisions. Mr. Boby's Conqueror, the first prize Suffolk stallion at the Royal Bury Show, was never noticed at Downham, although Mr. Crisp's Captain, the second at Bury, was second again at Downham; and everybody seemed to think that Mr. Thompson was right, and that the Royal was wrong. But Mr. Thompson went a deal further than this, and gave not only the first prize of the class, but the Cup, as the best of his three classes of stallions, to Mr. Rist's Harwich Emperor, a horse that some time since was disqualified, by a veterinary surgeon, for side-bones. However, they do not recognize the office of a veterinary inspector at the Norfolk shows; and as the judge did not admit that the good-looking son of old Emperor ever had side-bones, of course he took all the prizes and medals and cups that his appearance otherwise so well warranted. His chief opponent, indeed, was not a chesnut, but a Shire colt in the next lot of three-year-olds; and it must have been a very near thing between the two; for Honest Tom has gone on improving since he won at Bury last year, and, although still rather a flashy horse, has a plenty of power, with quick action. He has never been beaten, we believe, until the Cup went against him here; but he had the credit of beating in turn the Suffolk President, the cup-horse of last season, when only a two-year-old. The stallions of this age at Downham were all Suffolks, as was the best mare, Mr. Walton's Violet, a son of Canterbury Pilgrim, and herself a Royal second. The cart-foals, either Norfolks, Suffolks, or Shires, were poor, as the want of rain must have told against their growth; but the Norfolk cart-mares made up a capital class, with two of Mr. Edwards', much of a muchness, first and second; and the

working pairs again were worthy of the county. It was the hardest part of Mr. Sexton's day's work to cull them; but he did so very satisfactorily, although they would have shown far better with more room to move in.

The same may be said, yet more emphatically, of the hackney ring, if it can be so called, in which really clever hacks and ponies swarmed in, one after and one alongside of the other, until it became a matter of much astonishment as to how Mr. Parson ever contrived to see half of them, let alone keeping clear of them. The entry of ponies between thirteen and fourteen hands was one of the best we have seen for some time past; and although the judge may have got to the two best of them, there were plenty still to pick from. The two classes of hacks were as good, and the two chesnuts in the over-fifteen hands lot, either for style or action worthy of their places almost anywhere, as first and second. In the next division, the fact that Mr. Badham's famous old grey Major could get no nearer than second, speaks something as to the excellence of his company; whilst amongst other old favourites, Mr. Robert Alymer's chesnut, at 24 years of age, was the second best broodmare, and Mr. E. Farrer's Little Wonder the best pony stallion. But the award over the stallions for saddle or harness, that is where the trotters came into competition, sent all Norfolk home again in sackcloth and ashes. There were Trotaways, Fireaways, Phenomena, and Quicksilvers. There were real show horses, that ran out as much line as a twenty-pound pike, and that lifted their legs to a continual chorus of *Hie, Hie!* and *Ho!* and *Ho!* And the prize alas! went away from all these to a handsome "real gentleman," with all the air and carriage of a thorough-bred horse, and with action as true and good as anything, if he did not make so much fuss over it. Sir Tatton Sykes bred him; he is by Fandango, out of Star by Bay Middleton, and Mr. Crisp has quartered him at Butley, to improve the breed of horses "for saddle and harness."

The best stallion in his own proper class, Sir Thomas Beauchamp's Aconite, is still handsomer, for he shows more blood, and what with his clean wicked head, light well-arched neck, and good back, is a really beautiful topped horse; while, as a rich brown, or black-brown, he would be sure to take about the country. Neither Mr. Stiggins nor the Abbot had a chance against him, although the judge hung terribly over his work. The four classes of hunters were pretty generally indifferent; but Mr. Gamble's old horse has earned his character in the field, and Mr. Sewell showed a very nice chesnut mare, that went too short and tender, or she might have stood higher. The weight-carriers were an under-bred lot, with one or two of them got by trotting horses, and the winner fed as high as a prize ox. He would have looked and gone all the better for a long sweat or two. The three and four year olds were but moderate, and we doubt if a dealer could have done much business in this way.

The implement show is mainly made up by local manufacturers and agents, with nothing beyond a few medals for distribution at the discretion of the judge, to whose awards the prize list will speak. Prominent amongst these awards was one for a combined straw-elevator and stacking machine, exhibited by Amies and Barford, that would promise to "take" on large farms. The dinner appears to have gone rather tamely, especially after the exciting speeches from the chairman and others at Fakenham. But although Sir William Bagge and Mr. Sewell Read were on the ground in the morning, they had to leave at noon, in order to be in time for the debate over the Foreign Cattle Market Bill, which, provokingly enough, never came on after all.

## PRIZE LIST.

## JUDGES:

Shorthorn, Cross-bred, and Fat Cattle.—W. Sanday, Holme Pierrepont, Notts.

Polled Cattle.—W. Horn, Debenham, Suffolk.

Cart Horses (except Norfolk).—W. Thompson, jun., Thorpe-le-Soken, Essex.

Norfolk Cart Horses.—G. M. Sexton, Wherstead, Suffolk. Thoroughbred and Hunting Horses.—S. J. Welfitt, Tathwell, Lincoln.

Harness Horses, Hacks, and Ponies.—G. F. Parson, Walldidfield, Suffolk.

Southdown Sheep.—H. Legar, Ingham, Suffolk.

Long-wooled Sheep.—W. Bartholomew, Waddington Heath, Lincoln.

Pigs.—J. Moon, Plymouth, Devon.

Implements.—T. Chambers, jun., Colkirk, Norfolk.

## CATTLE.

Shorthorn bull, £10 and silver medal, and cup value £10, J. Lynn, Stroxton, Lincoln (Prizeman); second, £8, Lady Pigot, Branches Park, Suffolk (Charles le Beau); third, £5, H. Aylmer, West Dereham (General Hopewell); commended, C. Beart, Stow Bridge (Forester).

Yearling shorthorn bull, £5, Lady Pigot (Rosolio); second, £3, G. Kersey Cooper, Euston (Hogarth the Second); highly commended, H. Aylmer (Prince Hopewell); commended, Wm. Goulder, Wimbotsham (Master Hopewell), J. How, Denver (Rapert).

Shorthorn cow, in calf or in milk, cup value £10, and £10 and silver medal, Lady Pigot (Queen of Rosales); second, £8, J. How, Broughton, Hunts (Jolly Queen); third, £4, W. T. Brackenbury, Shouldham Thorpe (Rosebud); commended, J. Gamble, Shouldham (Chance and Fame), W. T. Brackenbury (Lady Booth), and G. E. Frere, Roydon (Tibbie Tudor).

Shorthorn in-calf heifer, not above three years old, £5 and silver medal, Lord Walsingham, Mertou (Thoughtless); highly commended, G. E. Frere (Sugar Blossom); commended, T. Crisp, Batley, Suffolk (Dahlia).

Shorthorn heifer, in calf or in milk, under three years old, £6 and silver medal, Lady Pigot (Dame of Rosales); second, £4, J. Lynn (Aurora); highly commended, T. Crisp (Seraphine 5th); commended, J. Gamble.

Yearling shorthorn heifer, £4, J. How (Lady Anne); second, £3, Lord Walsingham (Daphne); highly commended, H. Aylmer (Phillis 6th).

Norfolk and Suffolk red polled bull, £10 and silver medal, and Downham cup value £10, B. Brown, Thursford, Norfolk (Duke); second, £8, Lord Sondes.

Yearling Norfolk and Suffolk red polled bull, £5, Lord Sondes; no second award.

Norfolk and Suffolk red polled cow, in calf or in milk, £10 and silver medal, S. Wolton, Newbourn, Suffolk (Favorite); second, £6, J. Hammond, Bale (Butler); third, £4, J. Hammond (Lady Davy); highly commended, J. Hammond (Moss Rose); the class commended.

Norfolk and Suffolk red polled heifer, in calf or in milk, under three years old, £6 and silver medal, W. Oliver, Docking; second, £4, B. Brown (Cherry); highly commended, Lord Sondes; commended, Lord Sondes.

Yearling Norfolk and Suffolk red polled heifer, £4, and cup value £10, for the best animal in the three classes, B. Brown, Hadsom; second, £3, Sir W. Jones, Bart., Cranmer Hall (Primrose); commended, Lord Sondes.

Polled cow or heifer, in calf or in profit, not being Norfolk and Suffolk red polled, premium of £5 and silver medal, H. H. Blomfield, Stoke Ferry (Handsome).

Horned cow, not being shorthorn, Devon, or Norfolk and Suffolk red polled, in calf or in milk, £5 and silver medal, H. Overman, Weasenham (Doat's Eye); second, £3, Captain Cating, Needham Hall, Cambridge; commended, W. Ellis, Wymondham (Rose).

Heifer, in calf or in milk, not being shorthorn, Devon, or Norfolk and Suffolk red polled, under three years old, £5 and silver medal, H. Overman (Kind); second, £3, M. Green, Roxham; commended, P. J. Sharman, Scarning (Victoria).

Yearling heifer, not being shorthorn, Devon, or Norfolk and Suffolk red polled, £3, G. M. Nicholson, Elmham.

Fat steer of any breed, above three years old, £8 and silver

medal, and cup value £10, B. Wortley, Suffield; second, £5, J. B. Aylmer, Fincham; highly commended, W. Coleman, Runhall; commended, W. Goulder.

Fat steer of any breed, not above three years old, £8 and silver medal, R. Wortley; second, £5, J. B. Aylmer; commended, J. How and E. Durrant, Wimbotsham.

Fat cow, above three years old, £5 and silver medal, and cup value £10, E. Durrant, Wimbotsham.

Fat heifer, not above three years old, £5 and silver medal, R. Wortley; second, £3, J. B. Aylmer; highly commended, W. Betta, Fincham, for two.

Extra Stock: Commended, P. J. Sharman, Scarning; highly commended, W. A. T. Amhurst (Bretonne Hereford bull).

## CART HORSES.

Stallion, not under four years old, £10 and silver medal, and cup value £10, I. Risk, Tattingstone, Suffolk (Harwich Emperor); second, T. Crisp (Captain).

Three-year-old stallion, £8 and silver medal, W. Welcher, Upwell, Cambridge (Honest Tom); second, £5, W. Wilson, Baylham, Suffolk (The President).

Two-years-old stallion, £6 and silver medal, C. Boby, Stutton, Suffolk; second, £4, W. Wilson.

Cart mare, cup value £10 and premium of £10 and silver medal, S. Wolton, jun. (Violet), second, £8, R. Gillett, Halvergate (Sprite), third, £4, J. Warth, Sutton, Ely (Diamond).

Three-years-old cart filly, £6 and silver medal, S. Wolton, jun. (Matchett).

Cart foal, £5 and silver medal, S. Wolton, jun.; second, £3, S. Delf, Christchurch, Upwell.

Fair of cart horses, whether mare or gelding, best suited for agricultural purposes in Norfolk, and which have been so used in the county for twelve months next before the exhibition, cup value £20 and silver medal, H. Overman; second, £6, the Executors of the late J. Smith, Crownthorpe; third, £4, J. Tingey, Ellingham.

Norfolk cart horses, stallions, not under four years old, £10 and silver medal, H. Overman (The Norfolk Lion); second, £7, T. Wright, North Ranton (The Norfolk Champion).

Three-years-old stallion, £8 and silver medal, cup value £20, J. B. Aylmer; second, £5, E. Gilbert, Blofield (Duke).

Two-years-old stallion, £6 and silver medal, C. Mainprice, Ely (No competition).

Mare, cup value £10, premium of £5, and society's premium of £5 and silver medal, C. Edwards, Stowe (Bounce); second, £6, C. Edwards (Pink); third, £4, E. Crowe, Denver; highly commended, J. B. Aylmer (Beauty), J. E. Groom, Congham (Jewel); and H. Overman (Brag).

Three-years-old colt. No merit.

Three-years-old filly, £6 and silver medal, W. A. T. Amhurst, Didlington; second, £3, J. Tingey (Brag).

Two-years-old filly, £5 and silver medal, F. Cambridge, South Ranton; second, £3, W. Blomfield, Stoke Ferry.

Foal, £5 and silver medal, the Executors of the late J. Smith; second, £3, J. Tingey.

Hunters, thoroughbred stallion, cup value £10 and premium of £10 and silver medal, Sir T. P. Beauchamp, Bart., Langley (Aconite); second, £6, T. Crisp (Abbot).

Mare or gelding, adapted for hunting, equal to 14 stones, £10 and silver medal, G. S. Hall, Ely (Little John); second, £5, J. Gedney, Ranton Holme.

Mare or gelding, adapted for hunting, not equal to carry 14 stones, £10 and silver medal, and the Prince of Wales cup value £20, J. Gamble (Pliable); second, £5, A. Hamond, Westacre (Tim).

Four-years-old colt or filly, adapted for hunting, cup value £10 and silver medal, T. Goold, Swaffham (White Stockings); second, £5, W. Goulder.

Three-years-old colt or filly, adapted for hunting, cup value £10 and silver medal, G. S. Hall (Young Sir Roger).

Harness horses, hacks and ponies—stallion for saddle or harness, cup value £20 and silver medal, T. Crisp (Fandangero); second, £10, T. L. Reed, Downham (Trotaway); third, £6, R. G. Beart, Raynham (Fireway).

Best riding mare or gelding, above 15 hands and not exceeding 15 hands and 3 inches high, £10 and silver medal and the cup value £10, S. Delf, Upwell, Cambs; second, £5, E. Durrant, Wimbotsham (Madeline).

Hackney mare or gelding, above 14 and not exceeding 15

hands high, £10 and silver medal, Rev. W. F. Thureby, Bergh Apton, Dagmar; second, £5, G. D. Badham, Bulmer Tye, Suffolk (Major); highly commended, J. Groom, Ashwicken (Topsy).

Brood mare, for saddle or harness, £8 and silver medal, R. Hubbard, Stow; second, £5, R. B. Aylmer, Westacre.

Entire pony, not under 12, nor above 13½ hands high, cup value £5, and silver medal, E. Farrer, Sporie (Little Wonder).

Pony, not under 13 nor above 14 hands high, £5 and silver medal, and cup value £5, R. B. Aylmer (Jack); second, £3, E. Larke, Wymondham (Duchess); highly commended, J. Warth, Sutton, Ely (Matchless).

Pony, not under 12 nor above 13 hands high, £5 and silver medal, J. J. Clarke, Swaffham (King of Hearts); second, £3, H. Bullard, East Carleton (Jacob).

Cob, showing the best walking and trotting action under a rider weighing not less than 15 stones, saddle and bridle included (height not less than 13½ hands, nor more than 15 hands), £10, and cup value £10, and silver medal, H. Martin, Littleport, Isle of Ely.

Extra Stock.—Commended, T. Wright, North Runcton (pony).

### SHEEP.

Shearling Southdown ram, £8 and silver medal, and cup value £10, Lord Sondes; second, £5, Lord Sondes.

Southdown ram of any age, £5 and £3, and silver medal, Lord Sondes.

Pen of five shearling Southdown ewes, £5 and silver medal, Lord Sondes; second, £3, Lord Sondes.

Pen of ten Southdown ewe-lambs, cup value £10 10s., and premium of £4 and silver medal, Lord Walsingham; second, £3, Lord Sondes.

Pen of ten Southdown wether-lambs, bred by the exhibitor, £5 and silver medal, Lord Sondes; second, £3, Lord Sondes.

Shearling long-woolled ram, £8 and silver medal, H. Aylmer; second, £5, T. Brown, Marham; third, £3, T. Brown.

Long-woolled ram of any age, £8 and silver medal, and cup value £10, T. Brown; second, £5, T. Brown; third, £3, H. Aylmer.

Pen of two long-woolled rams, £5 and silver medal, T. Brown; second, £3, T. Brown.

Pen of ten ewe or wether-lambs of any other breed, £5 and silver medal, J. Hammond, Bale; second, £3, J. Hammond.

Pen of two ram-lambs, not being long-woolled, bred by exhibitor, £4, and silver medal, J. Hammond.

Pen of three shearling wethers of any breed, £5 and silver medal, H.R.H. the Prince of Wales; second, £3, J. T. Ashley, Litcham.

Pen of ten ewes of any age or breed, £5 and silver medal, T. Brown; second, £3, T. Brown.

Pen of ten ewes of any age or breed, not being Southdown or long-woolled, £5 and silver medal, H. Overman; second, £4, H. Overman.

Pen of five shearling ewes of any breed, not being Southdown or long-woolled, £5 and silver medal, H. Overman; second, £3, H. Overman.

Pen of twenty shearling ewes of any breed, without restriction as to clipping, £5 and £3, and silver medal, Lord Sondes.

### PIGS.

Boar of large breed, £4 and silver medal, R. E. Duckering, Northorpe, Lincoln; second, £2, R. E. Duckering.

Breeding sow of large breed, £4 and silver medal, R. E. Duckering; second, £2, T. Crisp.

Boar of small breed (black), cup value £5, and £4 and silver medal, T. Crisp.

Breeding sow of small breed (black), £4 and silver medal, T. Crisp.

Boar of small breed (white), cup value £5, and £4 and silver medal, T. Crisp; second, £2, R. E. Duckering; highly commended, R. E. Duckering and H. Aylmer.

Breeding sow of small breed (white), £4 and silver medal, T. Crisp; second, £2, R. E. Duckering.

Three breeding sows of small breed (black), not exceeding nine months old, £4 and silver medal: no merit.

Three breeding sows of small breed (white), not exceeding nine months old, £4 and silver medal, H. Aylmer.

### IMPLEMENTS.

Silver medals to Amies, Barford, and Co., of Peterborough, for combined elevator—Hambling and Son, East Dereham, for self-feeding thrashing-machine—Barnes, Wells, for wall-tube—Le Butt, Bury St. Edmund's, for hand seed-drill—Hornaby and Son, Grantham, for turnip-cutter.

Highly commended: Corbett's combined blowing, windowing, and screening machine; Amies and Co.'s iron frame grinding mill and oilcake mill; Holmes' combined portable thrashing-machine; Woods and Co's horse-works; Wilkinson's self-regulating horse-hoe.

Commended: Sainty's sheep and cattle permanent or portable fencing; Woods' chaffcutter; and Hornaby's root pulper.

### THE DINNER.

was held on Thursday, when about two hundred attended. The chair was filled by the President of the Association, Mr. W. A. Tyssen Amhurst. In the course of the proceedings

Lord WALSINGHAM expressed the regret with which he had heard that their Members were not able to be present with them at that dinner; because they were all extremely anxious to come, and nothing but a very important measure which was in Parliament, and which concerned agriculturists, would have detained them. There was a bill before the House of Commons, which proposed to establish a market by the side of the Thames for foreign cattle, and for foreign cattle only; and it also proposed to provide that foreign cattle brought over here for the purpose of being turned into food should be immediately slaughtered, while if they were intended for store stock—of which not many would come, because they had very good stock of their own, and did not want to go to their neighbours, but supposing any should come for people who wish to have a particular species, such as Chinese sheep, of which he had some, or a Roman bull—they would have to undergo certain quarantine. The Metropolitan Market would then be left entirely free, and they would hope to get rid of all restrictions with respect to animals removed from the Metropolitan Market, so that their trade would be as free as it was before the incoming of that formidable disease, rinderpest; and they would not be in fear of any danger of having it re-imported into this country, for it undoubtedly came from abroad—from the Continent—and not only rinderpest, but pleuro-pneumonia and foot and mouth disease, through which they had lost such an enormous number of their fine, magnificent cattle, such as they had seen that day at the Show. He believed the only way of doing this was the way proposed; but he might tell them the bill would meet with great opposition, and it was somewhat doubtful whether it would be carried, and he was, therefore, sure they would feel, with him, that their members were doing their duty more thoroughly by attending the House to support this bill than by coming to enjoy themselves with them, as he was sure they would have enjoyed themselves. If he (Lord Walsingham) had not been able to show so many sheep this year as he had upon some former occasions, it was because the competition was so great; and he had been advised he ought to reserve his horses during the first heat, and so he had allowed his noble friend Lord Sondes to walk over the course, as he so well could do. They knew he was afraid of him; but he should have pluck enough to meet him at Leicester, where he should stand a better chance, from not having worked his horses too hard in the first heat.

Mr. J. S. WELFITT responded to the toast of "The Judges of Horses," and, in doing so, remarked that he thought it would be more satisfactory to the public at large, and would take considerable onus off the shoulders of one gentleman, if there were two judges another year.

Mr. MOON replied to the toast of "Judge of the Pig class," and expressed his belief that if the show had been larger the pigs that took the prizes would not have been beaten, as they were of such excellent character. He differed from Mr. Welfitt's opinion as to two judges, and thought one judge only was sufficient and best, because where you had one judge there was no calling in a third person: the judge was put upon his metal, and could not shirk. Where they had two or three judges, one might be told he had done wrong, and he could easily say that it was not his fault; the other judges did it, and he was obliged to give way. He was glad Norfolk had introduced the system of having but one judge, and hoped the course would be universally adopted.

Mr. WELFITT agreed with the remarks of Mr. Moon, and was in favour of all other classes except horses having but one judge. He said there existed a difference of opinion with respect to horses which did not exist with regard to other animals.

Mr. T. CHAMBERS acknowledged "The Judge of Implements," remarking that the principal novelty in the show-yard among the implements was "Norton's American tube-

well," which, he thought, in many cases would be of great value.

It will be seen that great difference of opinion exists as to the plan of single judges, many of the Committee of the Association being opposed to it, and a number of gentlemen who were invited to act in this way having declined to do so.

## THE THORNE AGRICULTURAL ASSOCIATION.

The sixteenth annual show has just been held, and in every point has proved more successful than any of its predecessors.

The section which excited the most interest was the horsering during the awarding of the prizes, and in this, especially in Yorkshire, most important department of the exhibition, the number of entries was very large, and the quality exceedingly good. The entries were no less than 60 in excess of last year, and included some very fine animals. The classes which attracted particular attention by their excellence were the hunters, roadsters, lady's hacks, and draught-horses, the latter calling forth praise from every side. In the class for two-year-old geldings or fillies for agricultural purposes, the prize was taken by a capital colt exhibited by Mr. S. Waterhouse, Doncaster. The whole class was a very good one, as was also the next one-yearling, hunting colt or filly. The collection was indeed so excellent that it was some time before the judges could decide. A beautiful little chesnut, by Wild Hero, was very much admired, the only fault being that he was too small. The first prize taken was by Heber, out of a mare by Era, exhibited by Mr. T. Perkins, Snaith, and the second, by Arribas, shown by Mr. R. Bulay, Hooton Pagnell. The two-year-old hunting geldings or fillies were also an excellent class, and the prize was taken by a magnificent one exhibited by Mr. Godfrey, but which had nearly been disqualified by being wrongly entered. For the prize in the three-year-old hunting, gelding, or filly class, there was a very good competition, and even the judges could not agree for a long time as to whether 187 or 171, both by Arribas, should take the first; finally, however, 171, shown by Mr. W. Glentworth, obtained the honour. In the competition for the silver cup, given by Messrs. Durham, Foster, and Shaw, for the best three-year-old gelding or filly for agricultural purposes, a famous lot of animals appeared; Mr. William Tennant, of Baslow, being successful in taking the first prize. The next class consisted of pairs of draught-horses, and here the quality could not be excelled. A couple of superb greys, one by John Bull, exhibited by Mr. Brierley, of Middleton, carried off the cup, and they were the admiration of all who saw them, the judges expressing an opinion that there could be nothing better. The silver cup for the best roadster nag or mare was taken by Mr. Winter, Goodoop; the cup for the best lady's hackney by Mr. G. Wakefield, Keadby; and for the best pony not exceeding 14 hands, by Mrs. Milward, Thurgarton. The extra stock contained one of the best horses on the ground; this was a gelding exhibited by Mr. J. Robson, Malton, and to it a first prize was awarded. Turning next to cattle, we may state this was the first show since the cattle plague, and was a very good one. Some useful bulls were shown, but it was in the cow class that the greatest excellence was to be found. Mr. Whittaker exhibited a very fine pair of heifer calves, which took the first prize, and in the sheep department he also took the silver cup for the best pen of long-woolled Leicester gimmers. The ewes were a very good class, and the show altogether excellent. For pigs the entries were not numerous, but the quality could not possibly be better. The competition, however, was confined to two exhibitors, Mr. John Dyeon, of Leeds, and Mr. R. E. Duckering, of Northorpe, who took all the first and, with one exception, all the second prizes between them. The show of dogs was really remarkable, and it is very seldom that such a collection is brought together. The extra prizes and the many "commendeds" which the judges bestowed come as quite a sufficient proof of their general excellence. One class in particular, the fox-terriers, were specially noticed, and Mr. J. Denton, of Doncaster, took the first prize.

## PRIZE LIST.

### JUDGES.

Horses—J. Robinson, Grove House, Manchester; T. Stamper, Highfield House, Oswaldkirk; T. R. Colton, Eagle Hall, Newark.

Beasts, Sheep, and Pigs—G. Bland, Coleby Hall, Lincoln; R. Foxton, Walburn, Kirbymoorside; T. Dodds, Mount Pleasant, Wakefield.

### IMPLEMENTS.

The best assortment of farming and other implements manufactured and exhibited by any one person.—1st, Vickers, Snowden, and Morris, Doncaster; 2nd, B. Sanderson, Thorne.

### HORSES.

Mare and foal for agricultural purposes.—1st, W. Tennant, Barlow; 2nd, M. Askern, Levels.

Mare and foal, hunting.—1st, H. W. Godfrey, Bank House; 2nd, M. Askern.

Mare and foal, carriage.—1st, M. Askern; 2nd, Messrs. Reynolds, Carlton; highly commended, T. Wakefield, Messingham.

Mare and foal, roadster.—1st, H. W. Godfrey; 2nd, J. Lee, Thorne.

Yearling colt or filly for agricultural purposes.—1st, F. T. Turner, Armthorpe; 2nd, J. Coulman.

Two years old gelding or filly for agricultural purposes.—1st, S. Waterhouse, High Ellers; 2nd, T. H. Goulton, Airmyn Grange.

Yearling colt or filly, hunting.—1st, T. Perkins, Snaith; 2nd, Bulay, Hooton Pagnell; highly commended, P. Dogherty, Airmyn.

Two years old gelding or filly, hunting.—1st, H. W. Godfrey; 2nd, J. Reader, Holme; highly commended, J. Kelsey, Garthorpe Grange.

Three years old gelding or filly, hunting.—1st, W. Glentworth, Goole; 2nd, H. Soer, Bawtry; the class commended.

Yearling colt or filly, carriage.—1st, W. H. Godfrey; 2nd, M. Askern; commended, H. Cooke, Carlton.

Two years old gelding or filly, carriage.—1st, H. W. Godfrey; 2nd, S. Waterhouse.

Carriage gelding or mare of any age.—1st, T. C. Glazier, Amcotts; 2nd, W. B. Houlden, Cantley; highly commended, W. Brockton, Tudworth; the class commended.

Yearling colt or filly, roadster.—1st, F. Long, Spofforth; 2nd, W. Whaley, Thorne.

Two years old gelding or filly, roadster.—1st, T. Baddiley, Hatfield; 2nd, E. Coulman, Plains House; highly commended, M. Durham, Thorne.

Three years old gelding or filly for agricultural purposes, a silver cup, value £5.—1st, W. Tennant; 2nd, G. Wood, Hayfield; highly commended, J. Bramley, Barlow; commended, J. Winder, Newton.

Pair of draught horses, of any age or sex, a silver cup, value £6.—1st, C. W. Brierley, Middleton; 2nd, Messrs. Crawshaw and Blakeley, Dewsbury; highly commended, R. Mickelthwaite, Thorne; commended, E. Coulman.

Draught horse, of any age or sex.—1st, W. Tennant; 2nd, J. Wood, Sykehouse; highly commended, J. B. Milman, Levels; commended, M. Askern.

Roadster, nag, or mare of any age, a silver cup, value £6.—1st, E. Winter, Goodoop; 2nd, G. Wakefield, Keadby; highly commended, R. Barker, Malton; commended, T. Wakefield, Messingham.

Lady's hackney, of any age or sex, a silver cup, value £5.—1st, G. Wakefield; 2nd, W. M. Darley, Thorne.

Pony, not exceeding 14 hands, silver cup, value £3 3s.—1st, R. Milward, Thurgarton; 2nd, W. White, Crowtrees.

Pony not exceeding 12 hands.—1st, E. Rogers, Rockley; 2nd, C. Dook, Levels.

Sucking foal by Gavazzi, a special prize.—1st, G. Gillatt, Doncaster.

Yearling by Antwerp, a special prize.—1st, J. H. Dean, Stainforth.

Sucking foal by Antwerp, a special prize.—1st, M. Askern.

EXTRA STOCK.—1st, J. Robson, Malton; commended, W. White.

### CATTLE.

Bull of any age.—1st, J. Mann, Sprothro'; 2nd, B. J. Whittaker, Hesley Hall.

Bull under two years old.—1st, G. Cattle, Hooton Levett; 2nd, J. S. Barn, Streethorpe.

Cow in calf or milk for daily purposes.—1st, — Dickinson, Partridge Hill; 2nd, B. J. Whittaker; commended, J. Sykes (Bramwith), J. Elliott (Levels), E. Barker (Pigburn), W. Brockton, J. F. Watson (Crowle Wharf).

Heifer in calf or milk, under three years old.—1st, B. J. Whittaker; 2nd, W. Brockton; commended, J. Aldam, Epworth.

Pair of calves, above 12 and under 18 months old.—1st, B. J. Whittaker; 2nd, J. Elliott.

Pair of calves, above 6 and under 12 months old.—1st, J. Coulman.

### SHEEP.

Long-woolled or Leicestershire ram of any age.—1st and 2nd, J. F. Moorhouse, Penistone; commended, J. Ingham (Marr), H. Poskitt (Darrington).

Shearling long-woolled or Leicester ram.—1st and 2nd, R. C. Workman, Almholme.

Five long-woolled or Leicester ewes, having suckled lambs until June 17, 1868.—1st, J. Winder; 2nd, E. Turner; commended, R. C. Workman.

Five long-woolled or Leicester gimmers, bred by the exhibitor within a distance of 20 miles of Thorne, a silver cup, value £5.—1st, B. J. Whittaker; 2nd, M. Astern.

Five long-woolled or Leicester wedders.—1st, L. Baxter, First Courtney; 2nd, R. Law.

Five lambs.—1st, H. W. Godfrey; 2nd, R. M. Waterhouse, Armthorpe; commended, J. Warriner, Wroot.

### PIGS.

Boar of the large breed.—1st, J. Dyson, Leeds; 2nd, R. E. Duckering, Northorpe.

Boar of the small breed.—1st, J. Dyson.

Sow of the large breed.—1st, J. Dyson; 2nd, R. E. Duckering.

Sow of the small breed.—1st, J. Dyson; 2nd, R. E. Duckering.

Sow of the middle breed.—1st, J. Dyson; 2nd, R. E. Duckering.

Three store pigs.—1st, R. E. Duckering; 2nd, E. T. Whaley.

Open gilt of any breed, not less than 6 or more than 12 months old.—1st, R. E. Duckering; 2nd, J. Dyson.

## THE NORTH-EAST AGRICULTURAL SOCIETY.

### MEETING AT BELFAST.

This annual show was held on Thursday and Friday, June 18 and 19. All the classes, with the exception of pigs, were good; and in that quarter the decline was in numbers, and not in quality. The show of Shorthorns and other distinct breeds of cattle and sheep was such as to do credit to any show in the United Kingdom for quality and breeding. There were forty-nine entries of Shorthorns of all ages. Six Shorthorned bulls, over two years old, competed in the first section, which ended in Mr. Ellison Macartney's four-year-old bull FitzJames being placed first; he comes from the now famous Castlegrave herd. Mr. Maxwell's Chancellor and Mr. W. Charley's Ulysses were second and third. The section for two-year-old bulls was made up of seven entries, Lord O'Neill's Lord of the Manor leading the way. Mr. Mulholland's bull Raven, by Ravenspur, was placed next, but he had a smart tussle with Mr. M'Crea's Northern Ensign, by Northern Chief; while Mr. Moody's Roger stood highly commended. There were 12 entries in the yearling bull section, the Marquis of Downshire's Marquis of Kildare, bred by Mr. Beynell, taking the lead, and also the Ulster Challenge Cup for the best animal in the short-horn classes. Mr. Maxwell's Prince Royal stood next; and the Earl of Dartry's Lamp of Florence, from the Ardert herd, made a capital third. An H. C. was given to Messrs. F. and W. Smith's Jemmy, a son of Fitzjames the Second. The male sections finished in the bull calves. The Earl of Dartry's Royal Butterfly—a beautiful white, only three months old—bred by himself, led off, followed by Mr. Ellison Macartney's White Rock, also bred by the exhibitor. The gem section of the show would be the cows of any age. The three prize ones were grand creatures, but of such different styles of sweetness and beauty as to render it most difficult and perplexing to place them, and the judges found it so; however, it ended in Mr. C. P. Les-

lie's Banshee being put first, his Lily of Warlabry third, and Mr. Maxwell's Anita second. Banshee, the first prize, is a grand cow of great substance, Lily of Warlabry is every inch a shorthorn, and Anita one of the sweetest and loveliest matrons we have seen. The three-year-old section contained but two, Mr. Mulholland's Elfin Dorrit being placed first, and Mr. Richardson, of Kircassock, second for Lady Frances. The two-year-old section contained three entries, Mr. M'Corkell's Rose of Warlabry, bred by himself, and Sir R. Bateson's Red Rose, bred by A. Warburton, Kill, being first and second respectively, Mr. George Callwell's Beauty the Sixth making a very handsome third. Four entries composed the section for yearlings—the Earl of Caledon's Countess, placed third at the last Dublin Royal, Mr. Maxwell's Princess Victor, and Mr. Charley's Princess Adelaide, being placed first, second, and third respectively. The Earl of Dartry exhibited a very nice heifer-calf, but there was no competition.

The northerners are great admirers of Ayrshires as dairy cattle. Six males and twenty-nine females, of all ages, were exhibited in the Amateur Class. They were well and purely bred, and, to all appearance, very suitable to dairy purposes. The Devons were the best we have seen for some time in Ireland, and numbered five males and ten females of all ages; and they are evidently favourites with those who possess them. The diminutive, yet profitable, Kerries numbered three males and three females; and Polled and Alderneys numbered but four of both sexes.

A new class has been opened for thorough-bred horses, which brought before the public on this the first occasion four very handsome well-bred gentlemen, and on the next occasion it is expected that this class will be yet better filled. In this, the Amateur Class, agricultural sires, mares, and other draught horses useful for general pur-

poes, were very well represented, numbering in the aggregate about 24 entries.

The sheep shown were about the best we have seen here; Leicesters, Border Leicesters, Lincolns, and Shropshire Downs were in goodly numbers and finely-bred. Mr. Bland invaded the northern metropolis with some of his finest specimens, and took some of the first prizes; but in Mr. Lealie, of Glasslough, he found a rival worthy of his mettle, and the latter did not let the former take *all* the first prizes. The pigs were excellent, but not numerous.

There is but time and space to give a general epitome of the live stock exhibited in the farmers' classes; there were of Shorthorn cows and heifers twenty of all ages, and so remarkably good as to call forth unbounded applause for their beauty, condition, cleanliness, and their evident productiveness as dairy stock. In Ayrshires they exhibited about 15, remarkable for their evident productiveness; but the finest feature of all was the splendid array which farmers made of cross-bred cattle, the beauty of their colours, their grand size, substantial proportions, and capacious udders riveting

the attention of the visitors to such a degree that we could scarcely get a peep at them. They numbered about thirty, and do infinite credit to the spirit and the knowledge displayed by the north men in the selection and crosses which were produced. In sheep they were equally successful, whether in Leicesters, Border Leicesters, or Shropshire Downs; but, like the amateur class, the pigs they exhibited, though remarkably good and well bred, were few, eight pens covering the whole of the farmers' entries. The show of poultry was a very fine one; and in butter there were about 23 samples in firkins, crocks, and samples of six prints of  $\frac{1}{2}$  lb. each. Of scutched flax three samples, and of green flax six samples, the finest was that of James Taylor and Sons, who got the first premium, being much over three feet long, Mr. Borthwick's, who got the second, being nearly as large, and of very superior quality. The show of implements and machines was a good one, but we missed some of the English and Scotch makers, who used to come and pick up some loose cash, but not without giving value for it; however, their places were well filled by their agents.—*Abridged from Irish Farmer's Gazette.*

## THE RUST-IN-WHEAT COMMISSION.

*To His Excellency Lieutenant-Colonel Hamley, Officer Administering the Government of South Australia, &c., &c., &c.*

His Excellency Sir Dominick Daly, Knight, late Governor-in-Chief of South Australia, having appointed us whose names are hereto appended a Commission to inquire into the diseases affecting the cereal crops of this province, we have the honour to report to your Excellency as follows:

I.—**PRELIMINARY.**—The natural history of the rust-disease having for years past formed a subject of scientific investigation, your commissioners did not anticipate being able, with the limited means and appliances at their command, to throw new light on the physiology of that malady; but they have directed their best attention to the question whether the disease which has recently destroyed our cereal crops was identical with the "rust" described by scientific men, or whether it was some new and modified disease, generated by peculiar conditions of soil and climate, affecting the growth of corn in this colony. They have, however, notwithstanding former researches, inquired anew whether the cause of rust was to be sought for in the seed sown, in the soil itself, or in atmospheric conditions affecting the growth of the plant; and, finally, whether any plan could be devised for mitigating the severity of the disease. On these points much valuable evidence, written and oral, has been collected, and will be found appended to this report. Your commissioners have also directed their attention to the disease popularly designated "take-all," and have recorded the observations of many experienced and competent witnesses. The method of investigation has been the following: A schedule of questions (see Appendix), comprehending some twenty separate branches of inquiry was printed, and parcels forwarded to all the corporations and district councils of the province for distribution amongst agriculturists and other suitable persons in their respective neighbourhoods. It was considered better that the various district councils should themselves select the farmers whose evidence was required, than that the commissioners should limit their inquiries to individuals of their own choice. As regards the schedule of questions itself, it was framed simply as a guide to those who might wish to avail themselves of it; each person addressed being invited to state his own views and opinions in his own way, altogether regardless of the questions proposed by the commissioners. Many witnesses have, in accordance with this invitation, given the result of their experience on various points of importance, supplementary to their replies to the schedules. The communications received in answer to the queries propounded by the commission have been carefully considered and collated, the most important portions of the information elicited being hereto appended. This has un-

avoidably occasioned some delay, but the value of the evidence thus secured will more than compensate for the loss of time. In addition to the useful and varied information gathered through the post from about 700 practical agriculturists, various witnesses have personally attended before the commission, and given *visu voce* evidence, which will also be found in the appendix. These witnesses include some of the most experienced and observant wheat-growers in the province, as also our ablest agricultural chemists and microscopists. Your commissioners have also had the benefit of a thoughtful and elaborate paper, prepared by Mr. Charles Todd, on the rainfall of last season, compared with that of seasons preceding—a paper to which they point with more than ordinary satisfaction, as replete with information valuable to the scientific farmer and the naturalist. Reference should also be made to a report kindly and readily furnished by Dr. Mueller, of the Melbourne Botanic Gardens, on the subject of the rust in wheat, summarizing the latest researches and discoveries with regard to that fearful malady, and effectually setting at rest some plausible but unsupported theories on the subject. The scientific aspects of the question have also been professionally elucidated by Drs. Muecke and Schomburgk, and Messrs. Francis, Cossins, and Ey, of this colony, whose conclusions are also appended. With these preliminary remarks, your commissioners proceed to submit the result of their investigations.

II.—**RED RUST.**—As regards the physiological character of red rust, there can be no doubt whatever that it is essentially a vegetable parasite or fungus, attacking the plant externally, and brought into active operation by certain atmospheric or climatic conditions, the most effective of which last year were heat and humidity. In September and October there was a most unusual amount of moisture combined with sultry heat, and frequent heavy dews at night—that blades of cereal plants being kept in a continual state of dampness, with occasional rapid evaporation, causing the pores of the leaf to be more than ordinarily open, and thus facilitating the entrance of the infinitely minute spores, or seeds of the rust fungus, which are more or less always floating in the atmosphere, or deposited on the soil or surrounding objects, ready for dissemination by every wind that blows. An opinion has been expressed before this commission that the rust on the wheat blade is simply an exudation from the plant itself, a spontaneous overflow of sap, and is not the result of parasitical attack. But this theory is altogether without support, either in the general conditions and circumstances of the rust as observed by the naked eye on a great variety of plants, or

in the microscopic appearances of the diseased wheat plant. For although the most luxuriant growths of wheat have doubtless suffered most from the rust, thus lending an apparent support to the theory of sap "exudation," it is an undeniable fact, that a large number of cereal plants and grasses—the very reverse of luxuriant—have also suffered from rust, which must, therefore, be accounted for in some other way than by the outflow of superabundant juices. The spores of the rust are proved to be true seeds, possessing a uniform and definite character according to their variety, retaining their vitality as other seeds do, and capable of being developed at any time by the application of heat and moisture. Your commissioners have examined through the microscope various specimens of last year's rusted wheat, and find the rust spores identical in appearance with those noticed and delineated by Mr. Cooke, and other eminent mycologists, who have written on the subject. There is, therefore, no doubt whatever, that the rust in wheat, now so painfully known to South Australian farmers, is identical with the disease long recognised by the same name in Europe, briefly described by Dr. Mueller, in his report hereto annexed. It has also been shown in evidence, that the red rust has affected, in addition to wheat and other cereals, flax, lucerne, wild oats, wild barley grass, reeds, and many other vegetable productions. It has been noticed that the red rust appeared in some localities before the humid weather of September and October, and also (in the south-east), after the dry, hot weather had set in. On this point it may be remarked that there are two distinct varieties of red rust, designated in Dr. Mueller's paper, *Puccinia graminis* and *Puccinia straminea*—one of which has the power of producing its spores in almost any season. Mr. Ey, in his evidence, also refers to the two kinds of rust, and avows his conviction that both have been active agents in the destruction of last season's crop. The rust that appeared earlier is popularly known as the "long corn" rust, and is believed to have borne a full share with the *Pera rubigo* (or true rust) in the desolation of our last harvest. In the course of this investigation some points of importance have been established, materially affecting and modifying opinions hitherto entertained. In 1866, it was reported by the Agricultural and Horticultural Society, who took evidence on the subject of red rust, that crops grown upon land long cultivated were much more liable to the disease than those grown upon new land, and that crops grown upon well cultivated and manured land were much less liable. These opinions, though disavowed by some cultivators, prevailed very generally down to the time when your Commissioners entered upon their investigation; but the experience of last season excited grave doubts on the subject; and the result of the evidence now adduced entirely sets aside this portion of the report of the Agricultural Society. It is found, as the almost uniform result of last year's operations, that rust has prevailed upon all kinds of land—upon lands long cropped, upon fallow lands, upon grazed lands, upon virgin soil, upon manured lands, upon the plains, and upon the hills. But more than this, it has been proved that in nearly every instance the richest lands have suffered the most from red rust, and that, in a large number of cases, the best crops have been reaped from the poorest natural soils, and from those most exhausted by frequent cropping. It is an almost universal fact that wherever the wheat grew most luxuriantly in September and October, there the failure has been most complete; whilst those crops that in the early part of the season were the least promising, as a rule, turned out by far the best sample and the heaviest yield. This very remarkable circumstance, attested by hundreds of witnesses, is thus accounted for: Luxuriance in vegetation, like excessive fat in animals, is not identical with vigour. Plants forced into abnormal luxuriance are more susceptible of climatic changes than those which are tough and hardy. The more juicy and succulent the plant, the more predisposed is it to the irruptions of the rust. The pores of the leaf being unusually open, the minute spores of parasitical fungi can more readily enter. Then, again, the more dense and heavy the crop, the less possible is it for the wind to circulate, and the saturated leaves to dry. On the other hand, in a thin, light crop, the leaf pores being less open to the entrance of the rust seed, the disease is not so freely propagated, whilst the whole crop is far better situated to enjoy the drying influence of the wind, which retard the development of the parasite. The poor crop has thus a twofold advantage over

the thick and luxuriant crop in a season favourable for the development of rust. Hence, so far as red rust is concerned, rich soils, and what is termed "high farming," instead of shutting out the disease or mitigating its severity, operate in the contrary direction, always supposing that the climatic conditions favourable to the development of rust are present.

The *modus operandi* of the disease is twofold. The rust spores, obtaining entrance through the open stomata, or breathing pores of the plant, are very quickly developed, and, pushing forward rootlets (*mycelia*), gradually work their way along the sap vessels of the leaf—in all probability injuring, by their multiplication and progress, its internal mechanical structure. But the chief damage—or, at all events, that which can with most certainty be traced—is caused by the absorption of the wheat sap by the parasite that has entered its channels. The juices that should have gone to nourish the wheat-ear are intercepted in their progress by the rust fungus, which starves the grain by living on its proper nourishment. This is not only deduced from microscopic observations, but is clearly demonstrated by chemical analysis. Healthy grains of wheat contain certain definite proportions of inorganic ash—the ash, in its turn, containing definite proportions of phosphoric acid, potash and soda, and magnesia. It has been demonstrated that rusted wheat is very deficient in that ash, having sometimes less than one-third its proper quantity. On the other hand, the rust spores, gathered from the rusty wheat, yield, on analysis, an extraordinary quantity of ash; and this ash is found to contain a large amount of the constituents present in the ash of healthy wheat, but wanting in the ash of rusty wheat. Doubtless further experiments on this point are eminently desirable; but, as far as chemical analysis has extended, it seems fairly proved that the wheat perishes through the absorption of its proper nutriment by the rust fungus, and that the constituent elements wanting in the shrivelled grain are to be found in the parasite which has fed upon and destroyed it.

III.—SEED WHEAT.—Your Commissioners having come to the conclusion that the red rust is not originated in the soil, next directed attention to the several varieties of seed-wheat, with a view to determine whether any descriptions were of more hardy character than others, and better calculated to repel the attacks of the disease. On this subject the evidence of the numerous witnesses is remarkably coincident. With but very few exceptions it has been found in all parts of the colony that the Tuscan and purple straw varieties suffered least, whilst the more prolific varieties, such as the Goldsmith, suffered most. The Tuscan however, being a poor, yielding grain, is not likely to be generally selected for seed; and the purple straw, therefore, is the wheat now generally recommended as combining a fair yield and a certain degree of resistance to the red rust. It of course remains for the farmer to determine whether (to ensure the weightiest crop) he will sow prolific but tender varieties; or whether he will purchase a certain degree of immunity against the rust by being content with a variety of seed not quite so famed for heavy bearing. It is noticeable that the Victorian Commission of 1866 emphatically recommended care in the selection of seed wheat, reporting favourably of the red straw and Tuscan, and deprecating the golden drop, white prolific, white velvet, and Winslow. Attention has been specially directed during this investigation to the question of the fitness or unfitness of shrivelled grain, and grain from rusted crops, for seed. There being in many districts of the colony but little good seed this year, your Commissioners deemed the point now under consideration to be one of the utmost importance, and they have much satisfaction in stating that numerous witnesses declare, as the result of their own personal experience, that shrivelled and rusty seed will produce healthy and abundant crops. This fact has, indeed, been known both to scientific observers and practical farmers for many years, and is specially remarked upon by the Victoria Committee. In that colony scientific research and practical testimony were both brought to bear on the subject; and, although Dr. Mueller and his colleagues appear somewhat hesitant to account for the fact, yet they are most confident in reporting that not only will shrivelled and rusty seed produce good plants, but in many instances have yielded healthier and heavier crops than those raised from first-class seed. Nevertheless, as strong objections had been urged against the use of last season's rusted wheat as seed, the Commission felt it desirable to bestow special care upon this

branch of their inquiry. They therefore collected all the reliable information in their power, and also requested Dr. Schomburgk, of the Botanic Gardens, to experiment upon various samples, including some of the worst procurable. The result of experiments thus made fully supports the evidence of agricultural witnesses. The very thinnest grain germinated as readily as the finest; and, although on first springing up it appeared slightly weaker than the other, it grew freely, and in a few days was as vigorous as that proceeding from a plumper seed. As however the germ must be nourished from the substance of the seed until its roots can draw nutriment from the soil, it is reasonable to suppose that very poor seed would have a better chance in good than in exhausted soils. Your Commissioners therefore consider that their inquiries on this particular question terminated alike in an undeniable and satisfactory conclusion. Much valuable information on that subject, including Dr. Schomburgk's report, is appended. It having been thought by some persons that the rust may partly be accounted for by the continued use for many years of the progeny of the same crop, and that a change of seed, brought from distant localities, would shut out the disease, your Commissioners report that this idea is not supported by the evidence. On the contrary, crops raised from seed brought from distant places have been affected with rust equally with those raised from seed grown on the same sections. No doubt, for other reasons unconnected with rust, change of seed is often desirable; and the evidence of witnesses on this point shows that new seed should be procured as nearly as possible from a latitude similar to that where it is intended to plant it, and also from a poorer soil to a richer one, and *vice versa*, otherwise time will be lost in the acclimatization of the new arrival. Fine specimens of South Australian seed-wheat have produced soft and diseased crops in England, in fields where seed grown in the same neighbourhood produced healthy and fruitful plants. The colonial seed had not become acclimatized, and the plant suffered accordingly. But although the red rust is shown to be dependent upon atmospheric conditions, and to commence its ravages upon the stem and leaf of the plant, and not to ascend from the root, it is nevertheless desirable to pickle the seed for the purpose not only of killing the spores of black rust or smut, but also in order to destroy spores of the red rust which may happen to attach to it. On the subject of the composition of pickles for wheat, a few words will presently be added.

**IV.—BLACK RUST AND SMUT.**—Smut being effectually destroyed by a proper preparation of the seed, it has not been thought necessary to inquire particularly into a disease within the knowledge of all practical farmers. With reference to black rust, late sowing is recommended as a preventive, unless the ground should previously be thoroughly saturated. Dry ploughing, by turning up the land in clods, and leaving open cavities beneath the surface, which harrowing does not fill up, is considered by several practical agriculturists as strongly favouring the development of black rust. One witness says, "The remedy I always adopt is, never to work my land unless it is sufficiently saturated with a certain depth of rainfall, so that the soil is sufficiently moist throughout, and then working the land when it is mellow. I have always found I have avoided black rust. I was led to conclude that black rust came from the roughly-broken state of the soil; as the harrows only penetrate an inch or two—the black rust always made its appearance when the roots got down that far—the bottom being hollow as a honeycomb." Others, in like manner, recommend the thorough working and pulverization of the land, combined with proper pickling, as a sufficient antidote to this form of cereal disease.

**V.—TAKEALL.**—This disease, so destructive in many districts of South Australia, is not so well understood as rust. Farmers and chemists are alike at sea—ploughmen and microscopical observers differ in *lofo* as to its nature and causes. It is said to result from an exhausted soil, from the presence of too much salt in the soil, from the deficiency of some constituent element essential to the maturing of cereal crops. It is declared to be want of drainage, and it is said to be want of measure. It is affirmed to be caused by a vegetable fungus, and to be a disease analogous to the potato disease. It is also said to be the result of insect ravages. Scarcely any two witnesses agree on this point, whether farmer or chemist. But the subject is of far too great moment to be passed over indifferently. In some respects, takeall is more to be dreaded

than red rust. The latter cannot commit wholesale destruction, unless in connection with a description of weather such as we rarely have in this colony; but takeall appears altogether independently of the weather. And as its ravages are irrespective of climatic influences, so are its movements inexplicable by reference to locality or soil. It is, like last season's rust, to be found everywhere, and the richest soils often suffer the most. It attacks newly-broken or fallowed land as well as land frequently cropped. It especially attacks the slopes of hills—not so often the table land on the top, nor the flats in the valley, as the slopes and sides. All cereals fall before it; even native grasses disappear. It works in patches, selecting certain spots or centres—thence radiating, often succeeded by cockscur or Grant's thistle, the takeall in following seasons reappearing in other spots. Its movements being so little reducible to rule, experience and observation are at fault in endeavouring to explain it, and hence conflicting ideas. This difference perplexes the inquiry, whilst the rapid spread of the pest, and the fear that it will every year encroach upon wider tracts of country, render close observation and study a duty of the utmost importance. The appearance of the cereal, above ground, as it fades away and perishes under the influence of this insidious invader, needs no description, being but too well known. The root has been examined, and appearances detected, leading some observers to conclude that the disease is caused by a vegetable, and others by an animal parasite. Dr. Muecke has magnified and photographed fibres of the roots of wheat plants suffering from takeall, exhibiting a number of minute white threads of a woolly appearance, which he considers to be the *mycelia* of a fungus causing the disease. Mr. Ey, who has also examined it microscopically, says that it is not a fungus, and that the supposed fungoid may be found attached to all roots, healthy or unhealthy. He considers that the disease is caused either by animalcula attacking the plant in the first instance, or by the growth of a sort of a lichen at the bottom of the stalk, which serves as a nest for animalcula. He says: "What I recognise under the name 'takeall,' is the *Fibrio tritici*, or eel of wheat. A plant taken from a diseased spot will be found black on the stem, from the roots to the first internode; and on pressing, a thin film of lichen or moss will come off. In this will be found a number of animalcula coiled up, apparently dead; but on being moistened with a drop of water, on a glass slide under the microscope, will come to life in an hour, moving about with great rapidity. They are like eels of wheat, which, as yet, have only been found in the grain. I have not yet satisfied myself whether the eel or the lichen is the primary cause; but one of the two is takeall. The animalcules might be sown with the seed; it is sometimes the case that one grain of wheat will contain 4,000 to 5,000 eels of wheat."

The witnesses, however, whilst giving expression to their opinions, or their conjectures, were all (with the exception of Dr. Muecke, who strongly adheres to the fungoid organ of takeall) very careful to avoid any final or positive avowal. It is scarcely probable that the takeall results from the development of *vibriones* sown in the seed wheat, because the disease has been just as bad in crops from seed pickled in strong dilutions of sulphuric acid and other mixtures fatal to insect life, as in crops not pickled at all. The Victorian Committee make no reference to takeall—the very name in fact being an admission that the nature and cause of the malady are not as yet found out. The use of sulphur has been found beneficial, and land rendered barren by takeall has been recovered where the ashes of a bush fence had been scattered; but it is doubtful whether the sulphur acted specifically upon the supposed spore or egg of the takeall, or chemically upon the soil, nor is it certain whether the ashes of the bush fence destroyed the takeall by acting chemically upon the soil, or whether the change noticed where the edge was consumed might be attributable to the heat of the fire. It is exceedingly desirable that this most vital question should be thoroughly sifted, as there is imminent danger of our wheat lands succumbing section by section to this mysterious visitor, and the Commission are, therefore, of opinion that a series of experiments in the application of diluted sulphuric acid, and also of sulphur in its various combinations, both as a pickle for the seed and as a top dressing for the diseased spots in the land, might be of great use, inasmuch as the only generally available remedies for takeall described in the evidence as having been successfully used are

diluted sulphuric acid, applied by Mr. Ey as a top dressing, and sulphur and lime, used by Mr. Martin as a pickle for the seed.

**VI.—PICKLING SEED WHEAT.**—Although experience shows that pickling seed wheat is no security against red rust, it does not follow that it has no effect at all upon that disease. Apart, however, from this formidable enemy to cereals there are other foes to be met and vanquished only by a proper system of pickling the seed, and hence the inquiries made and evidence taken by the Commission on the subject. It is not necessary to dwell upon a practice so well known and generally observed; but it may be remarked that the evidence taken discloses great difference of usage in this particular. Whilst some farmers only let their wheat remain in pickle for a few minutes; others allow it to be in solution for hours. The chemical witnesses recommend six or eight hours' steeping; Dr. Muecke says eight if the weather be wet, and twelve if it be dry, giving four ounces of bluestone to the bushel. Some farmers do not soak the wheat at all; but merely sprinkle it with the liquid solution, turn the heap over a few times, and dust it with dry lime. It is doubtful, however, whether the fungus spores adhering to the grain are effectually destroyed in this manner, and as the power of wheat to retain its vitality under certain conditions of pickling can easily be ascertained by experiments, it would be worth while for agriculturists to make a set of trials. There is much reason to fear that in many instances, from the weakness of the solution and the insufficient time allowed for the grain to absorb it, the operation is null and void, so far as regards the destruction of the parasitical spores. It has been shown that sulphur, either in form of flowers, or milk of sulphur, or in that of sulphuric acid, has been employed with very excellent effect. The sulphuric acid is used, four ounces, by weight, to each bushel of seed, diluted with as much water as the wheat will take up; the latter, after a few hours' solution, being dried with slaked lime. Sulphur and lime also make an excellent combination most effectual in destroying fungi. The milk, or flowers of sulphur, in powder, to be mixed with twice its weight of fresh slacked hot lime, ten gallons of water to each pound of sulphur: this forms a sulphuret of lime with which the wheat is to be well moistened, and afterwards dried with fresh slacked lime. It is to be hoped that a few practical experiments will be made during next seed-time, with a view to determine the double question of the proper strength of pickle and the length of time that the seed should lie in it.

**VII.—STUBBLE BURNING.**—On the subject of stubble burning, in connection with the rust disease, the evidence is conflicting. From the prevalence of the rust last season it follows, however, as a matter of course, that the country is covered with rust spores to a far greater extent than usual, and that a large proportion of them adhere to the straw and stubble that lie on the stubble lands. These spores would necessarily be destroyed by the burning of the stubble, although enough would still remain in other places to spread the disease next year, should we have a return of last season's weather—a contingency, however, which, to judge from the past, is highly improbable. Still, as we have had rust in several previous years, although to nothing like so fearful an extent, the Commission recommend the burning of stubble, and the collection and burning of hedge clippings and other refuse matter, in which the seeds of the rust fungus will have found shelter.

**VIII.—EXHAUSTION OF THE SOIL.**—Although not immediately connected with red rust, your commissioners have taken evidence with reference to the constituent elements of the soil in this province, and have to report that this important branch of agricultural science has been almost wholly neglected. Not more than half-a-dozen analyses of the soil appear to have been as yet made, so that science has so far lent practically no aid at all in instructing South Australian farmers as to the adaptation of their lands to the growth of particular crops. It is, in the opinion of this commission, highly desirable that an agricultural chemist and analyst be appointed, in order to carry on a regular and continuous system of experiments upon soils and manures, and also to conduct microscopical and chemical observations bearing on the subject of the growth and disease of our cereals. The vast tract of country annually cropped with wheat is being gradually robbed of its phosphates, and other constituents essential to the formation of a healthy growth; and as there is

scarcely anything returned in the shape of manure, the grain-producing power of the soil is every year becoming less, involving a sure diminution of average yield, even though we may escape the plague of red rust. The appointment of an official agricultural chemist would not involve any serious expenditure, whilst it would afford to farmers generally the means of obtaining reliable analyses of their wheat-lands at a nominal charge, thus guiding them in the choice of crops, and in the adoption of measures calculated to restore to the soil those fertilizing elements of which it may stand in need. It cannot be too constantly borne in mind that soils are not always to be correctly judged from appearance, even by the most practised eye. Land that appears rich, and which, as regards most of its constituents, may really be so, may, notwithstanding, be deficient in some one element indispensable to the growth of a vigorous crop, or of some one element necessary to render the other constituents of the soil soluble and capable of assimilation by the plants. This knowledge can only be acquired by chemical experiment. In other countries, and in the sister-colony, especial attention is devoted to this branch of agricultural science which, though pre-eminently necessary in South Australia, is neglected with an indifference as reprehensible as it is unaccountable.

**IX.—CONCLUSION.**—On the whole, and especially as regards the red rust, your commissioners, though, necessarily unable to discover a specific remedy for a disease, the germs of which are universally diffused and brought into active vitality by atmospheric causes, have much pleasure in submitting to your Excellency the large amount of valuable information elicited by this inquiry. If a positive cure is not discovered, several very serious mistakes are corrected; mistakes which would be costly in their operation and disappointing in their results. It is shown that the extraordinary ravages of red rust last season were not caused, as many asserted, by exhaustion of the soil; and that, therefore, expensive manurings—however beneficial in other respects—are useless as a preventive of rust. It is shown that there are some wheats harder than others; the farmer thus having, in some small degree, the means within his own power of diminishing the extreme destructiveness of the disease by avoiding those varieties that are most easily overcome by it. It is also shown that as red rust is not propagated, like smut, from diseased seed, shrivelled grain, of little value for milling purposes, will produce both healthy and abundant crops, under ordinary favourable circumstances of soil and climate. It is shown that agricultural chemistry has scarcely made a start as yet in this colony, although of so much importance to a proper system of cultivation. And finally, your commissioners hope that the attention which has been so widely directed in all parts of the provinces, not only to the sad visitation which has befallen it, but to the general condition and prospects of agriculture, will have the effect of leading to closer habits of observation, and to more careful experiments on the part of farmers themselves; and on the part of the Legislature and Government, to a corresponding appreciation of the claims and requirements of an interest which, without exaggeration, may be represented as the cardinal industry of the province, and the chief foundation of its prosperity.

Committee-room, Parliament House, April 9th, 1868.

JOHN H. BARROW, Chairman.  
THOS. HOGARTH.  
WM. EVERARD.  
JNO. CAER.  
W. CAVENAGH.

[The Appendix referred to in this Report has not yet been published.]

**CURE FOR RED-WATER.**—Boil 6 lbs. of nettles in a gallon of water until it is reduced to half a gallon. To three pints of this juice add one pint of salt, and give it to the animal when she is attacked. If given in the early stage, one dose is sufficient; if the attack has been in the animal for some time, a second dose will effect a cure. [The person who gave us the recipe milked 60 cows, and he never had a fatal case since he was told this remedy.—ED.]

## THE CONDITION OF THE AGRICULTURAL LABOURER.

Mr. BAILEY DENTON read a paper on this subject at the meeting of the Society of Arts, in which he said: At the next general election that class of the community known as the agricultural labourer will be the only operative class which will be excluded from voting. Though, in the practical view I take of the matter, I fail to discover any reason why operatives living in boroughs should be admitted to the franchise, while operatives living in the country should be excluded, I cannot help recognising in the uneducated, dependent, and scattered condition of the latter the real reason why the country has tacitly allowed—as if by common consent—a distinction to be made between the wage-paid labourer of the factory and the wage-paid labourer of the farm. This distinction cannot have arisen because the premises occupied by the one are more valuable than those occupied by the other, for it would be difficult to say which labourer's dwelling—the rural or the urban—costs more money to provide, and it has often been shown in this room that the actual money-rent paid by the farm-labourer is no criterion of the value of the premises he occupies; nor can it be because the wages of the one are much greater than those of the other, for when the earnings of each are carefully dissected it will be seen that there does not exist that great difference between the two which there is generally supposed to be. It can, in fact, only arise from those causes which limit his mental abilities, and prevent his increasing the value of his labour, while they depress his status in the social scale—causes which it is the duty of the country to investigate and remedy. But before I go into these causes and remedies, I will do my best to remove the misapprehensions that prevail as to the value of the farm-labourer's occupation and the amount of wages his services command. There is much in the one that affects the other, and no effort to improve either can be successful unless we carefully comprehend the circumstances of both. The average rent of farm-labourers' cottages at the present moment may be fairly stated to be rather under than over 1s. 6d. per week, which is less than £4 a-year. This rent is quite as much as the majority of old existing cottages are worth, for most of them have but one bed-room, and are wanting in those accommodations which are essential to decency and comfort. Such dwellings have been, and may still be, built for about £50 each, if constructed of plaster and thatch, without regard to substantiality, and £4 a-year—being 8 per cent.—may be considered a full return, if such dwellings are admissible at all. But if we have reference to those cottages which, under the influence of sanitary reform and sound estate economy, are taking the place of those miserable hovels—which all well-thinking people condemn—we shall find that their average cost is £180 each, or £320 the pair, exclusive of the site on which they stand. This site, which would cost £15 more, would make the fee simple value of the whole £175. We all know that every speculator, employing capital in house building, looks for something like 7 per cent. if he is to replace the capital and make 5 per cent. net after paying insurance and doing repairs. If, therefore, a farm labourer paid for his occupation the rent in money which a speculator would demand, the payment, instead of 1s. 6d. or 2s., which he still continues to pay for a good cottage as he did for a bad one, would be £12 5s., which closely approximates the rateable value fixed as the qualification of a county voter, while it exceeds that of the lodger in boroughs. But it is not in money wholly that the farm labourer pays for the improved cottage, if it forms part of the farm on which he works, or is so connected with it that the farmer has command of the services of the cottager. A farmer having good cottages at his disposal can select the best workmen as his daily labourers. Moreover, he can keep them, which is not the case with the occupiers of the miserable hovels that generally exist; and as newly-built cottages are now usually placed so as to reduce to a minimum the distance the labourer has to walk, whereby time and sinew are saved, the advantages to the employer are, in the aggregate, equal to the difference between the return due to the condemned hovel and that due to the improved cottage; and thus, in point of fact, the farm labourer receives

in a better home an equivalent to increased wages. Having had some considerable experience in nearly every county in England, I desire to state shortly the conviction at which I have arrived—that, measured by the real value of the services rendered by the agricultural labourers in different parts of England, the prices peculiar to different districts are as high as the return to be gained from those services will sanction. It appears to me to be a fallacy to suppose that the labourers of one district are as good workmen as the labourers of another, and that for the services of each, when applied to the same object, the same money should be paid. Still, it can only be on such grounds that the proposal lately enunciated for the formation of unions, even though "established on principles strictly defensive," among agricultural workmen, can be supported. Considering that combinations of workmen are injurious in proportion as ignorance prevails, and that the want of education is the special characteristic of the agricultural labourer, I can anticipate only the worst results from unions among them, and am quite at a loss to comprehend how any national benefit can arise by encouraging them. If the labourer of Dorsetshire or Devonshire was as able a workman as the labourer of Northumberland or Lincolnshire, a common standard of daily wages could be adopted; but the truth is that there is as much difference in the value of ordinary labour in different districts in England as there is in the character of labour in different countries abroad, and it is only consistent with economy that this difference should govern the price paid. In making this remark, however, I do not lose sight of the fact that the price of labour must be regulated in some degree by the cost of maintaining labourers and their families in their own districts, so as to perpetuate the race upon which the produce of the land depends. With respect to the wages of the farm-labourer it has been my duty for the last seventeen years to inquire into the standing wages of every locality in which drainage works have been executed. In addition to these inquiries, I have recently made others, and have obtained such reliable information, that I believe I am perfectly justified in stating that the present average weekly wages of the farm-labourer, excluding extra allowances at hay-time and harvest, and all payments for piece-work and over-time, as well as the value of various perquisites in the shape of beer, milk, fuel, &c., are as follows:—

	s.	d.
North-Eastern district ... ..	14	6
North-Western district ... ..	14	0
Mid-Eastern district ... ..	13	0
Mid-Western district ... ..	11	0
Midland district (exclusive of Middlesex) ...	10	9
South-Eastern district ... ..	12	0
Mid-Southern and South-Western districts ...	10	6

These figures include shepherds and horse-keepers, but do not include the wages of bailiffs, where they exist, nor of other special employes, nor the earnings of labourers' wives and children. They include, however, beer and cider when they form a regular daily allowance in lieu of money, but not otherwise. The mean weekly day-labour wages of able-bodied men throughout the whole of England may be taken at 12s. 6d. To this must be added the additional gains by occasional piece-work,\* extra payments at hay-time and harvest, when double the ordinary wages is frequently given, inde-

\* The advantages gained by the adoption of piece-work in the place of day-labour are stated by one of our leading farmers, Mr. Charles Howard, of Biddenham, to be—1. The work is done more expeditiously, at the proper time and with less supervision on the part of the employer; 2. It is less expensive than day-work, and payment is made for only the work done; 3. The labourer, finding his wage is regulated by the quantity and quality of the work performed, is more industrious, and exercises more skill in what he does; and 4. By placing higher wages within reach, the temptation to leave farm-work or other occupations is lessened.

pendently of the increased allowance of beer or cider. In the aggregate, the actual income derived from these employments is equal to from 1s. 6d. to 3s. a week, according to the custom of different districts. Where piece-work can wholly take the place of day-labour, a labourer may earn 25 per cent. more than by the day. The total value of the beer and cider supplied to each labourer as his allowance, at hay-time and harvest, when employed in drilling and machine-threshing, and when engaged in piece-work, if spread over the whole year, would amount to from 1s. to 2s. a week, according to locality. With these additions to his direct money-wages, the farm-labourer gains from 15s. to 16s. per week, taking the mean of England. But, besides this aggregate, he gets other advantages, which are unknown to the industrial-labourer living in a town. The rents of the dwellings of town-operatives vary from 4s. to 6s. a week, some having very good dwellings for these rents, while others are obliged to pay as much for lodgings only. Comparing these figures with the 1s. 6d. or 2s. paid by the agricultural-labourer for cottages equally as good or better than the dwellings of the town-operative, the difference must be regarded as a gain to the former. The town-operative seldom, if ever, has the advantage of a garden wherein he may grow potatoes and vegetables. His outlay for these essential articles of food is often great, particularly if he has many children to provide for. In fact, the ordinary payment for potatoes and vegetables by a mechanic, with a wife and three children, living in town, is stated to be 2s. 6d. a week. An agricultural-labourer, if he is fortunate enough to have—what he ought invariably to have—a rood of garden-ground as part of his occupation, which he may cultivate after he has done his wage-paid work, will grow upon it vegetables sufficient to yield him a return, after payment of rent and for seed, of at least £4 a year, which is rather more than 1s. 6d. per week. I am assuming in this estimate that he has time and strength sufficient to do all the labour that is required to cultivate it, and that he is careful in storing the refuse of his dwelling, i.e., the ashes, sewage, and waste, so that he may avoid any payment for either labour or manure. Thus it will be seen that from his house and garden the agricultural labourer gains advantages equal to at least 4s. a week, which, if added to his money returns, will raise his wages from 15s. or 16s. to 19s. or 20s. a-week, independent of what his wife and children may make, and this frequently adds 25 per cent. to his income. I have said nothing about the gains of gleanings, which have been estimated at £1 1s. 10d. to £2; nor about the favourable difference in the cost of bread, meat, and milk in the country compared with what it is in towns; nor of the benefit an agricultural labourer is said to derive from the keeping of a pig, as I am doubtful myself whether anything is fairly gained by it; neither have I estimated the great advantage of pure country air in securing the health and strength of the labourer and his family, though all these have a money value which should be considered. I may here state that for several years past I have adopted the weekly wage of 90s. as the basis of payment to the able-bodied labourers employed by the General Land Drainage Company when away from their homes during the draining season, at which time the number has frequently exceeded 1,500. The system adopted when going into fresh districts is to make the earnings of a few good practised hands, of medium capability, who follow the company's foremen wherever they go, the data for paying all other hands. The weekly work of a good gang of drainers will, if divided, give to each hand as much as from 30 to 40 rods of digging, and the price per rod will be fixed by the foreman at such an amount as to apportion to the standard men 10s. to 22s. a-week, according to the length of the day, after paying for the repair of tools. While these figures are the wages of standard workmen, the local labourers, at the commencement of the work, will seldom earn more than from 10s. to 12s. Of course this is to be expected, and the statement is only apposite to the present inquiry, when it is said that, whenever a turn-out or a strike takes place it is invariably found to have its origin in the local men, and there are many kindly-disposed persons who take their part, though the result invariably shows, if they will only persevere, they can, after a time, make as good wages as the older standard hands. With this knowledge it will be understood with what dismay I look upon the proposal of unions which can only maintain inferior work, done at an extravagant cost, and discontent at the same time. The weekly earnings of different

labourers, which fairly represent the class known as industrial operatives, may be stated to be as follows:—

Carpenters and joiners .....	from 18s. Od. to 28s. Od.
Sawyers .....	" 21s. Od. to 26s. Od.
Bricklayers .....	average 31s. 6d.
labourers .....	19s. 6d.
Brickmakers .....	from 24s. Od. to 30s. Od.
Masons .....	average 30s. Od.
labourers .....	17s. 6d.
Gardeners (exclusive of head gardeners) ..	16s. Od.
Smiths .....	from 26s. Od. to 28s. Od.
Painters .....	average 28s. Od.
Boot-makers .....	from 21s. Od. to 26s. Od.
Tallow workers (labourers) .....	average 18s. Od.
Coal miners .....	from 17s. Od. to 27s. Od.
Quarry men (slate) .....	" 18s. Od. to 23s. Od.
Carters .....	" 17s. to 19s. Od.
Railway labourers (maintenance) ..	" 15s. Od. to 20s. Od.
Butchers' men .....	" 16s. Od. to 18s. Od.
Police-constables .....	average 20s. Od.
Bakers' men .....	from 21s. Od. to 26s. Od.
Cotton workers .....	average 18s. 6d.
Silk workers .....	from 17s. to 24s.

The difference between these figures, which, it will be seen, do not cover the highest grade of trade operatives, and the wages of the agricultural labourer, is too great to exist between the two main branches of the wage-paid classes without making efforts to reduce it. It accounts for the fact that the population of our leading agricultural counties is decreasing, while that of other counties in which manufacturing towns exist is increasing with more than ordinary rapidity. It accounts, too, for the deplorable truth, that while the industrial labourers of our towns are known to save money to provide for incapacity and old age, the utmost the agricultural labourer manages to do is by means of provident societies, if he is lucky enough to belong to one which is well managed, to provide for illness during his working age. In the breast of the former there exists a hope of accumulating money, and ultimately becoming a master, while the final prospect of the latter is, I regret to say it, nothing but pauperism and the union. Sad as this picture is, it is a satisfaction to know that the rate of agricultural wages throughout the country has increased within these last 35 years quite as much as 20 per cent., while the prices of those provisions and supplies which constitute the ordinary food and necessities of life have, on the whole, decreased in the aggregate about ten per cent. The price of meat and cheese has increased within the last few years at an extraordinary rate. This is partly to be accounted for by the prevalence of diseases amongst cattle; and it is a curious fact that just 50 years ago the price of the best meat was the same as at this moment, though if we only go back half that time—25 years—it was about 40 per cent. cheaper. Inferior meat has not been liable to such changes, though there has been a rise of 2d. per pound. Bread, though high in price at this moment, remains at much the same cost as it was before the repeal of the corn-laws. Beer, though nominally cheaper, is so much worse in quality that we cannot regard it as actually reduced in cost. Tea, coffee, sugar and groceries generally are 50 per cent. less than they were 50 years ago. Clothes and shoes are equally cheaper. The cost of fuel, on the whole, is less than it was 35 years ago. Though I hope I have shown that the position of the agricultural labourer is not so bad as many represent it to be, no one can say that it is quite satisfactory; but with the profits of farming as low and uncertain as they are, it will be acknowledged that the only way to justify an increase of labourers' wages will be by rendering the value of the labour given greater than it now is. Active hands, directed by superior intelligence, already obtain wages above the mean of 16s.; and as there is greater scope in agriculture for the exercise of judgment than perhaps in any other trade or pursuit, in which physical labour forms so great an element, owing to the diversity of its objects and the casualties which may affect them, there is no reason to doubt but that with an increase of knowledge on those points which alone can enhance the value of labour, the earnings of the whole class may be increased. This directly brings us to the subject of education and its influence on the agricultural labourer by bringing his mind to bear on his physical duties. The state of education among agricultural labourers was truly

indicated by the Royal Commissioners appointed in 1861, to inquire into the state of public education in England, when they said that in the British army, which I believe is chiefly made up out of the agricultural class, "out of 10,000 soldiers examined in 1866, more than one-fourth could not write, and more than one-fifth could not read, while in the British Foreign Legion, raised in 1855, four-fifths of the Italians and 97 per cent. of the Germans could both read and write." Those, however, who are brought often into contact with the English farm labourer, as I happen to be, require no statistics to prove the almost total absence of education that exists among them. We can only wonder that with a nation so advanced in civilization as our own, such a condition of mind should be allowed to lower one particular class without a general effort on the part of all other classes to improve it. But the want of education is not to be wholly attributed to national apathy and indifference. It is due to various causes special to rural life, but perhaps the most powerful of all is the belief that existed largely at one time, and still lingers with some few farmers, that education disqualifies a labourer for manual work in the field. This belief had its origin in the little education possessed by the majority of farmers in times past, though at the present time there is no class more quickly awakening from indifference to the benefits of knowledge than the farmers. Moreover, they are not as a class to be blamed wholly for past indifference, for there were many landowners who themselves preferred men as tenants on their estates who were not possessed of those attainments which qualified them to appreciate education in their labourers. Not many years back it was a common thing to exhibit less care for the comfort of the labourer than for the comfort of cattle; better buildings, indeed, were provided for the cows than for the labourers. But this state of things is happily gone by. I will not here dilate on the manner in which the children of the labourer should be taught at school, nor enter upon the arguments for and against compulsory education. I am content to express my conviction that primary education at school—consisting of reading, writing, and arithmetic—is essential as the basis of improved practical knowledge, even though it be called forth in the duties of a labourer, and that, as public attention has at last been aroused to the object, the good sense of the country will rightly determine how it shall be attained. To confine our efforts, however, to elementary school learning would, I contend, fail in the object we all desire—which is, to see the farm labourer earning more money by labour of greater value to his employer. To do this, technical—that is, practical—education must be associated with primary school teaching. Technical education, I believe, has been more than once explained in this room to mean practical tuition in those operations which men are called on to perform in the business of life. It is, however, a term that has been exclusively used in connexion with the arts and sciences, and those businesses in which mechanical and chemical science have been mixed up. In agriculture I believe the term has never been used; but perhaps in no calling is technical education—if by that term we properly express practical education—more required. I will endeavour to make this understood. There is not a farmer in the country who, be he engaged in sheep farming or in dairying, in tillage, or in mixed farming, does not know the superior value of a labourer well acquainted with special duties. Take, for instance, a shepherd. The wage of a good shepherd is 16s. a-week, besides perquisites; and I venture to say that, at this moment, there is hardly any other description of agricultural service in which there are fewer capable men. A good shepherd is one of the most difficult men to obtain, and the loss to individual farmers, and to the country generally, from the want of them is very great. Again: Good horse-keepers are almost as difficult to obtain as good shepherds. From my own experience I can say that the difference between a good horse-keeper and a bad one is not to be measured by the simple difference between scanty and liberal wages. Any one accustomed to horses knows immediately, by the appearance or the touch of their skin, whether the man in charge of them knows his business; and he will confirm my opinion that any difference in wages will be more than counterbalanced by the saving in the corn which horses will consume, and the service obtained from them when well attended to, compared with that when they have been indifferently treated. The same remark will apply to the tending of neat stock. Speaking again from my own experience, I

have found that cattle under the charge of a man who thoroughly understands them will fatten quicker, and in every respect do much better with less food, than under a man who, from attempting indiscriminately all the duties of the farm, is master of none. In the minor matter of poultry, I have known many pounds lost by the want of proper treatment of them; and many a labourer's wife with a small plot of ground, who has brought intelligence to bear, has raised more poultry in a year than has been produced from a farm of several hundred acres. If this be admitted to be the case with live stock, it will be unnecessary for me to point out the advantages of employing men in the use of implements who have taken pains to understand them. The loss sustained by farmers from the careless treatment of costly implements is great. Few labourers know how to adjust them if they get out of order, and one who thoroughly understands the steam-engine so as to take charge of it when ploughing land or thrashing corn is indeed a prodigy in his parish. And why should we dread the purchase and use of steam-engines on our farms, on the ground that we have not a labourer who could take care of them, when tuition in youth would supply the omission? It is true that my friend, Mr. Howard, of Bedford, now and then undertakes to tutor a farm-labourer in the management of the engine, if he is previously assured of his intelligence. This circumstance, while it shows how an individual difficulty may be overcome, must go some way to prove that technical education is to be attained in the lowest grade of agriculturists, as in the more refined artisan class. It would be tedious to pass through all the branches of a farmer's business, to show how technical knowledge in the labourer would apply. There is hardly an operation in tillage that would not be done better, if the operator had early understood it. Take the simple operations of ploughing, drilling, and sowing: is not a good workman worth 1s. or 2s. more per week than a bad one? The same observation applies to hedging, ditching, draining, and thatching, in which there is no comparison between an expert man and an unpractised one. I have myself sent miles for a good thatcher or hedger. How, then, are these practices to be taught in youth? I will do my best to explain. The only reasonable ground for keeping the children of an agricultural labourer from school, is the circumstance that, having hungry stomachs to fill, and active bodies to clothe, they must earn something to pay for the food they eat, and the clothes they wear; and so weighty is this excuse with some men of high position and character, that they are led to doubt the policy of compelling attendance, even for the limited number of hours yearly which it is proposed the children should be at school. Still, so essential is primary knowledge, that we may with certainty assume that this objection, weighty though it be, will give way to general opinion; and what I would suggest would be, that those children who attend school for the limited time determined upon, should, when earning their food and clothes by labour, be placed in a situation to obtain fundamental technical—or, if it be better, to call it practical—knowledge on the farm; not by placing them indiscriminately one day to do one thing and the next another, merely to meet the convenience of the moment, but by putting them for a sufficient time under the shepherd, or the horse-keeper, or the stock-keeper, or the dairyman, or the engineer, or the hedger and ditcher, or the thatcher, that they may learn, as far as such labourers can teach them, the duties of their future calling. The only difference between the present system and that which I would suggest would be, that a youth employed on a farm should be so systematically engaged that he should early learn, by a species of apprenticeship, all that can be practically taught upon it, and that the shepherd, the dairyman, or the engine-man, as the case may be, with whom he should be placed, should receive a bonus for teaching him all he knows. In order to be assured that these teachers deserve their bonus, the youths should, at certain periods, undergo examination, and, where it be practicable, be made to compete with other youths for prizes. All that would be required in the way of national, district, or outside aid, would be the provision of qualified examiners, and the means of paying the teachers their fees and the youths their prizes. Already we have throughout the country, in the autumn, matches in ploughing, ditching, and draining, and the interest that the labouring men take in the competitions may be taken as some proof that, under proper control, competitive trials may be extended to farming youths engaged in various agri-

cultural duties. The payments to the labourers for teaching, and the youths for learning, would each act favourably in maintaining superior services on the farm, and thus the farmer himself would naturally become interested, and would give his support to the system. Youths would gain at one and the same time primary education at school and practical information on the farm, and the two descriptions of knowledge would tell with increasing advantage upon each other, and would finally effect what is really wanted—an improvement in the quality of the labourer's work, so that he may command increased wages for that work from his employer. At present the beer-shop is a great bar to the improved condition of the agricultural labourer. The influence of drink on an uneducated mind cannot be better shown than by the fact that beer or cider will go much farther than its equivalent in money in inducing men to exert themselves, although the money could be taken home by the labourer for the benefit of the wife and children as well as himself, while the beer or cider, if drunk, is dissipated in selfish indulgence. The quality of the beer and cider sold in the lowest-waged districts is the worst. The beer is seldom if ever genuine, and its effects are not to be measured by its immediate action on the system. It tells equally upon the physical energies of the man as upon the moral powers of his mind. The quantity of beer drunk in the hay and harvest time would surprise many of my hearers, though in the ordinary disbursements of a labourer—as ascertained by Mr. Purdy, of the Poor Law Commission—only one instance appears on record in which an expenditure in beer has been entered. I presume that case was the only one in which the wife had partaken of it as a necessary item of food. It is nevertheless true, that during harvest every able-bodied male labourer drinks beer which costs from 8d. to 1s. a-day, taking the average of harvests in the eastern corn-growing counties. I should be sorry to condemn beer as an article of food when properly made with good malt and hops, but that article is seldom to be met with. The liquid sold as beer in rural districts satisfies thirst at the time, and provokes it as soon as drunk, and it takes more vital strength out of the man than it ever supplies. I cannot speak too strongly against the prevailing excessive use of bad beer and cider. It is the bane of the farm labourer. In those counties in the West of England where cider is used instead of beer, the impoverished condition of the agricultural labourer is even worse than where beer prevails. His inferiority in work is mainly to be attributed to the bad character of the cider, and the excessive use made of it. There is some proof of the injurious influence of excessive drinking, in the fact that in all the worst-paid districts—where labour commands the lowest wages, and where those wages are all that the labour is worth—the publican and beer-seller bear a far larger proportion to the number of agricultural labourers than is the case in those districts where the wages are higher and where the labour is more valuable. We often hear mentioned the low rate of wages in the county of Dorset, and comparisons are made with the wages ruling in other counties. When we turn to the statistics giving the occupation of the people in the population returns of the last census, we find that whereas in Lincolnshire, which I select as the best cultivated county in England, the number of agricultural labourers is 52,871, and the number of people living by the sale of beer is 1,317; in Dorsetshire the number of agricultural labourers is 19,434, and the number of persons selling beer and cider is 582, showing a proportion in the former case of one beer-seller to 40 agricultural labourers, and in the latter one beer-seller to 33 labourers. The proportion in Lincolnshire is much too high; but what is to be said of Dorsetshire, where the labourers earning only two-thirds of the wages of Lincolnshire, support a larger proportion of beer and cider sellers? The figures given, moreover, do not fully represent the real state of things as regards the extent to which the beer and cider is drunk in Dorsetshire, as in that county a great deal of cider is given in lieu of money wages, whereas in Lincolnshire no such regular practice prevails either with respect to beer or cider. But I can illustrate this important part of the question by stating a case, within my experience, which can hardly fail to exhibit the fact that low wages and inferior work are associated with a preponderating use of beer or cider. In the year 1862 I had the control of some extensive drainage works in Dorsetshire, and at that time the agricultural money-wages of the district ranged from 7s. to 9s. a-week. Impressed that such pay was

inconsistent with suitable labour, I imported into the work some north-country labourers from Northumberland, practised in draining, to afford an example for such local men as chose to enter the trenches and dig by the piece. I guaranteed to the northern men a minimum of 18s. a-week, although I could command the services of as many Dorsetshire labourers as I desired to employ at half that price. The result showed that I was right in bringing high-priced competent men amongst low-priced inferior ones, for as soon as the Dorsetshire men knew what the north-country men were getting, and saw the character of the work executed by them, they applied all their energies in imitation. At first they drank more beer, thinking that by such means they could do more work. They soon saw their error, and it was both amusing and instructive at the same time to see how struck they were when they found that the northern men had for their dinners, good meat and bread, while they were living on bread, tobacco and miserable beer or cider. It was by very slow degrees that the Dorsetshire men realized the truth that butchers' meat was more strengthening than bad beer. Eventually, by the example afforded them, the "technical education" given them by the Northumberland men, and by the effect of improved food, the despised Dorsetshire men were enabled to earn as much as their teachers, and it was not long before I actually removed them into the north of England, to compete with Yorkshiremen in the work they had learned; and the first place at which they were engaged was Swine, in Holderness, where there did not exist a publichouse or a beershop in the village! If this experience of mine fails to convey what I mean, I can perhaps show that inferior work, low wages, and excess of drink, are attended by a greater amount of pauperism than belongs to districts where better labour, higher wages, and less beer prevail, by quoting from Mr. Purdy the result of figures he has given in his paper published in the *Journal of the Statistical Society*, which shows that whereas, in an example district in Dorset and Wilts, where the weekly wages were 9s. 6d., the rate of relief to the poor was 8s. 2d. per head on the population, in a similar district in Cumberland and Northumberland, where the weekly wages were 14s. 6d., the rate of relief was only 6s. 5d. Thus far I have spoken of those means of improving the condition of the agricultural labourer which will depend on himself and the force of education gained at school and on the farm. There are other means, however, by which the higher and middle classes in rural parishes may render material aid while the seeds of education are taking effect. I have said may render aid, because all Englishmen resist compulsion; but I feel those words are hardly strong enough when applied to some objects. I would rather say, will be induced to render aid by the influence of public opinion. I refer to four principal objects; first, to a more general substitution of good cottages for bad ones—cottages which will secure health and comfort in the ordinary living department, and provide separate bedrooms for the parents and children of different sexes, so as to secure comfort and decency, which have hitherto been incompatible with the dwelling of the farm labourer; second, the provision of a proper means for the drainage of villages and cottages, and the utilisation of the refuse which may be discharged from them. This is a matter upon which little has yet been done. We have drained large towns, and discharged their sewage into the rivers, a practice which the country has determined shall not be continued. At present we have not entered upon a mode of dealing with the sewage of villages and small communities; and whether it will be by the introduction of the dry-earth system (Mr. Moule's), or by any other process of utilisation, yet remains to be determined. The dry-earth system commends itself to the minds of many as the most suitable for villages, because each resident may preserve the refuse of his own cottage for the benefit of his garden without injuriously affecting his neighbour; and this being a very desirable object, the problem has to be solved how, by combined action, all the residents of a village may be brought into one common system of proceeding. As the wage-paid labourer cannot of himself do this, it would appear positively necessary that the owners of village property should take the initiative. Third, the supply of pure wholesome water in quantity sufficient to secure cleanliness and comfort to villages and cottages. I have already addressed the Society upon this important object, and will abstain from repetition. The supply to large towns is an easy matter, compared to the provision

of villages and small communities. But with our whole water supply undergoing change from causes we cannot control, and our village cottagers called upon to pay as much as a penny per pail for water, the subject must soon receive attention. And, fourth, the provision of ground for the recreation of those children which it is by common consent determined should be educated. I will now address myself to those objects in which the upper and middle classes of our rural parishes may voluntarily assist the lower class. Foremost amongst them are benefit societies. Of all things which the labouring man most dreads is his condition in his last days. By subscription to local societies (if well managed) a labourer may, under the present state of things, contrive to obtain the means of support if sickness overtakes him, but a provision for old age is an object which very few agricultural labourers secure. If the earnest interest of the upper classes in a parish could be manifested by taking a part in the management of benefit societies, very great good would attend them, and it would no longer be said that out of the 23,000 friendly societies which exist in England and Wales there are not 20 solvent. By importing into the mode of management the agency of the post-office as a means of securing safety of deposit and of insuring allowances in sickness and old age, as has been proposed by the Rev. J. Y. Stratton, in some interesting articles written by him in *All the Year Round* and in *The Cornhill Magazine*, the extension of such societies would follow. It was with a view to gain this advantage that the Kent Friendly Society memorialized the Postmaster-general last year, and I believe with good effect. All persons who have given their attention to the matter concur in objecting to the meetings of friendly societies at public-houses; and if the higher classes would really take an interest in them, the practice would be discontinued. "Sometimes," says Mr. Tidd Pratt, "the club is sold with the good-will of the house." Beer-house clubs are indeed a great abomination. Some few existing societies are excellent precedents for the establishment of others. The Essex Provident Society has enrolled between nine and ten thousand members, and has a capital of between £70,000 and £80,000; and the Hampshire Friendly Society has upwards of 3,000 members and a capital of £35,000. The Hitchin Friendly Institution, established in 1828, is, perhaps, based on as good a foundation as any in the country, as every member who insures against sickness is also compelled to insure for a pension in old age, an object declared by Mr. Hawkins, its founder and great supporter, to be of "vital importance if the wage-paid classes are to be taught the advantage of respectability in providing for themselves when past work without application to the parish." The next object which the higher classes can help the lower is in establishing and maintaining garden allotments under a provident system of management, by which a labourer, having allotted to him a rod of land, may pay, during his active life, a rent more than sufficient to satisfy the landowner, but which it is quite worth his while to pay, to secure the profit which the gardening of a rod of land will give. In the majority of cases a landowner who would not let a single rod of land to the labourer would let a plot of many acres to the parish authorities, and would be quite satisfied in receiving say £2 an acre, tithe free, which is equal to 3d. a pole or 10s. a rod. If the labourer paid 6d. a pole, or £1 a rod, tithe and rate free, he would be paying double the acreage rent that would satisfy the landowner, and if the surplus was invested through the same agency as that of the "Post-office Benefit Societies," it would accumulate so as to provide the rent of the land after a certain number of years, whereby the labourer in his latter days would hold the land rent free. Thus he would insure one means of support. But such an advantage can only be gained by the combination of the more wealthy parishioners, who together might become security to the landowner for the principal rent. Again, village hospitals and infirmaries, enabling the labouring class who have lived a worthy life to gain proper medical advice and nursing at home, are working well where properly managed, and are fit objects for benevolent co-operation. But besides these, there is still another, in which the upper classes may do much good. We have recently heard much of co-operative societies for reducing the cost of provisions, and preventing extortion on the part of London tradesmen. Without entering upon the question of whether such societies are desirable or beneficial for those they were originally intended to assist, it is quite certain that a modification of them may, with

great advantage, be carried out in villages for the supply of food and clothing to the labouring population in rural districts. At present there has been very little experience in co-operative stores in villages. There is no doubt, however, that the small wages of the agricultural labourer are much reduced by tribute to the local tradesmen; and with so little to spend as the labourer has, it is indeed desirable that that little should purchase as much as it can be made to do. One condition would be paramount, and that would be, that ready money should be the only means of purchase; but as this requirement would produce provident and careful habits it could not eventually militate against success. Associated with co-operative stores there might be established a common kitchen and bakery, at which food might be cooked with economy, and a better knowledge of cooking among labourers' wives acquired. Several efforts of this character are now being made in various parts of the country, but I am not in possession of sufficient information to speak of the results. I trust I may be allowed to close my remarks with an acknowledgment of the assistance I have received from numerous correspondents; among them I may mention Mr. Lawson, of Northumberland; Mr. Briggs, of Yorkshire; Mr. Skelton, of Lincolnshire; Mr. George Jackson, of Cheshire; Mr. Charles Howard, of Beds; Mr. Squarey, of Wilts; Mr. Morris and Mr. Castree, of Gloucestershire; the Rev. Prebendary Breton; Mr. Starge, of Bristol; Mr. Fowler, of Bucks; Mr. Mechi; the Rev. J. Y. Stratton; Mr. Charles Whitehead, of Kent; Mr. Whitting, of Cambridgeshire; Mr. Hagger, of Liverpool; and Mr. James Webb, of Worcestershire.

Mr. FREDERICK WOOD must say, at the risk of being considered a Malthusian, that one of the greatest causes of the miserable condition of the agricultural labourers had not been noticed, viz., their early marriages. It was generally the practice of farmers, if they had occasion to dismiss any hands, to select those for dismissal who were unmarried; and this, and the miserable condition of bachelor farm labourers, drove them to marry much earlier than they otherwise would. He was afraid there would be no real improvement in the condition of agricultural labourers until they were taught to look with more forethought upon so important a step as that of marriage.

The Rev. J. Y. STRATTON could say that beer-house-clubs were a great abomination. He had also stated that while the manufacturing operative had the hope of bettering his condition, and even of becoming, in course of time, an employer, the agricultural labourer had no such hope or object; and if he joined a benefit society, it was not one which would render him assistance in old age. The agricultural labourers of England looked upon the poor-rate as a kind of rent-charge, in lieu of that rod of land which Mr. Denton very properly wished to see them employed upon; and this was, no doubt, one reason for the early and imprudent marriages which had just been alluded to. He believed that, on the average, farm labourers married at the same age as members of the peerage; whereas it would be found that, as a rule, professional men found they must wait ten years longer before they could establish themselves. He did not wish to find fault with the poor-law, but he believed that in the next session of Parliament a commission would be appointed to inquire into the whole subject. The usual form of benefit societies in rural districts was what was termed a sharing-out club, which came to an end and was re-constituted every year, a contrivance by which the burdensome and aged members were got rid of and became ultimately dependent on the poor-rate. It was easily capable of proof that, on many of these sharing-out clubs, men spent more money than would support them in old age, and in greater comfort than was afforded them under the poor-law. It was estimated that, even in the present unsatisfactory condition of the vast majority of friendly societies, two millions a year were saved to the poor-rates by their agency; and this was enough to show what might be expected if an improved system could be introduced. Knowing pretty well the difficulties in the way, a farm labourers' society, in which he held office, one of the oldest and best friendly societies in England, some time ago memorialised the President of the Poor Law Board, pointing out the difficulties which were experienced in carrying out that law, and a memorial was also sent to the Postmaster-general, asking for some system of Post-office friendly societies. This proposal was worthy the attention of all those who were endeavouring to ameliorate the condition of the working classes. In conclusion, he would refer those interested in the

matter to a pamphlet which he had published,\* entitled "Friendly Societies & Beerhouse Clubs," which contained many important facts.

Mr. C. S. READ, M.P., wished Mr. Denton's paper had been read at the meeting recently held at Willis' rooms. He attended that meeting, and from statements made there it might almost be inferred that the English farm labourer was the most down-trodden being under the sun. One of the principal things there advocated was the establishment of trades' unions, which had been so thoroughly denounced in the paper that he need not trouble the meeting further about that question, except to say that, in his opinion, much of the effect of unions was already attained by the general employment of agricultural labourers by the day; the main object of unions was to do the least amount of work and receive the largest amount of pay, and that was really the effect of employing labourers, as was almost exclusively the case, by the day. Another scheme put forward was that of co-operation. Now co-operation between the employer of labour upon a farm and the employed, was visionary and impracticable; but there was one species of co-operation which would no doubt be successful, and that was the introduction of piece work, by which the greatest amount of work was done in the shortest time, and in the best manner. By this system a farm labourer could easily earn 25 per cent. more than on day work; it was usual in Norfolk to pay £6 a month in harvest time, but in putting out his harvest work by the acre, he (Mr. Read) found that his men could earn £7 or £8 a month. There was another matter which deserved special remark, viz., that although labourers in some districts only got nine shillings a week, and in others eighteen shillings, it was quite possible that the last-mentioned earned his money, and that the former was over-paid for the work he did. It should also be remembered that when men were spoken of as receiving 8s. or 9s. a week in the west of England, they often had perquisites which were worth 5s. a week more. There was no doubt that the old poor laws engendered and encouraged pauperism; and he feared that the present law, as it was too frequently administered, would have the same effect, though in a more limited degree. He believed that since the passing of the Union Chargeability Bill, granting of out-door relief had not been watched with the same careful scrutiny as heretofore, individual ratepayers not having the same interest to look sharply after it; he thought the practice of giving out-door relief was increasing, and ought to be most jealously watched. The people of this country ought to be taught not to look to the operation of the poor law for their support in old age; and to this end the upper and middle classes ought to do all in their power to encourage good sound friendly societies. Beerhouse clubs were really a curse to the labouring man, instead of a benefit, and generally failed just at the moment when they were most required. On the other hand, they must not go to such a rigid extreme as to disgust the labourers; for to men who had but few holidays, a harmless frolic once a year, on club day, was very wholesome, and tended much to increase the popularity of the club. There was another fact mentioned in the paper which he considered of some importance, that twenty-five years ago meat was 40 per cent. cheaper than at present; it was just about that time when they began to import foreign cattle, and the result, therefore, appeared to be that they had introduced foreign diseases, that farmers had lost a vast amount of cattle, and that the public had to pay much more for their meat. Mr. Denton seemed to think it rather strange that agricultural labourers were not admitted to the franchise; but they must remember that while the borough qualification had been reduced only from £10 to about £4, that for counties had been reduced from £50 to £12; and if the present bill was spoken of as a leap in the dark, he considered that one which would give the franchise to the agricultural labourer would be taking a jump into the bottomless pit.

Mr. JAMES HOWARD said the gentleman who had spoken of the evils of over-population could hardly have had much experience in rural districts, or, at any rate, he could not have had to harvest some 500 acres of corn. The truth was, that we were beginning to feel the evils of under-population. There were so many excellent points in the paper that he was very reluctant to take exception to anything, but he certainly

thought that rather too bright a picture of the condition of the rural population had been painted. There were yet sadly too many villages and districts neglected by those whose duty it was to care for them; and the noble example set by the Duke of Bedford and others in covering their estates with excellent cottages and schools had not been followed to anything like the extent it ought to have been. There was no doubt that the condition of the agricultural labourer had much improved during the last twenty-five years, and this he attributed, in a great measure, to the improved system of agriculture, under which there was much more demand for manual labour than in the primitive system which it had superseded. The introduction of Swede turnips, and a regular system of root culture, had added millions to the national wealth, by enabling the farmer both to grow more corn and also to feed more stock; and this had improved the condition of the labourer, not only by finding employment for a large number during the summer, but also by providing them with something to do in the winter, when otherwise they would have been idle. The greater facilities for travelling, our large public works, railways, and land drainage had also had something to do with this state of things, and the introduction of machinery upon farms had had a great influence—having broken down that dead level which so long existed in the rate of agricultural wages. When a man was employed to swing a flail which only cost a shilling, 2s. or 3s. a-week difference in wages was a great consideration; but when the same man had to attend to a thrashing machine which cost £400, a difference of a few shillings to a steady, skilful, and trustworthy man was a mere bagatelle. So with the steam-plough. Men were now paid more for sitting on a steam-plough and directing its movements than they formerly were for breaking up the stubborn soil with great labour. The condition of the English labourer contrasted very favourably with that of the French peasant, who, as he had found from frequent observations last year, was generally, on large farms, in the receipt of about 1s. 7d. a day, for which he had to work from four o'clock in the morning until eight o'clock at night, and until noon on the Sunday, whilst he slept in the same hovel with the bullocks. Under such circumstances it was not very surprising to find that most of the men were unmarried, and their whole condition was about as comfortless as could be well conceived. Notwithstanding what had been said by the hon. member for East Norfolk on the effect of the Union Chargeability Bill, he believed it would have a material influence for good on the future of the labouring population. Under the former state of things, landlords had a direct inducement to pull down cottages instead of building them; but under the present system all that was changed; and this was very important, for one of the main things which ought to attract the attention of the landed interest was how to increase not only the number but the quality of the habitations of the poor. Under the present Act the labourer was freed from the serf-like necessity which bound him to his own parish, and he was able to travel over the union in search of employment; and he (Mr. Howard) hoped the day would soon come when this limit would be yet further extended.

Mr. C. S. READ asked leave to explain that he did not object to the principle of the Union Chargeability Bill, but only to the mode in which relief was too often administered under it.

Mr. J. K. FOWLER (Aylesbury) said, beginning with the question of labourers' dwellings, he believed that was one of the most difficult things that had to be considered. They had heard what was the cost of a decent house; and he need hardly say that it was impossible for an agricultural labourer to pay, as rent, interest even on £140. He had had, through his landlord, to build one or two cottages, and he found they cost from £130 to £140 each—for they ought all to have three bedrooms—and this represented a greater rent than the men could pay; but he believed the tenant-farmers would willingly co-operate with the landlords in this matter, and take upon themselves the rental of any reasonable number of cottages, to be included in the rent of the farm and buildings, which they would let to their men at a moderate rent, and also give them garden-ground to cultivate. He gave each of his labourers half-a-rood of the best land on the farm, as near as possible to the farmyard, and told them to take whatever manure they wanted; and once a year, when "harvest-home" came round, they had a little exhibition of the garden produce. All this had a most excellent effect in keeping them from

\* Ridgway, Piccadilly.

the beerhouse, and in encouraging habits of independence and industry amongst them. The question of wages was one that would settle itself, especially where a man was no longer tied to his own particular parish, but allowed to go to an adjoining one, where he thought he could find a better master or higher wages. With regard to what Mr. Denton very appropriately named "practical education," that was a point which could not be too much insisted on. Being very anxious that a good ploughman in his employ should be taught even further excellence, he got his friend Mr. James Howard to have him taught; and the result was that at the next county ploughing match he won the first prize, and a great deal of attention was excited amongst the other men to see how he set his plough and went to work. He believed that the agricultural labourer, if properly educated, might be made as good a skilled labourer as any man in the manufacturing districts. He (Mr. Fowler) was now using the steam plough, and every man engaged in attending to the machinery, including the one who drove the engine, was, a few years ago, an ordinary agricultural labourer. Mr. Denton had spoken of bakeries for the benefit of the men, but he did not well see why they should not have public breweries as well, so as to avoid the bad beer so much complained of, only it would be quite necessary that the present oppressive malt-tax should be removed. The supply of water to the dwellings of the poor was of even greater consequence than that of beer, and should never be overlooked in the erection of cottages.

Mr. C. WREN HOSKYNs regarded the whole question very much from a point of view which had not been touched upon, and which he could not pass by in absolute silence, namely—the position which, in regard to the constitution of the whole order of English society, the agricultural labourer held in the body corporate. They had a body of laws relating to landed property, which were peculiar to England, which they had attempted to enforce upon the colonies and to establish in India and America, but which had broken down in each of these instances, and which existed in no other country in the world with the exception of portions of Austria and Russia; he referred to the laws which tended to the aggregation of land into large and still larger territories—he could not call them estates—of from 5,000 to 10,000 acres, and which it was morally impossible could be farmed by the proprietor. It had, therefore, to be let out in portions to tenant farmers. If these tenancies existed for the term of human life, or even for twenty-one years, or any such term as would give something like a feeling of proprietorship, it would matter little who the owner of the soil might be in reality; but at present the effect was to make all the efforts of the farmer point to those discoveries which suited his circumstances, and would enable him to make the most out of the land in the shortest time. He admitted that this system was very satisfactory to farmers and proprietors; but there was one individual who would raise his voice against it if he had the power, and that was the one whose condition they were discussing—the agricultural labourer, whose position was such that he did not come in contact with the owner of the cottage which he inhabited, or of the land which he tilled. The tenant who employed him held his lands under such conditions as compelled him to make the most out of it in a short time, and with the least expenditure of labour; and, under these circumstances, he did not stand on equal footing with the man who came in contact with the actual owner of the soil; and, in fact, those men who were employed about the gardens of the proprietor, were always in a better position, had better wages and dwellings than those who worked for the tenant farmer. The latter was not able really to influence the condition of the labourer; the cottage in which he lived did not belong to him; the farmer might leave the farm and the labourer stay, or the labourer might leave while the farmer stayed; there was no life-long relation between them of that kind which rendered the man's condition an improving one, because of his labour becoming more appreciated. He thought, however, their condition was capable of great amelioration, and no doubt machinery operated in agriculture the same as in trade, though the conditions were not exactly alike, because in the one case there was the power of almost unlimited production, while in agriculture the production though not so limited as some might suppose had a definite limit. He should most gladly see any system established which would improve the condition of the

agricultural labourer, but he thought more good would be done by commencing at the other end of the chain of causes, and endeavour to obtain some alteration of that system which was tending to larger and larger aggregation of estates. One point in the paper and discussion he had noticed with much pleasure, the importance of technical or practical education. He had himself seen the work of a farm done altogether inefficiently, simply because every one was trying to do everything, and because the system seemed to be a miscellaneous one by putting any man to any employment. If there were more subdivision of labour on farms he was certain good results would follow, and one of the main advantages of technical education would be that each man would be able to do at least one thing well, instead of a great many things indifferently.

Mr. S. SIDNEY said Canon Girdlestone had proposed one of the few things which would really do the labourer good; when he found that in one parish or district the wages were very low indeed, he recommended the men to go elsewhere, and that was just what caused the great superiority of mechanics to farm-labourers; they were much better educated, not so much in the way of reading and writing, but in knowledge of the world, and how best to provide for themselves, and improve their condition. The agricultural labourer must not be limited to the mere bounds of his parish, as was now too often the case. The fathers of his (Mr. Sidney's) friends the farmers were anything but alive to the advantages of education; they did not like a labourer who had an idea beyond his own parish.

Sir GEO. JENKINSON had not heard the paper, but Mr. Hoskyns had admitted that large owners were the best employers of labour. He understood him to say that in the neighbourhood of large owners the labourers were well paid and cared for, and lived in good cottages, but that the reverse was the case where tenant-farmers were occupiers; and what was the inference, but that where there was most capital there would be the best remuneration for labour? He did not believe education would enable a man to till the ground better than his fellow who had had no education. An exemplification of this was to be found in the case of railway navvies. There were no men in the world who had so much physical ability to do an enormous amount of work; they laboured from Monday morning until Saturday afternoon, and, as a general rule, were drunk from Saturday afternoon to Monday morning. They received enormous wages, and consumed an enormous amount of beef and beer, and did far more work than any agricultural labourer; but what enabled them to do so was not education, but the amount of food which they consumed. In the same way, education would not enable the agricultural labourer to do more work. He was, however, not the less an advocate for education, which it was the duty of the upper classes to give to those below them, but he did not like the question put upon a false issue. He had lately seen in the papers the detailed case of a man with a large family of ten children, the eldest of whom earned 3s. 6d. a-week; and when the man was asked about sending the lad to school, he replied that it was not the question of the penny for the schooling, but of the 3s. 6d. which he earned, and which made just the difference between living and starving. That was the great difficulty which had to be met with in reference to education, and which, he thought, it was impossible to get over.

Mr. J. BENNETT had a farm in Sussex, on which he employed some seventy men, but he found it a growing difficulty to provide habitations for them, and some had to walk four miles to their work. He could not get a bit of land on the roadside on which to put up any cottages, and he did not know how to remedy the evil, which was a very grave one. Mr. Hoskyns had alluded to the land laws, but he thought the game laws had also something to do with the question. The great landowner attached much more importance to the game than to the condition of the labourer, and would not have a cottage in this place or that, lest the game should be interfered with. As to the state of education, he (Mr. Bennett) had offered a shilling to each of his men who could write their names, but not ten of the seventy could do so, and the question was, how this ignorance was to be overcome. In some places the parson would assist them, and in others he would not, or could not, and then the case was hopeless. Some of the clergy were afraid of the men becoming too independent, and thinking for themselves; and the squire thought education would make them saucy, and that if they learned anything beyond the

limits of their own parish they would draw comparisons, and that when improvement once began they would improve themselves off the land altogether, and go where they believed they would be better off.

Mr. W. HAWES (the chairman) said it appeared to him that Mr. Read was not sufficiently informed about trades' unions when he spoke of the system of day work having the same effect, which was enabling the men to do the least work and have the highest pay. The object of trades' unions was to bring men together to agree to a uniform rate of pay, which they thought most conducive to the welfare of all; and he could not agree that the effect of trades' unions was such as Mr. Read had stated it to be. Then the same gentleman went on to trace the effect of legislation in introducing foreign cattle, and drew the inference that that had been the cause of the increase in the price of meat, stating the price of meat so many years back; but he forgot that there was an intervening period when meat was quite as high as at present, long before the operation of Sir Robert Peel's Act—certainly long before the introduction of contagious diseases by foreign cattle. The fact was, that if the importation of foreign cattle had been injurious, they must not forget that long before the disease was introduced hundreds of thousands of foreign cattle had been imported, of which the country had had the benefit.

Mr. C. J. READ said he had not alluded to the cattle-plague but to pleuro-pneumonia and other diseases of a similar character. The CHAIRMAN said that if the state of the case was as bad as Mr. Bennett seemed to think, it appeared almost hopeless; but if the labouring classes did, as he believed they would, gradually improve, there would be an increase of produce from the land, and the whole class would rise considerably in the social scale. No one seemed to have noticed that which he (the Chairman) principally relied on—the appropriation of a certain number of hours to

general education, and a certain number to practical instruction in farming pursuits, so that in a few years they would be in a position to earn the highest rate of wages in their calling. Then there was the question of the improvement of their dwellings, which had been taken up by this society again and again, plans having been prepared, and every possible scheme suggested for reducing the cost, but they could not bring it within £130: they could build a hovel for a great deal less, but not a cottage fit for a labouring man to live in. If they had improved dwellings, and the other things which had been mentioned, gardens and friendly societies, and co-operative stores which might do a great deal in enabling them to supply themselves on the lowest terms, they would soon be in a much better position; and above all, if they could induce these men, not by legislation, but by showing them the benefit of it, to abstain from the beershop, their greatest enemy would be conquered. They must not go away with the idea that the navy was such a deplorable creature as the hon. baronet had painted him: they were not, as a rule (and he knew a great deal more of them than of agricultural labourers), drunken or unintelligent men—they were one of the most intelligent class of workmen in the country. Take a navy abroad, and he was the most valuable man you could get. Place him in circumstances of great difficulty, requiring coolness, intrepidity, and perseverance, and the behaviour of these men was most remarkable. The great works of the country could not have been accomplished but for the energy and discipline which existed amongst them. Most of them had attended national schools, and had a certain amount of real education; and it was this combined with their practical knowledge, which made them such valuable workmen. There were drunken navvies, no doubt; and in this, as in other cases, people were apt to judge a class by a few.

A vote of thanks was passed to Mr. Denton.

## THE MANAGEMENT OF CATTLE.

On every farm on which a profitable course of alternate husbandry is being successfully carried out, the connection between corn and cattle is inseparable. Corn may for a succession of years be low in value, yet it must be grown to provide food and litter for the animals of the farm, so that there may be no break or interruption in the supply of manure. The foundation of modern farming where success is aimed at is manure, unsparingly and ungrudgingly applied; but little can be accomplished without it, and no process or system of cultivation, however elaborate, has been discovered, or is likely ever to be, which would do away with the necessity for its use. The most fruitful source of manure within reach of the farmer is the stock of cattle kept on the farm, the quantity made during the season being more or less, according to the number of animals kept, and both quantity and quality varying to a much greater extent than is generally supposed, according as the food supplied to the stock is nutritious or otherwise. The dung of poorly-fed animals is hardly worth the trouble of carting out, being but of little other use than serving to keep certain soils open, enabling the air to circulate, and so act beneficially by its ameliorating and disintegrating influence. The dung of well-fed animals, containing as it does all the elements of nutrition, not only alters the texture of the soil, but enriches it, the effects of a dressing of pure dung from highly-fed animals being immediate, and also to some extent permanent. Taking advantage of this principle in the character of farmyard manure, we find that the leading agriculturists of the present day base their success on liberal feeding, expending large amounts on the purchase of concentrated food, besides supplying abundance of that which is home-grown. The extra profit obtained on the stock fed with these substances would scarcely ever repay the feeder, did he trust to that alone; and he therefore looks to the extra value of the manure to recoup him for his outlay. A farmer without having the slightest knowledge of chemical analysis can, in the laboratory which nature has provided, easily experiment for himself, and ascertain without the slightest risk of failure the exact difference of value between a load of manure made by animals in good

condition and liberally fed, and the same quantity from animals in poor condition and living on food of poor quality, even although they may be getting as much of it as they will consume. In this instance one trial is sufficient, as it will be speedily proved that a single load of well-rotted pure *manure*, such as we have described, will give better results in the field than three when the beasts have been poorly fed. The difference is especially noticeable with crops of quick growth, such as Italian ryegrass, tares, &c.: the crop is heavier far; and, again, what is of almost equal importance, the crop is forced forward with such rapidity by the superior excellence of the manure, that a fortnight at least is gained at a period of the year when a supply of succulent fodder is oftentimes urgently wanted. Manure, therefore, being constantly in demand for the purpose of keeping up the fertility of the soil, and cattle being the principal source of production for this valuable and indispensable constituent in agricultural economy, there ensues that connection between corn and cattle husbandry, which, under ordinary circumstances, renders them inseparable. We thus find that cattle, whether they pay or not, must be kept by the arable farmer who desires to be successful in his business; and he is the most prosperous who, keeping a stock of cattle, makes that stock profitable—not only in a secondary or subsidiary sense by the assistance they render him in raising paying corn crops, but also makes a separate, independent, and clearly-ascertained profit on every animal of which that stock is composed. We have at least one very high agricultural authority holding the opinion that this cannot be done, and that the farmer must look to his corn alone for all the profit he may legitimately expect from his live stock; we have, however, an equally high authority holding quite the contrary opinion, and we ourselves, judging from our own experience, look upon all farming as a very miserable affair, where no profit is derived from the cattle kept except that obtained through the manure which they supply and the increased quantity of corn the farmer can by its assistance be enabled to grow. It is our opinion (and one which we feel assured is shared by most practical men) that

the British farmer has not the slightest reason to dread that the home-production of meat will ever be over-done, or that it can ever exceed the demand except for exceedingly limited periods. Bad trade, for instance, by lessening the amount of money circulating in the country, has frequently the effect of reducing the price of meat by a decreased demand, and the value of live cattle is consequently somewhat affected thereby. Corn, keeping at high rates for a season, also to a perceptible extent limits the consumption of meat, and has while it lasts a correspondingly depreciating tendency. Either of these influences however are seldom so powerful or so long-sustained as to affect the average of a whole year to any appreciable extent, the intervals during which meat remains low being usually so short as to enable the stock-holder so to manage his home-arrangements as to secure at least a good average, if not the very highest quotations for the year. Judging from what has taken place during the past year with reference to the introduction of fresh meat from foreign countries, it is not improbable but that we may very shortly have considerable importations of that article in a condition that will enable it to enter pretty freely into consumption in Great Britain. The principal sources of supply—Australia and South America—are however so distant from this country as to almost preclude the possibility of its being sold at such a price and in such quantity as to effect in any very sensible degree the interests of the British agriculturist. However well the preserving process may be accomplished, it can scarcely be expected to be equal to meat that has been fed and slaughtered at home; and in all likelihood it will tend more to increase the consumption of meat amongst that portion of the population with whom it is at present but little used, rather than to displace it on the tables of those who at present are the largest consumers. It is a matter of extreme difficulty to obtain for imported meat a permanent position in the markets of this country; the slightest difference in colour, texture, taste, or (what is perhaps most important of all) *smell*, to the home-article which it represents, and which it is expected to some extent to supplant, forming an almost insuperable barrier to its successful reception by the British public. Tastes must be acquired and prejudice overcome before it will be generally accepted, and this too after scientific men have been engaged in laborious investigation, it may be as in the present instance for many years, in solving a mode by which the meat can be preserved and transmitted. Science, truly, can and has surmounted many difficulties and vexatious perplexities, but is comparatively powerless in creating new tastes or subduing prejudice, a notable example in proof of this being afforded by the recent attempt to introduce the use of horse-flesh into England as a means of increasing the meat supply, and thereby lowering the price of beef. The publication of Mr. Frank Buckland's letter has apparently given a complete quietus to the organization which had this for its object, no more having been seen or heard of it—at least in the columns of the public journals. Yet here science did its utmost, the most skillful men in their profession having been procured to prepare the banquet (so called); but all the modes of preparation with which these artists were acquainted, combined with the most piquant and appetizing seasonings, could not overcome the prejudices of the guests, or prevent their subjecting each delicate morsel to an olfactory test before submitting it to the scrutiny of the palate. When intelligent and cultivated men could make such a poor dinner on this meat, and it, too, so well disguised, it is hard to suppose that it would be accepted by the class its promoters expected it to benefit, who, as a class, are above all men notoriously difficult to please, and whose prejudices in regard to new or untried articles of food are much more deeply rooted, and probably more difficult to overcome than even the higher classes. One could easily imagine the howl of derision with which any gentleman would be met who proposed to his servants to dine off a roast loin of colt or filly which he had slaughtered for home-consumption, having for some reason or another found the animal unfit for any other useful purpose; or again, did he inform them that having fattened-up a superannuated carriage-horse, for the purpose of being utilized on the table of the servants' hall, it would require but little stretch of imagination to suppose that they one and all gave him warning on the spot, and that he was politely requested to provide himself with a full retinue of new servants on that day month. Anyone who knows anything of the difficulty experienced in getting servants to eat beef or

mutton which has been killed on account of injuries from kicks or other accident received in the field, and which they have in some way or other got an inkling of, can form a very fair conception of how any new and particularly economic article of food would be received, whether that was home-raised horseflesh, Australian mutton, or beef from the South American prairies. Well-paid tradesmen in towns and large cities, and well-to-do country people, are all equally particular about the quality of their meat, few being willing to take anything but prime joints, when the state of their eschequer permits of its being done, preferring rather to go without when they cannot do so. Taking everything connected with the habits of the people into account that bears upon the consumption of meat, and consequent demand for cattle, there appears to be but little danger for many years to come, if ever, of any farmer rearing cattle which will not reimburse him for the trouble and expense he has been at in bringing them to the selling point, both in the fertility imparted to his fields by the manure he has made by their means, and by a separate profit upon each animal, after charging it with the full value of the food consumed. To ensure success, it is essentially necessary that everything connected with the management of the stock should be done in the best possible manner, every minutiae being observed which has the slightest tendency to conduce to their welfare and progress, and so facilitate the end in view. The object of the present paper is to review a few of the leading points necessary to be attended to in the management of cattle on an arable farm, where the cultivation of corn and the breeding, rearing, and feeding of cattle are simultaneously carried out.

Spring is a period of the farmer's year, during which his attention must be devoted more particularly to the care of his live stock. At that time the bulk of his breeding animals are dropping their young. The comfort and health of the mothers and the welfare of the little creatures newly-ushered into the world must therefore be looked after with more than ordinary assiduity. When he has had the forethought to take the trouble, and go to the expense of procuring good sires, the extra labour involved, instead of being felt as a burden, becomes a source of real pleasure, the owner feeling satisfied that under ordinarily fortuitous circumstances his prospects of remuneration are all he could possibly wish for. In cattle breeding, the selection of the male should be gone about with no spirit of parsimony, but rather with an excess of generosity and thorough determination to secure a first-class animal whatever the cost. The influence of the male on the character and value of the future produce is now so well known and generally understood and acknowledged as to make it really surprising that a cross-bred brute should be used by any one at the present day who has such a number of animals in his herd as to warrant the keeping of a valuable bull. Whatever the breed, there is no better investment of capital by an agriculturist than that expended in the purchase of a sire of good descent, the profits being not only large, but continuous, the influence of one really good animal extending for years. Although it is desirable in a milking stock to have the bull descended from a line of cattle famed for their milk-producing properties, that feature in the character of a herd being also transmitted, it is not nearly so important as when the object of the breeder is purely the production of beef. That the produce of a cross-bred bull often turn-out excellent milkers, is a fact easily proved, as many owners of dairy-stock take very little trouble about the selection of a sire, paying but slight attention to his breeding, providing he is moderately straight and level along and over the back, of a good colour, healthy-looking, and cheap. On account of this indifference and seeming negligence on the part of stock-holders, the animals, in numerous cases, are so altered in form, colour, and general configuration, that it is impossible to recognise the breed from which they originally sprung. Notwithstanding this peculiarity, the milking property is seldom injured to a perceptible extent, many of the cows composing such a herd being extraordinary milkers. It is, however, very different when the herd is maintained for the purpose of raising stock to be fattened for the butcher, as the use of any other than a highly bred bull becomes then simply a picking of one's own pocket. It must be admitted that useful beasts for the stall are often to be met with, neither the sire nor dam of which was pure bred; but, all other things being equal, the superiority of those animals, the sire even of which has been pure bred, is so marked as scarcely to admit of

comparison. Without a particle of extra care, pure breeding conduces to economy of food, to laying on flesh quickly, and to early maturity. The advantages derived from these distinguishing characteristics are numerous and valuable, but all tending to one pleasing result, viz., the increase of the farmer's capital. A half-bred heifer, the sire of which was pure, can be easily finished for the butcher at the age of two years, bringing as much money then as one of three years, which had the disadvantage of being cross-bred by both sire and dam. Here there is all the expense attendant on the maintenance of a large animal for an entire year saved—in itself an immense thing, quite sufficient to enrich the farmer who takes advantage of it, and to impoverish him who neglects it, particularly now-a-days, when excessive competition for land, and dear labour cut down the farmer's profits to the lowest possible point.

Britain possesses several local breeds of cattle for meat-producing purposes, a few of the more noticeable being the Hereford, Devon, Polled Angus, and West Highland, all good, some of them indeed of rare merit, as the Hereford and Angus, but mostly confined to the districts from which they derive their name, and difficult to be got pure in any other part of the country, unless with a fancier of the breed. The Shorthorn, which would seem by general acceptance to have been received as the breed, of cattle most suitable for the improvement of existing breeds is now to be met with in great perfection in every part of the kingdom. By whatever name a cow may be designated—whether Ayrshire, Kerry, Highlander, or cross-bred—or however shabby and insignificant she may appear, if crossed by a pure-bred shorthorn her produce will partake so much of the character of the sire as to make it, with fair treatment, both useful and profitable. Even to the very fastnesses of the Highlander himself has the shorthorn penetrated; and excellent butchers' cattle, the produce of a Highland cow and shorthorn bull are yearly fed in the western islands of Scotland, and sent round by steamer to Glasgow. The distilleries on these islands afford a good supply of food in the shape of grains, these styled draft, on which the cattle thrive well, and require but little outlay for oil cake, turnips and grains being able to finish a heavy beast with but little assistance from the more expensive article. No particular difficulty need be experienced in getting a useful sire of shorthorn blood, pure stocks being now so equally distributed over the whole kingdom. The expense, also, is not by any means great, when the value of the breed is taken into consideration, the days of extravagant prices being numbered, unless for stocks of very high character. During the past few years many herds of shorthorns have been founded, and managed on more sensible principles than was originally the case. Formerly it seemed to be supposed by every possessor of a herd of shorthorns that as the breed was capable of carrying an almost unlimited amount of flesh, it therefore became absolutely necessary so to pamper each animal that it might become a specimen of what the breed would attain to, and the enormous load of meat it could be made to carry. This was frequently done to such an extent as to reach the stage of actual cruelty, the poor beast's very existence being a burden; and thus money was not only spent uselessly, but the animals, both male and female, were often so injured by excessive obesity as to be unfit for anything but slaughter. Now, however, the breed having got into the hands of men who cannot afford to measure the treatment they give their cattle by any other standard than that of pounds, shillings, and pence, pure-blooded specimens can be had, which have been rationally treated, thus combining two important advantages, their constitutions not having been impaired by over-feeding, they are eminently suitable for reproductive purposes; and the cost is greatly less. A young bull of either Booth or Bates blood, and a good one too, can now be got for thirty guineas, which, having been used to the ordinary food of the farm, is in no danger of falling away when removed to other quarters, but, on the contrary, having a tendency to improve, especially if his new owner is disposed to be kind to him, which is extremely likely to be the case. Thirty guineas is a large sum for a man of limited means to give for one animal, whatever its merits, or however much benefit he may look forward to by the use of that animal; yet for the small farmer, whose stock consists of but ten or fifteen cows, the possession of a pedigree bull is so essential to his interests, that the getting of one is worthy of a strong effort on his part. Two

neighbours who are on friendly terms can serve each other very materially, by joining in the purchase of a bull, thus dividing the risk, lessening the amount to be expended by each party to half, and thereby probably bringing it within reach of both, and doing the business required to as much purpose as if both had got a bull. In a partnership of this sort, an animal cast by a wealthier neighbour may often be procured, giving them the advantage of having one of whose merits they have had previous opportunity of forming an opinion—a point of no inconsiderable value. Such a bull, being come to his full growth, and consequently weighty, will in general bring his first cost when sold to the butcher; so that, by a little management, the services of a pure-blooded bull can be had at no further expense than that incurred by feeding him during the short period he is required on the farm. Surely the importance of this matter ought to be sufficient inducement for a farmer to take a little extra trouble in looking about for a really useful beast, instead of contenting himself with a mongrel, whose produce at twelve months old will be worth not more than two-thirds of what they would have been had a pedigree-bull been used, the treatment being in both cases exactly the same. One of the most useful bulls we have known was repurchased, when four years old, by his breeder for £25, from a party to whom he was sold when a calf for one hundred pounds. The breeder having seen his produce knew his value, and got him just at butchers' price, and the animal was subsequently so valuable that he would not part with him for three hundred. This was, of course, an exceptional case: the breeder being an excellent judge profited by his knowledge, and prized highly what another discarded. An ordinary farmer could not make such a lucky hit very easily, but following this example, and acting upon the same rule, would be largely benefited by introducing blood into his stock at comparatively little outlay, the high price of which under any other conditions would keep it beyond his reach. Having gone to considerable trouble and outlay in introducing good blood, it is highly necessary and well worth while for any one who has done so, to pay an increased amount of attention to his cows during the period of gestation, so that, apart from circumstances over which he has no control, they may get a fair chance of bringing into the world a fully matured and healthy calf.

It is intensely galling to lose the well-earned fruits of skill, capital, and labour through the carelessness or inconsideration of those in charge of the animals; but there are certain disturbing influences quite out of the province of the attendant, and which every owner of stock should do his utmost to guard against, or if they exist to remove them, as far as lies in his power. Uneven passages to and from the fields or to drinking-ponds are injurious to cows heavy in calf, and should be kept as even and smooth as the nature of the surface will permit. Narrow doors from the stalls are also highly prejudicial to the cow and her future offspring, as in spite of the utmost care cattle will crush each other when going out and in, so much so as in many instances to inflict extensive local injury by the excessive straining. Where a large or even moderately-sized stock is kept the utmost facility for entrance and egress ought to be allowed, the doors or rather gates being wide enough to admit an ordinary cart, and placed at convenient distances. Strict attention to ventilation and good drainage will also be given by the careful and considerate owner of a breeding stock, and if a constant circulation of pure air is kept up, one of the most fruitful causes of abortion is neutralised, viz., foul air. Some attention is required to be given to the feeding while turnips form a large portion of the diet, as a cow will readily slip her calf after feeding heartily on cold roots, if the stomach has been comparatively empty. Giving the hay or straw with which she is supplied in addition, the first thing in the morning, counteracts this tendency in a great measure. No trouble ought to be considered too great which has for its object the prevention of cows prematurely slipping their calves, as when it begins in a herd it seldom leaves it without inflicting extensive injury and consequent loss.

The cow having produced a full-timed, healthy calf, the leading idea of its owner in connection with the young animal should be to keep it so, and this is in general attained without much trouble, save by providing it with airy and comfortable quarters and a plentiful supply of nutritious food. To ensure from the very commencement of its existence a healthy organization, it is a good plan, when it can be managed, to permit

the calf to suck its mother for the first few days—that is, until the milk has assumed its natural colour and become fit for use. Although excellent in theory, this is especially difficult to carry out in practice; the instinctive feelings of both dam and offspring having been aroused, it is some time before they can be got to forget each other, and unpleasant consequences are apt to ensue when the separation has been effected. The calf having for these few days been accustomed to drink with its head elevated, it is hard to make it understand that the operation can be quite as comfortably performed with the head down, and it displays considerable obstinacy on this point. A little hunger soon brings it round, and leads to the required alteration in the habits and instincts of the little creature; and it is much better to give time, and leave it to the teachings of hunger, than compel it to keep its head down by main force. In the case of the cow more is to be apprehended than a little annoyance, there being positive danger of present loss and permanent injury when she has taken kindly to her calf, and resists the separation. In constant expectation that she will be permitted to rejoin it, she retains the milk, in spite of repeated and long-continued efforts to withdraw it by hand; and when thus retained severe inflammation is immediately set up, and the poor animal is in imminent danger of losing a quarter, or, in extreme cases, a half of the udder. The moment it is noticed that the cow is holding her milk, the calf should be allowed to suck, so as to relieve the pressure and prevent inflammation. The udder being thus softened, the milking may with great propriety be finished by the dairy-maid. This may be continued for a few days, until it is known, by the softness of the bag and the uninterrupted flow of the milk, that the danger is past. Should the calf not be re-admitted, or even delayed so long that the swelling has become intensely painful, the opportunity for relief in this manner is lost, and the udder must be softened by fomentation with hot water and the application of soothing and repellant ointments, involving a considerable sacrifice of both time and trouble. The probability of symptomatic fever of this kind occurring from partial or total suspension of the milky secretions renders a system excellent in theory, highly objectionable in practice, and in consequence the calf is, in most cases, removed to his own crib immediately after having been licked dry by the mother, the connection between them never again being renewed. This, of course, particularly refers to stocks where profit is looked to from the dairy, as well as from rearing, as in districts where the latter is the principal object the calf is left with its mother until reared. The calf now being dropped, it may reasonably be thought that it must be a very poor one indeed, if not worth rearing, providing the sire has been well selected and the dam ordinarily good. Yet even under the most favourable conditions with regard to the parents, there will now and again be calves dropped not worth the trouble and expense of rearing, particularly in the case of male calves, whether intended to be kept entire for breeding purposes or for feeding for the butchers as bullocks. It is well, therefore, that a little judgment should be exercised, and each calf subjected to a rigid scrutiny before any expense is incurred, as an ill-thriven animal is not only a loss, but a positive eyesore while it remains on any farm. It is much better to send an excessively narrow-backed, flat-ribbed, or drooping-rumped calf at once to the butcher, and get a few shillings for it, than keep it on and risk the loss of pounds by feeding it for several years, consuming food which might otherwise be profitably employed in feeding an animal which would by its superior conformation have a fair prospect of leaving something for its keep. A delicate-constitutioned cow may often be worth holding over for her superior milking qualities; but unless of a rare breed, when it may be worth while to run a little risk, her offspring are seldom worth the trouble of rearing. While milk is plentifully supplied to it, such a calf will often look as well as its comrades, and have all the appearance of thriftiness; but if it inherits its mother's delicacy, which it almost invariably does, it begins to fall away from the time that it is turned out to shift for itself. If it survives the winter it is mostly a gaunt-looking object, with not the slightest appearance of ultimately becoming either valuable or profitable. Well-bred cows and those which have been long milked, however bred, frequently drop their calves very small, in some cases remarkably so. When well-formed, healthy, and full-time this is not particularly objectionable, as liberal treatment soon pushes them on, a few weeks being sufficient to bring

them to the standard of those of the same age, which were an average size when dropped. It is very necessary when a considerable number of calves are being reared together to confine them in separate cribs so as to prevent their sucking each other, a habit as disgusting to the on-looker as injurious to the poor animals themselves. Where not convenient to have a crib for each calf, a little collar could be provided and slipped over the head of each one as soon as fed, the fastening being just as far distant as will prevent contact. The confinement when the warm weather has arrived, and their owner is desirous of putting them out during the day, need be only temporary, as the intense desire which they evince for sucking is shown most strongly for half-an-hour or so after being fed. When this habit is not prevented there is almost a certainty of a few deaths occurring each season from the hairs thus taken into the stomach collecting into an indigestible mass, the poor things dying in frightful agony. The indestructible nature of the materials forming this ball renders a cure next to impossible; prevention is therefore all the more necessary to be attended to, and there is no better preventive than the modes of temporary separation we have now described. Although nature indicates that milk warm and unmixt as it comes from the cow is the natural and proper food for the calf, yet for certain reasons of economy and convenience large numbers are annually reared and get scarcely more of their mother's milk than is absolutely necessary to clear out the stomach, and give them a healthy start. When the farmer is so situated as to have a good market for his milk, and a remunerative price for it, he is tempted to sell the greater portion; and if at the same time he is desirous of rearing a good many calves, he finds his ingenuity taxed to procure suitable substitutes for their natural food which he has otherwise disposed of. Oatmeal, linseed and Indian meals are excellent aids, boiled and mixed with a little milk, and when given plentifully, good, useful, hardy, and healthy cattle can be raised with comparatively little trouble. Infusions of hay and gelatinous mosses are sometimes used in rearing calves; but they do not contain sufficient nourishment, are too sloppy, and the calves grow up deficient in bone, pot-bellied, and generally unthrifty. In butter dairies the pure skim-milk without any mixture whatever is the food of the calves, and when given in sufficient quantity answers the purpose admirably, strong healthy beasts of good bone being thus raised. They seem to relish the milk better, and thrive faster when the milk is supplied to them after having become coagulated, than when given merely sour, but not thick. Notwithstanding the efficiency of these substitutes for the genuine article, and the amount of success attending their use, the animals cannot be brought to the same perfection or to such early maturity at full prices, as is the case when the milk is used fresh from the cow. So true is this, that it may be fairly conceded that when the breed is valuable, and early maturity for the butchers a leading object, the full amount of profit obtainable from the stock cannot be reached when the calves are not wholly reared on new milk. A familiar example of its forcing powers is to be met with at every agricultural show, where shorthorns occupy a prominent position, the class of yearlings being so well-grown and their shapes so fully developed as to present all the appearance of mature cattle, while their condition is such that they are fit for the shambles. We have seldom so fully realised the striking effects of pure milk fresh from the cow in feeding calves, and the ultimate advantage to the stock thus reared, in elegance of contour, aptitude for feeding, and general hardness of constitution, as we did in one particular instance, when on a visit to Scotland in the autumn of 1865. In the districts we visited, comprising portions of four counties—viz., Stirling, Lanark, Renfrew, and Dumbarton—the dairy takes a leading position on most farms; and, stimulated by the constant demand for its produce, the farmers are unremitting in their efforts to keep up the supply of milk with regularity throughout the year. The Ayrshire breed is very generally diffused over these counties, no other being valued for the dairy; and, accustomed as we have always been to Shorthorns and Short-horn crosses, the calves we there saw looked singularly diminutive. On hearing the good qualities of the breed from which they were descended described by their owners, and a high value set upon the little creatures themselves, we found considerable difficulty in appreciating their qualities and value—in fact, could not do so until taken to the byre at milking.

time, and shown by ocular and unmistakable demonstration that a little cow, with udder so near the ground that there was barely room for the milking-pail, could give such an overflowing quantity of milk as to render her valuable for that quality alone, independent of all other considerations. Although the size of the Ayrshire breed, whatever the age, sex, or condition, seemed to us remarkably small, still it was not so in every instance, as on one farm in Dumbartonshire, which we visited, we were particularly struck with the large size and general sappiness of all the cattle on it, in comparison with those of other districts which we had previously passed through. Seeing that they were all of the pure Ayrshire type, we asked the tenant why there was such a difference? He replied that it was solely the result of liberal treatment during the first four months of their existence, as he made a point of looking after his calves himself, and gave them new milk, without the slightest adulteration or admixture, for the above-mentioned period. New milk there brings, on the average of the year, tenpence the imperial gallon; and when it pays in the end to give it to calves, when such a price can be had, surely it would doubly repay those to do so, who, living in remote districts, can perhaps only make a little more than half that price for their milk. We have seldom enjoyed a day with more intense enthusiasm than that spent on this farm, in the society of its occupier, and still look back upon it as a green spot in what was altogether a most pleasant and gratifying trip. Situated in the midst of a beautifully-cultivated district on the northern shore of the Frith of Clyde, with much to instruct the mind in an agricultural point of view, there was also much to delight the eye as it roamed over the horizon. Underneath flowed the classic Clyde, bearing on its placid bosom a numerous fleet of ships of all sizes, from the princely merchantman down to the crowded river-steamer and the Highland wherry. Quite in view was the ancient Castle of Dumbarton, celebrated in old historic records as the scene of brave deeds, and mayhap cruel ones also. Through the populous and busy Vale of Leven, the little river immortalized by Smollett can be seen threading its silvery course on to where it mingles with the Clyde. Northwards the lofty Ben Lomond is plainly seen bounding the view, rearing his even-then snow-capped head in undisputed possession of a vast but solitary territory. The calves however reared are at the age of four months able to find a subsistence for themselves when turned out on the pastures, and to enable them to continue progressing in growth and healthy condition require good grass and a plentiful supply of water. Abundance of food should be the motto of every stock-holder, and that during every season of the year; and on no account should he permit an interval of scarcity to occur when changed from the milk to other feeding, or at the close of the season when the pastures begin to fail. The mistake of leaving all animals too long on the grass before removing them to their winter quarters is too frequently made, and is the cause of great loss both of money and time, it being a considerable period before they regain their previous condition. The mistake is mostly made from the desire to economize the winter store of food by not beginning on it too early—an excellent motive, but no cause for any dread of the early exhaustion of the winter store should ever exist, at least under ordinary circumstances. Either a sufficient supply of winter food should be grown or the stock reduced at the beginning of winter to such a number

as there is a reasonable prospect of being able to feed, as one well-nourished animal will leave more profit for the winter's keep than three which have been pinched, it being quite problematical whether *they* will leave even any profit at all. With regard to shelter and accommodation during winter, the straw-yard is undoubtedly the best mode of keeping them in health, as the sheds that surround it afford ample protection from inclement weather, and, being loose and having considerable space to walk about, sufficient exercise is taken to preserve young stock in a growing state. Keeping cattle in warm houses at night, and turning them out during the day on the pastures through all the months of winter, is a practice one would think quite inconsistent with the teachings of reason and common-sense, and certainly quite incompatible with successful and profitable management. It is a system however which is very much acted on, and, notwithstanding improved modes of management becoming better known, seems, whatever the reason, by no means to be on the decline. Every farm-yard should be provided with a large straw-court, shedded, and constantly supplied with water; the expense of putting it up is well repaid by the increased amount of manure made, the improvement on the pastures when not poached and eaten too bare, and lastly the increased value of the animals, without the slightest extra expenditure for food. When cattle are being tied-up for fattening, the arrangement should admit of their having plenty of room; they look better when not too crowded, they can lie in any position, and are therefore more comfortable and can be better managed in every way. It is equally important that dairy-cows should have plenty of room, as it enables the milking to be performed without danger or inconvenience, and obviates all danger of injury from the cows treading on each other when turning quickly round—a mishap which is just as likely as not to occur on a pap or portion of the udder as on any less sensitive part. Proper shelter, so that they are protected from the chilling rains and cutting blasts of winter, a regular supply of pure water, good and sufficient litter, and an abundance of wholesome food, not only keep the cattle in a continual state of progression, but ward off all those diseases which are the result of chills or sudden changes from scarcity of food to great plenty. Losses from these causes are excessively grievous, and can seldom be prevented by medicine, as the poor animals are usually so far gone when first noticed that before any evacuant within reach of the farmer has time to act on the peculiarly complicated system of stomachs possessed by the ruminants the vital spark has fled. Selling the most valuable animals each year for the sake of the slightly-increased amount of receipts, is a prolific source of injury, and keeps many a herd of cattle at a point almost below mediocrity, that would under happier auspices be a credit to its owner and much more profitable. We do not, of course, allude to wealthy stock-owners, who never sell from necessity; but to those who, living solely on the profits of their farms, are compelled by the inexorable force of circumstances to act in the way that will realize most money for the time being, without being in a position to consult their own wishes in the matter. If at all possible, a few of the choice young heifers should be held over each year as breeders, so that there may be no danger of retrogression in the character and quality of the stock.

J. S.

## THE OLD PLANS OF IRRIGATION.

At one time the irrigation or watering of land was more common than it is at the present day; and on hilly lands having a command of water the practice was more general than in comparatively level champaign districts. The rule was almost universal that where there was a command of water and means for application it was applied on the land. Towards the middle and close of the last century, when farms began to be regularly cropped under the alternate system of husbandry, as it is sometimes technically termed, the practice was greatly curtailed, and in many instances wholly given up. It was applied not only to land permanently lying in grass,

but also to arable lands when in grass. In those simple times arable lands were cropped on the out-field and in-field system, and it was to the out-field that the water was applied. The in-field lands were kept under a continuous course of cropping, and to them all the manure made on the farm was applied. The out-field lands were cropped so long as they would yield anything that would pay the harvesting; and when they would yield corn no longer, the grasses having got the mastery, it was then allowed to lie in grass; and it was when thus laid out that the water was applied to restore the worn-out soil to renewed fertility. Not long before the father of the writer entered upon

farming (1806), about half the lands under the plough were out-field, and thus cropped. And when serving his apprenticeship the writer himself assisted in filling up some of the water-courses, so as to bring the land they occupied under the plough.

Such being the old practice, it forms a prominent topic in works on agriculture, published at the time. It is noticed in most of the country reports to the Board of Agriculture; and in his surveys and work on "Landed Property," Marshall gives a detailed account of it.

In the latter work, Marshall gives illustrated directions for watering land, on the following four plans, viz. :—

- "1. Covering low flat lands with stagnant or slowly-moving water.
- "2. Raising flat lands into ridges, and overflowing them with running water.
- "3. Spreading running water over naturally uneven surfaces, and
- "4. Watering sloping grounds that have been raised into ridges by cultivation."

(1). In the first of these plans a dam or sluice was placed in the river, so as to raise the water sufficiently high to flood the meadow lands adjoining. In such cases the nature of the details depended much upon the inclination and character of the land. Thus, the lands immediately adjoining rivers are often higher than those more remote, so that by an underground pipe or conduit, the latter would be more easily watered than the former. Floodgates were placed upon these underground pipes, so that they could be opened and shut at pleasure as the work or state of the grass required. Again, underground drains were often required to draw off the water, so as to prevent too great a depth when stagnant, and to dry the ground when the water was turned off the main altogether. In other examples, the application of the water and its removal from the land was in each case effected by open water-courses. But the more common plan was partly by underground and partly by surface conveyance of water to and from the land.

But, besides watercourses for conveying the water to the land, the land itself generally required less or more levelling before the water could be spread over it, according to this plan; and to effect an even distribution, it was often necessary to plot out the ground into a series of levels, or rather gentle inclinations, in size according to the undulations of the surface, not unlike laying out ground for rice-beds. In many cases this subdivision of the land was surrounded with no little difficulty; for, unless the levels were mostly formed by the hand of Nature, the equal distribution of the water on the lands was more easily effected by the second method of application noticed by Marshall—viz., ridges.

(2). The soil dug out of the feeders and drains was not unfrequently found sufficient to form comparatively level land into ridges; so that this plan of spreading the water was less expensive than is perhaps generally imagined. Thus, when the land was previously under aration, it was gathered up by the plough into ridges of from 30 to 60 feet in breadth. An open cut was then dug down the middle or crown, for the feeder, and which, from its being nearly level, was not unlike a canal when overflowing its banks. The open furrow between was formed into a drain, and the ridges levelled, or rather carried into the proper slope by levelling machines, and harrowing and finishing off by manual labour. When in grass the grassy sod dug out of the middle of the ridges was placed upon the edge, so as to raise the surface several inches higher than before in the middle of the ridge. The grassy sod from the drain was placed beside this, and the loose earth dug out from both spread over the surface so as to give it the proper inclination. In many cases this was all that was required to prepare the land for the water; for, owing to its being comparatively level, the feeder when full overflowed like a canal, spreading the water equally over the sides of the ridges, and as the sides of the ridges were lowest at the edge of the drain, there would be a gently-continued imperceptible flow from the feeder to the drain. Through hollows a foot and even two feet below the natural level, the water in the feeders was sometimes carried by small embankments, sometimes in aqueducts over the drains, where such were carried down these hollows to the end or side ditches, and so on. But raised aqueducts and embank-

ments were avoided as much as possible, under-ground pipes being preferred for conveying the water from the level on one side of a hollow to the same level on the opposite side, such being out of the way of the feet of cattle, &c.

In examples of this kind the cardinal rule was to avoid stagnant water anywhere on the side of the ridges. The nearer to equality of inclination and uniformity of flow from the feeders downwards to the drain the better, as this produced an equal fertilising effect upon the land. But an equal inclination could not always be made; indeed, it was but seldom made; hence the other maxim of an equal quantity of water to an equal area of land or length of ridge in equal times.

(3). The third method, viz., spreading running water equally over the surface of a meadow without ridges, had the same object in view as the second, the surface of the meadow being undulated or uneven. The general practice of carrying out this plan involved a considerable amount of underground work in the conveyance of water to the higher levels, where it was thrown upon the meadow, and allowed to spread around over the greatest possible area of land by gravitation. To effect this, and avoid rapid currents, small wooden troughs lying on the surface were used. And to avoid expense this gave rise to the finishing of one part of a field at a time, the wooden troughs being then removed to another part. In this way an old man or boy went over a larger area of ground in a given time than those unacquainted with the practice were apt to calculate. Another plan of distributing the water over unlevel surfaces was by crooked feeders, winding round about the grounds on levels, subsidiary feeders branching off from these, on what was termed, in some places, the "fish-bone system." This plan as illustrated in agricultural books is generally too formal, the meandering of the feeders having too great a sameness of curvature to each other. Whereas, in the meadow, although the branches have a close fish-bone similarity, the diversity in the direction of the principal feeders was greater than is represented in the old works just referred to.

(4). The fourth system noticed by Marshall, of watering sloping ground that had been raised into ridges by cultivation, was perhaps the more common. In ploughing, the land was gathered up into broad, high-crowned ridges, and carefully kept in this form. The ridges thus formed and kept were often very crooked, the surface of the ground imperatively demanding it; and they were not always of uniform breadth, being narrow in some parts and broad in others. When in grass and about to be watered, a plough-furrow was opened down the crown of each ridge, into which the water was then thrown from the main water-course at the headlands. The sod turned out by the plough was cut into short lengths, and used for making dams and directing the water over the sides of the ridges, and the surplus from one dam to the next below, until the whole was utilized. The greater the inclination of the land the greater the number of dams required and the less the distance between them, the object of the dams being not only to turn a portion of the water over the ridge, but also to prevent the remainder from forming a rapid current, and thus washing away the soil. When the ridges were of considerable length and breadth, it required a corresponding volume of water to be turned down each ridge, and no little skill was requisite to spread it equally over the whole, from the upper to the lower end. With a plentiful supply of water a number of ridges could be watered together; but when the supply was limited, only two or three, and sometimes not more than one ridge at a time. The ridges on the farm already referred to, first occupied by the writer's father (1806), were about half-a-chain in width and from ten to twelve chains in length, so that each ridge contained upwards of half-an-acre; and to this day the water-courses and form of the broad crooked ridges may be traced on the outfield lands thus watered.

The water-courses in some porous gravelly and sandy soils had to be puddled in the bottom and sides with clay, or with a mixture of clay and peat, to prevent the water sinking and flowing off through the subsoil. In the course of time such soils filled up with vegetable matter, and sometimes with clay and silt, purposely mixed in the water, thus filling them up and changing their texture from gravel and sand to loams.

## THE NEW FARM.

"Painless dentistry," did you say the advertisement was? Why, then, now, that's just exactly what I wanted last Christmas, and expect to want about Midsummer-day. Now, is there no one of the many existent good-natured fellows who will not, as poor inimitable Wright used to say, "come for to go for to send for to fetch for to bring for to carry" one of these said clever artists to sustain me under the operation of "draw" to which I shall shortly be subjected. I should be so thankful if it could be done. How thankful I cannot say.

Having touched upon the subject, let me go farther and counsel, I trust without offence, enthusiastic youth. I am spirited thereto by a recent encounter, from which I have emerged I consider not only scathless, but triumphant, with an unconscionable tradesman who had the audacity to try upon me a trick which I can attribute only to what they must have judged a juvenile guilelessness of countenance.

Don't you, my lad, if you go into a swell London shop (whether to fit out your bridal, or in any such bashful mood), on giving an order, content yourself with simply entering in your pocket-book the price stated by the airy and self-satisfied individual who shall accompany you through the show-rooms, giving the prices so fluently after rapid calculation with pen from behind his sapient ear. Get the particulars written out of each article that you order, the price it shall be for cash upon delivery, and the time of its certain delivery. To that document get your fashionable attendant's signature appended, "Catchem and Co., per Oily Wideawake," or else the chances are that upon receipt of the goods you will receive also an exceedingly spiced invoice, far hotter than you intended, and which shall curtail you of some reasonable comforts for months to come; while if you go open-mouthed to your solicitor, and mean to blow them up bodily, you will find that there is no *locus standi*. They will shield themselves under the simple reply, "We gave only a proximate estimate." So you, my dear, will be beautifully done. *Experto crede!*

I am more urgent upon this point, as there is a noble trustfulness about the mind of youth, which is most admirable and highly romantic, but simply doesn't pay. For many a year how have not we old fellows been prone to half-apologize if we had dared to ask whether "discount were allowed;" "if such be the cash price;" "whether it were of the material," and so on. And it is with something of an angry rebound of feeling that one triumphantly demands now from the most self-possessed shopman "the best material for the lowest figure; and be quick, please, for I'm in a hurry."

No more of the diffidence with which we took our orders as to breakfast, &c., from the college scout, and allowed his intervention with the awful University tradesmen. No more of that: "no, no, not for Joe—not for Joseph, oh! dear, no!" Eh! the smiling of the counter-skipper now, and the bowing, and the desire to serve, and the hope that you'll recommend us, sir," which, to the vain mind, are of value equal to a redoubled discount.

Smart's the word. Knock the wind out of them first blow—apologizing, of course, for the *contretemps*; but the effects produced, and the courteous apology, effectually salves.

Water-wolves—water-wolves are we not all? preying upon each other, rather than "jolly dogs," as one fain might wish, and as we were wont once to believe, over

devil'd kidneys and a damper, "in the days that we were young, a long time ago."

D'ye see that, young friend; for if ye don't, and have to wait for the spectacles of personal experience, why, then, more's the pity, and our Cassandra self hath sung in vain.

But to return homewards. I was constrained just now to steep my hands, feverish from rowing, in a basin of water half-boiling. I had been musing of Shorthorns, and the sweet, darling heifer-calves that have been dropping upon our pastures of late, when, drop! down came a huge spider from his swing, which I had not noticed above me. Poor thing! how he was doubled up at once! Didn't like hot water at all. Must have been married. It was so like what one is obliged so often to do oneself, under influence of the conjugal (tin) kettle.

There hath been a multitude of the spider-tribe about the house lately. They are said to follow in the wake of the black beetles, a huge horde of which has overrun us again lately. The beetle must afford rich feeding; for these spiders are a monstrous sort. We have found that strewing the leaves of the elder-tree upon the kitchen-floor causes somehow a diminution of the beetle class. Whether they find the vegetable poisonous or not, I don't know. A confectioner counselled the recipe.

We are plagued by another insect invasion. The evening air hisses with the flight of myriad cockchafers. Herein, however, our old friends the rooks (to whom we have been staunch, under the remonstrance of prejudiced agricultural neighbours) have done us an exceeding service. I could not imagine, yesterday morning, whatever was the matter with the birds. They were in and out among the apple-trees and beeches, clumsily alighting, and staggering along the weak twigs, managing to maintain their equilibrium only by a half-flutter, with their wings up, and swaying after the example of Blondin's pole.

"Them be after the blight, them be," remarked fat Melon, the gardener, as he came up to my window, triumphantly exhibiting a grand Gloire de Dijon rose: "Beaut he a beauty, sir?"

"Call him the 'Second of May,' Melon, if you want a name for it."

"Why, sir?"

"Why, because it reminds me of some one whom I saw on that day with his shirt-collar petals all turned down, and a yellowish tinge about the gills."

Poor Melon, who likes a dance about the May-pole, and a suck at the cider-cask afterwards, hereupon retired in consternation.

"Them be after the blight, sir." And, sure enough, they were in good earnest. I at once had the craws of sundry rooklings (of which a tart was being made for the kitchen) cut open, and found therein a thick débris of the comminuted, half-digested pest, a few of their shiny brown armour-plates being yet unsmashed, which I exhibited in exaggerated stature, by help of the microscope, to our horrified cook.

Bless her heart! she is a good, clean, simple-minded thing. But the mention of her name reminds me. She of late has heard a ghost! In the stillness of the night, a knocking at the door! Too frightened to move, she has simply ducked under the blankets, instead of advancing, as we consider she should have done, interrogating, "Who's dat knocking at the door?" (Aside:

"Dat you, Sambo?" to be omitted.) Well, of course, this is no joke in a country-house. The place soon got the reputation of being haunted; and then there's no getting servants at all. Well, it so happened that, one night, ourself had got deeply interested in a hideous novel—one of the "Fine Young English Gentleman" sort, that are as keenly rapid in their attractiveness ("sensational effect," it is termed) as a red-herring drag, but which no one ever looks at a second time, for the pleasure of restudying a pet passage of eloquent and truthful worth (as one does with the Waverley lot), and which are only so much "rot," to use an expressive vulgar term, when the literary merits of England come to be registered—when, about the witching hour of midnight, we heard a mysterious "Tap, tap! rap! tap, tap!" It made our blood run cold, we confess; but we were brave enough to explore, and we found—what, I wonder? Well, I'd have told you, friend.

Heresy and insubordination in the camp! "You must indeed tell us when the calf is going to be killed, poor dear little thing. It is so tame and so pretty," with an air of coy indignation our eldest born little girl remonstrated, sitting up in her cot, as I went to give her the regular good-night kiss. "Such a sweet," coaxingly added another little puss, also leaning out from behind her curtain with a remonstrativeness of pouted lip that was pretty to behold. "I declare I won't touch veal for ever so long," said her sister in chorus. This was all in reference to a fawn-tinted gazelle-eyed Alderney calf that was unfortunately born of the masculine gender, and had consequently to make way for cream and butter. As if they hadn't quite enough of pets already! enough forsooth to ruin any farmer. There's the old faithful canter-on-three-legs Breadalbane terrier, with three fat long-tailed puppies in her wake, as slow-paced as herself. There are no end of bantams, although ultimately I had to send all the poultry from the stable premises to the bailiff's wife at the farm, as the poor hens prone to incubation had been frequently left to their fruitless sitting without ever an egg under them, until it was difficult to say which were the barest, their hapless bosom or the board that served them in lieu of nest. Talk of the discomfort and attaching agonies of a seat in Parliament; they are for not a moment to be compared to the occasional sufferings of a brooding fowl in a child's hen-house! Then on the list of pets come cats and kittens in hopeless measure. Woe betide either them or the young pheasants are long! A curious incident happened to this special nursery puss last week. She had had left to her one prettily-marked bantling out of the lot born and duly consigned to a watery grave, and of this she was especially proud. Well, one day it was missing, and the poor mother was miserable. The children declared that she had forgotten where she had deposited it. This seemed an extraordinary theory, considering the might of instinct. Anyhow she followed them everywhere in their search about the rooms of the house, the out-buildings, and even through the shrubberies and woodland walks, all to no purpose, mewing piteously the while—whether a note of lamentation, or gratitude, or entreaty, it is impossible to say. At last they appropriated a kitten from a cat at the farm, which with much ceremony they delivered to the nursery puss. She at once took to it, while the robbery or transference was treated with the utmost indifference by the bcolic puss, who trotted about or watched in the stable and cowsheds for her prey just as unconcernedly as if she felt that all had been done for the best, and that her offspring had been fortunate in its promotion to an upper circle.

Well, one morning, about light, some days after the kitten's disappearance, I was awoke by a sad cry, as if of an animal in pain, which seemed at one time quite near,

at another quite far off. It occurred to me that it might be that old Melon had managed to ensnare a rabbit, of whose inroads he has been complaining lately, and that it was from this unhappy animal that the wailing proceeded. I looked out of the window, but failed to detect the victim's whereabouts. Then the agonized cry drew nearer, until at last it was beside my pillow. I sprang up, and in a closet behind a chest there was the wretched missing kitten, crawling and shrieking as if mad with pain. It must have been there for some days the housemaid declares, and that without making the least sound of any sort. How to account for the circumstance is beyond me, unless possibly it had been in a trance. Anyhow, so it occurred. The nursery puss was delighted to receive her own again from the children, with sundry scoldings to boot, while the farm cat took ungraciously the return of her infant, which our fry decided it was only just to restore.

Rooklings, tom-tits, sparrows, and such like, they have had in quantities, and destroyed by excess of kindness, too, feeding them by force ever so often in the day. Lastly, they have some blackfaced mountain ewe-lambs within a wired enclosure. This last sort doesn't pay on my side. It's all very well for the young ladies to have a snowy pet, with broad blue ribbon around its neck, nibbling parsley out of their hands, and bleating gratefully at their approach. But when these said lambs grow to be big sheep, and in their turn have lambs too, then it comes to be no joke, for me at least, the fond feeder of the lot ovine and human, for it just happens that their pet lambs of the year before last have this year lambs of their own, which are now worth, the chicks hear from the bailiff, some fifteen shillings a-piece. For this sum they have deliberately sued me. Now if this goes on it must ultimately be a serious affair. "What about their keep, my pet?" I appeal in vain. "Oh! you know, papa, they can't eat much," &c., &c. But the subject depresses.

To change the subject: In the river bed below the farm, there is lodged a huge boulder, some five yards square, which when under water is, as the Irishman said, a sign to the traveller that he must not attempt that ford. It is a splendid balcony this hot weather, whereon one can lie wandering in dream-land, soothed, too, as Mæcenas, by the murmur of the flowing stream.

The other day we saw a splash from the shore; so getting into the boat, we ascended the rock upon the upper side, and creeping quietly to the edge, on looking over we saw beneath us a glorious salmon of about ten pounds weight, resting on its oars, upon the look out for spoil. Dash! flop! and having secured the prey, with a quick, brief, curve in the flashing water, he was returning to his post when his quick eye marked us, and with a glance of light through the wave he was gone!

What a blessed gift is Sabbath repose! For the fashionable idler it is an idea difficult to realize; rather, in fact, ennuye, tired, tiresome, he wanders from club to club, acquaintance to acquaintance, to the stables, to dinner, to early bed. The right welcome bright enjoyment it really is, fully to appreciate, take a mastership in a school for six months. Teach boys from half-past six a.m. to ten p.m., with rare intervals, when the small deer have their play, and are really more troublesome than while under lesson drill, owing to the scrapes they will get into, their noise, their pugnaciousness, their dirt-pie delight. Eh! what it was then, to sleep the extra two sweet hours undisturbed by that dreadful bell! But why particularly I dilate upon Sabbath repose here is that one enjoys it so thoroughly of a summer evening at one particular corner of the sloping lawn, just where it joins on to a wild piece of the hill. All nature seems to appreciate the difference in the day. The whole air is so still and warm, and the tints upon the western sky are so delicious.

The swallows skim fearlessly and frequent in the upper-cloud region. A bright brown hawk slips idly across. Abundant turtle-doves croon amidst the elm-trees. The wild pigeons are cooing through the wood. The incessant rooks are so busy on their tree-tops. An occasional pheasant steps gallantly out from the covert shelter, occasionally escorting a timid hen who has been up to feed, and seems fearful of returning alone; while a brace of partridges advance, pecking up to the very verge of our feet, where we lie unseen, young and old holding our very breath, lest we should disturb the elements of our enjoyment.

We have had a good deal of trouble with the shorthorns of late. "Well! and what is it has happened to your fascinating stock?" some may ask. Why, in the first place the grand cavalier the monarch Butterfly having managed by dint of his great weight and his being tied up to establish a housemaid's knee, it was judged expedient to remove him into a loose box. As it happened, fortunately, the place selected was the bay of a disused barn, where he was strongly walled in on every side, excepting the door, which he makes to creak and shake every time he touches it with neck or flank. Precautions had been taken in the fitting of it, that he should not be able to introduce his horn anywhere. As his temper is not of the best, and his eyeballs glare out exactly like those of his grandsire the Towneley Frederic, I judged it expedient to attach a cord to the ring in his nose, to run over a small wheel on the beam above, being weighted at the end, so as to allow of his advancing and retiring at pleasure to and from his

manger. This was a large stone trough laid upon a bed of masonry. The very moment he found himself at liberty he worked his horns beneath the trough, and threw it high in air with inconceivable strength and savage temper. Down it came again, and right upon the cord, pinning his nose to the ground; whereupon he blared and roared so fearfully that his attendant, in a fright, managed to cut him loose and get out again in time to avoid his resentment. Here, then, was a pretty kettle of fish! For the time, he went positively mad. It was frightful to behold his fury as he wreaked it upon everything within reach. Fortunately there was little besides his bedding and his victuals attainable. He had to be watched continuously, for fear he might manage to overthrow the door; but in a day or two he grew calmer, as he got more used to his lodgings; and, stealing his opportunity, the herd-boy, having left the door so far open as to allow of his hasty retreat in case of need, managed to pounce upon the animal's tail, to which he clung vigorously, until the beast, having exhausted himself in the vain endeavour to get free, took a look round of curious inspection; whereupon the lad hooked him cleverly with his rod, and the bovine brute was at man's mercy again. He became mild enough on being tied, and I trust now will not have to be done for with a bullet, as I once was afraid. What other events in the herd have occurred I must leave until next time.

I forgot to mention that the ghost turned out to be, as you may have guessed, simply a death-watch beetle.

VIGIL.

## AGRICULTURE OF FRANCE.

A couple of years ago there went up such a cry from the French agriculturists that the Government felt it incumbent to appoint commissions of enquiry. The country was divided into thirty zones, and each zone was subjected to the examination of a different commission. The enquiry has terminated, and an immense mass of evidence has been sent to the Minister of Agriculture. Several volumes have already been published, and the information furnished by these printed reports is quite sufficient to show the causes of suffering. These are want of labour, want of capital, want of communication, want of instruction, and the taxes levied on the transfer of property. To this list may be added the sub-division of land; but most of the commissions, though they point out evils attendant on this system, consider it favourable to production. The second question put by the Minister of Agriculture runs thus:—During the last thirty years what influence has been exercised on the conditions of production by the division of property? The commission for the department of the Manche says the result has been to augment production, but in reply to other questions the same commission points out that the small proprietors have not sufficient capital to improve their farms; that the excessive division of property is an obstacle to the employment of machinery, and again that the principal objection to the division of property is that it renders drainage impossible. The Calvados commission also replies to question two, that the division of property has augmented production, but deplors the want of capital. In Eure, sub-division has been found prejudicial to production, and the commission condemns the practice of dividing the land amongst the heirs on the death of the head of the family. M. Genteur, president of the 11th zone, gives much valuable information in his report. He says that since 1789 the division of land has constantly progressed, and that, confined within reasonable limits, this system presents two advantages—1st. It is useful as regards the development of production; 2nd, in encouraging the labouring classes to buy property it "moralises" them, interests them in the maintenance of social order, inspires them with conservative sentiments, and keeps them from the temptations and seductions of the town. On the contrary, when

exaggerated it gives rise to serious inconvenience, and the Legislature should prevent it being carried to excess. According to the Code Napoleon, the father, when dividing his goods amongst his children, is obliged to give each an equal share of all the objects composing his fortune. The opinion of the agricultural world is that this law produces an excessive division of landed property, and that it would be better for the father to share his goods amongst his children according to their tastes and professions. Another commission reports that "the extreme division of property is one of the principal causes which prevents the use of agricultural machines." And again, when alluding to drainage, "the parcelling out of the land prevents the farmers carrying away the water." The Commissioners admit that the system of division should end somewhere, but it would be a terrible blow to the ideas of 1789 to re-establish the laws of primogeniture even as regards land, and no one would be bold enough to propose such a measure. M. Genteur does go so far as to recommend that the head of the family should be allowed to give his land to one child and his funded property to another; but any bill introduced into the Corps Legislatif tending to such a consummation would be vigorously opposed.

Another cause of agricultural suffering is the want of labour felt all through the country; this is attributed to the army, the development given to various industrial undertakings, and the immense public works being carried on in Paris and other large towns. Everywhere statistics show that the rural population is on the decrease, and that the deaths exceed the births; the peasant prefers the town because the labour is generally lighter, more continuous, and better paid; in fact, one can easily imagine the attraction for a Breton, who gets at most half a franc a day, of ten times that amount to be earned in Paris under Prefect Haussmann. That deaths should nearly everywhere in the country exceed births does not alone depend upon emigration. If we turn to another report, we find that immorality has much to do with the matter, and that there is a general hankering after luxury:—

"The good old manners are disappearing day by day, and rustic simplicity is no longer in vogue; luxury and the love of

pleasure have invaded the most remote parishes. The number of natural children increases, the number of legitimate ones diminishes. The peasant of to-day is determined not to have children. To counteract this tendency it is demanded that the Government should encourage large families by relieving them from taxation. I am obliged to state that religion is on the wane. The priests are worthy of all respect, but they have lost their influence, and, to believe the testimony of many persons, this state of things has been produced in consequence of the clergy preaching dogma rather than morality, and not adhering to those principles upon which modern society reposes.

Want of capital is another malady which afflicts agriculture. The fever of speculation has spread through the whole country, and the money which used to be laid out in the improvement of land is now invested in railway shares and loans, or squandered on the Bourse. On the other hand, the farmer who desires to get money can only do so by paying an exorbitant

interest, for very few proprietors can fulfil the conditions upon which alone the *Crédit Foncier* and *Crédit Agricole* will make advances. The country people also complain of the large amount of stamp duty which they have to pay, and where there are so many forced sales, and where so many persons are left land which they cannot keep, this species of taxation is especially onerous.

What most of the commissioners demand is that the conscripts not belonging to the active army shall only be called out for drill when there is no agricultural work to do; that there shall be fewer fairs and market days, where much time is wasted; that the stamp duties shall be lowered; that the farmer shall be afforded facilities for getting money; that agricultural instruction shall be given; that some means shall be adopted to prevent the constant emigration to large towns and some modification introduced into the present law affecting the right of disposing of property by will.—*Pall Mall Gazette*.

## THE EXHAUSTION OF THE SOIL, AND THE RENEWAL OF ITS FERTILITY.

The following paper was read by Mr. J. J. MEECH, at a meeting of the Midland Counties Farmers' Club, at Birmingham, on Thursday last, June 4. Twenty-one years ago, I came on a visit to that eminent man, your near neighbour, the late Sir Robert Peel, who was himself, even then, a great agricultural improver, and deeply impressed with the necessity for amending our agricultural ways. My speech on that occasion is recorded in my book. I well remember the celebrated "Tanworth bull" being led out for our inspection, and I have no doubt that he has left reminiscences profitable to the neighbourhood. By your invitation to me to come here to-day I take it for granted that, as agriculturists, you are dissatisfied with things as they are, and are resolved upon further progress. I have great faith in your determination in this respect, for I cannot forget the very recent beginning of your now great Birmingham Show, and how rapid and successful has been its development. This, alone, convinces me that there must be among you some bright agricultural spirits. I remember dining at its inaugural meeting and subscribing to its funds. But while your busy Birmingham hive can supply Britain and the world abundantly with its wares, you fail to meet the food requirements of your neighbourhood. Why is it that we cannot produce our own food in sufficient quantity? I have proved by my own farm, and by my uncontradicted statements, that we can more than do this, by the investment of greater intelligence and capital. But to do this we must add science to art, and learn to believe in science as our profitable helpmate. That has been for 28 years the opinion of the Royal Agricultural Society of England, for as I opened its annual volume I saw on the title-page "Practice with Science," and I accepted the motto in its full significance, because I saw on its council your talented countyman—the author of "Talpa"—and others whom I knew could fully appreciate the meaning of that motto. But is that title recognised and acted upon by the bulk of British agriculturists? I feel humiliated in being obliged to say, decidedly not. What does Baron Liebig say of this in the preface to his last great work, "The Natural Laws of Husbandry," published in 1863? "In the sixteen years which have intervened between this work and the sixth edition of my 'Chemistry applied to Agriculture and Physiology,' I have had sufficient opportunity to become acquainted with all the obstacles which are opposed to the introduction of scientific teaching into the domain of practical agriculture. Among the chief of these may be reckoned the complete separation which has always existed between science and practice." What do I often read in the British farmers' own papers, and what do I too frequently hear from farmers themselves? "None of your theory and book-farming for me: I am a practical man." But I am happy to be able to admit that the last twenty years have made some considerable inroad upon this feeling, and that there is growing, especially among the rising and better-educated generation, a gradual but still too limited tendency to believe that science may hereafter be found to lend useful aid in the cheaper and more abundant production of food for the people. Let me say for myself that

I am a book farmer; that for more than a quarter of a century I have practised by the light of science; that I have read and studied the communications of eminent chemists and agriculturists who have thought it no disgrace to put into print their discoveries and experience. What benefits have not such men conferred! Long after they shall have passed away their knowledge will remain to enlighten and advantage their fellow-creatures. I am a firm believer in the theories and principles of that great man Baron Liebig. But can we wonder that the agricultural mind has been so cramped and narrowed, when we reflect that it was only the other day, in the history of our nation, when we had no roads, or such bad ones as to be hardly available, so that the agriculturist was, as it were, locked up in his own parish, without educational resources or means of intercommunication, and, therefore, as a natural consequence, largely impressed with the self-sufficiency of isolation? But the schoolmaster is abroad now: the steam-kettle has set everything boiling, and we are preparing to advance at steam pace. The mind and body are equally, and, consequently, in rapid movement, and, if I could come again in 1868, with some of my kind, hospitable, and charitable farming friends, and then "take stock" of British agriculture, how greatly should we not be astonished, and hardly believe that we were in the good Old England of the present century! We are all slaves to circumstances, and if I find fault, it is rather with British agriculture than with the British farmer and landowner. Begging pardon for this introductory digression I proceed to the subject of my paper. There is a natural tendency in man to exhaust the soil of its very small percentage of food for plants. This desire is too obvious to be denied, and it has caused the stringent restrictions in leases forbidding the sale of hay, straw, roots, and green crops. Man has to be protected against himself, for he is his own greatest enemy, when he proceeds upon a system of exhaustion without restoration, thus producing minimum instead of maximum crops. This spirit of spoliation arises from a want of knowledge and a mistaken belief, or hope, that there is in the soil an inexhaustible store of plant food. In our colonies and in the United States of America (whose Government has still 1,500,000,000 of acres of uncropped land to dispose of, without any restrictions as to cropping) the first settler finds a soil stored with an ample supply of plant food, which he believes will last for ever, so he goes on cropping and selling everything off his land, making little or no manure, which is either thrown into a river or left unused, and when a gradual but certain exhaustion of the plant-food in the soil has proved to him that his crops are no longer remunerative, he seeks a new home in the unexhausted and unsettled far-west, taking his chance of the fever or ague, generated by rich but undrained and uncultivated swamps, or lands reeking with decomposing vegetable matter. Good farmers in Britain can hardly realize the fact that the extensive and once-fertile original settlements of America have been so exhausted by 80 years of constant cropping without manure that some districts will not grow wheat at all, while

extensive tracts produce only from 8 to 12 bushels per acre, and often less. (See recent American statistics; also Baron Liebig, "Modern Agriculture," p. 220.) The soil is like a school pudding, with a few plums in it, widely and very unequally scattered. Baron Liebig says at p. 143 of his "Modern Agriculture": "Chemical analysis has, with its rigorous methods, proved that of thousands of fields there is scarcely one which contains more than 1 per cent. of the ash constituents of plants (clover, for instance) in a state suitable to the wants of plants." Many fields contain only one-fourth to one-half per cent., some even less: Liebig points out that if this plant-food (phosphate of lime, potash, and ammonia being the principal elements) were intimately intermixed and condensed on each granule of the soil, we should get many and better crops from our present store; but the plant-food is usually not in this desirable condition, and therefore the chemist's analysis of our soil gives us no accurate knowledge of the quantity of plant-food in it in an available condition. The very finely comminuted condition of Peruvian guano causes it to be very quickly used by the fibres of plants, especially when applied with water or washed into the soil by rains. This teaches us the value of an intimate admixture and comminution of the soil. Liebig says: "A field is not exhausted for corn, clover, tobacco, or turnips so long as it yields remunerative crops without needing the replacement of those mineral constituents which have been carried away. It is exhausted from the time that the hand of man is needed to restore the failing conditions of its fertility. In this sense, most of our cultivated fields are exhausted. The soil will be termed exhausted, in the agricultural sense, when the crops cease to be remunerative—that is, do not cover the expense of rent, labour, interest of money, &c." (See Liebig, "Modern Agriculture.") I wish you would read the Baron's lucid and original explanations of many things that now puzzle and perplex the British farmer; for instance, why you can grow barley where you could not grow peas or clover; why bones, superphosphate of lime, nitrate of soda, or salt are very advantageous in some cases and useless in others. He, as it were, takes you down into the soil and shows to you the plant-food, in what condition it is, and how the rootlets feed on it. I come now to consider the means of giving or renewing fertility. Natural or artificial drainage is one of the most important bases of fertility. No one would expect a plant to thrive in a flower-pot if there was not a hole at the bottom for the escape of surplus water. So it is with the soil. The fact appears so clear and indisputable that one would suppose it to be now generally admitted. Perhaps the want of means may prevent much draining, but I know that in my county there are a great many farmers, not deficient in capital, who do not even now believe in drainage on their strong loams (non-calcareous tile earths). Twenty-odd years ago I proved that they were mistaken. We must offer our tribute of thanks in this matter of draining to the late Mr. Smith of Deanston, Mr. Josiah Parkes, and Mr. Bailey Denton. Foremost and earliest in spring draining was the late Mr. Elkington, of your county, who received £500 from Parliament in acknowledgment of the services he had rendered. I drained all my land 24 years ago, making it, as it ought to be, the first step in improvement. Every drain is perfect now. Probably if all the land requiring draining were to be drained, the cost would amount to from £40,000,000 to £100,000,000. Our best authorities agree that it would return 15 per cent. to pay for the 6 per cent. principal and interest of the operation, and it can be done now on security without outlay. There is so much iron in some parts of your county that unless the pipes be small, and the flow consequently rapid, the drains get filled with it. I remember that prevented the success of Mr. Smith, of Deanston, draining for the late Sir Robert Peel. He used the old flat sole, with a tile upon it. In consequence, the flow was wide, thin, and slow, and the ochrey iron matter had time to settle and accumulate. The 1-inch pipes put in by Mr. Josiah Parkes caused a much more rapid flow, so that the ochrey matter was carried out into the open ditches. By very deep draining I have converted a small bog into a sound, dry, profitable soil. I am sorry to see it recorded in the Society's Journal and elsewhere that on some estates it has been found necessary after drainage for the landowner to appoint regular inspectors of the ditches and mouths of outlets of the drains, which would, but for this, be choked up, owing to the neglect of the tenants. This ought to form a stringent clause in the

lease, but I rarely hear of its being inserted. I heard that when parts of Cheshire were drained, and the rushes disappeared, the farmers complained that drainage had spoiled their cheese by doing away with the rushes. The fact is, the milk was so much improved by the new grasses that sprung up that it was too fat, and the cheese would not "travel" safely, but broke into pieces. Some knowing hand remedied this, by skimming a little of the fat or cream off before making the cheese. In Suffolk they make butter first, and then cheese from the skimmed milk. This is called "Suffolk bang." There is no fear of its not travelling safely; for it has been suggested that they should be used for paving stables. It is sold at about 3d. per lb., and is eaten sometimes with the fat of salt pork, to "get it down." I could enlarge very much on the advantages arising from drainage, such as greater and earlier crops, of better quality and easier ploughing, and increased temperature of soil and subsoil; but most of you know all about it. I would not farm undrained heavy land, if offered to me free of rent. How important is tillage! After drainage, and before manure, the most important. Baron Liebig writes (at p. 108 of his "Modern Agriculture"): "As the smallest portions of (plant) food cannot of themselves leave the spot in which they are held firmly fixed by the soil, we can understand what immense influence must be exerted on its fertility by its careful mechanical division and thorough intermixture. This is the greatest of all the difficulties which the agriculturist has to overcome." This indicates the importance of first-class implements in perfect condition, instead of the imperfect, old-fashioned, and half-worn ones which we too frequently see. Tillage acts in various ways, as beautifully explained by Liebig. If we could see the half per cent. of available plant-food in the soil, we should find it widely scattered, unequally apportioned, and insufficiently diffused—more in one place, less in another; and as water cannot transpire it from one place to another, this must be done principally by cultivation. One cannot sufficiently appreciate the advantage of keeping the surface of our hard or stiff soils open and friable, thus permitting the operation of those natural laws so lucidly explained by Liebig ("Modern Agriculture," p. 49). After the crop is removed, the soil is usually tied together by root-fibres. It becomes of the highest importance that they should be well shaken out by cultivation, and thus easily decomposed by atmospheric action. I have found by practice the advantage of cross-ploughing my clover-leas before they are ploughed again for wheat. It makes a considerable difference in the crop, and gets rid of slag and wireworm. I know many who do this, although the general opinion has been for only once ploughing; but it is erroneous, at all events on such soil as mine. Try an acre or two; and you will soon arrive at a conclusion. Comparative trials on a moderate scale are very advantageous: they remove many prejudices, and increase our profits. I always cross-plough after beans. The good effects of tillage are well illustrated in a conservatory where plants or shrubs are pot-bound or tub-bound, and one wishes to avoid repotting. The pot or tub is generally found to be filled with one solid mass or network of roots, so tightly packed that water cannot enter among them. In that case I soften the surface with water, divide the surface mass of roots by cutting them to pieces, fork the surface to the depth of 3 to 6 inches—in fact fallow as deeply as I can, getting gradually deeper and deeper. The sickly plant soon revives, and makes new shoots in spite of losing one-fourth or more of its roots, many of which have, no doubt, been long since useless. While following I continue watering from time to time with Peruvian guano and water (not too strong, about one-tenth of an ounce to the gallon). The result is a vigorously growing plant, where once it was pale, sickly, in fact almost dying. I have many such instances in my conservatory of the success of such fallowing, both with flowers and large camellias, &c. Before leaving tillage, let us recognise those two great tillage lights—Jethro Tull and the lamented Rev. Samuel Smith, of Lois Weedon. Let us congratulate ourselves on the application of mighty and untiring steam to the cultivation of the soil. It may, however, be well to remember that, unlike the horses it has superseded, it makes no manure. Chemical analysis has shown that the few inches of top or cultivated soil contain most of the money in our agricultural purse, each inch from the top containing less plant food than the one above it. This is because the surface soil has the power of arresting and fixing a large quantity of plant

food, especially ammonia (some of which it gets from the atmosphere), phosphate of lime and potash. The first inch (which, by-the-by, is 100 tons per acre of earth) gets the best chance of appropriation, and then come the next and lower ones, and as plants multiply their side fibres near the surface, we may comprehend why surface manuring is often found so beneficial—at least I have so found it. Now, as the first few inches of top soil would take much more plant food than we ever give it, we can readily imagine that the poor subsoil comes badly off; in fact, we see by its appearance that although so close to the top soil it is cold, dense, pale, and unaltered, and altogether different from the friable and manured surface soil. Can we wonder, then, that the plants look well while in their early growth—rejoice in the good things of the top soil? But when their main or tap root at the later stage of its growth descends into the cold empty subsoil, ought we to be surprised at the leaves looking bilious and queer?—"going to Halstead Fair" is the saying in Essex, because the fair takes place early in May; and they also say sarcastically that such plants forget to return. By following the first plough with another (without the breast) drawn by four strong horses, we break up the subsoil, and intermix it with the upper soil; by which means it participates, with the surface soil, in the manure applied. It does not answer to bury the top soil and overlay it with the under soil. With certain soils, like mine, it would injure the crops for years. The improper physical condition of soil impedes the working of plant roots and fibres. The dense, unmoved, unmanured, and un-aerated condition of the subsoil acts injuriously on those plants, such as clovers, turnips, and other deep-rooted plants, which depend upon the subsoil for their summer food. Hence the "going off" of our corn crops in May and June, just when they require the largest amount of food; hence the dying of clover in the spring. Its roots get starved when they reach the empty, unmanured, un-aired, and unwholesome subsoil. Clovers don't fail in the rich subsoils of gardens. Whenever I have thrown back the top soil and worked manure into the subsoil, I have been amply compensated. The field feels it for years. Both top and under soil should, if possible, be manured, for the roots of most of our crops descend several feet in drained soil. I know the case of a parsnip descending 13 feet 6 inches in a loose soil. It is because the subsoil has so little plant food in it that our deep-rooted crops can only be taken at long intervals. We cannot, to any great extent, manure the subsoil through the top soil; therefore they ought to be intermixed. Before I leave the question of tillage, permit me to say that I do not agree with those who condemn Essex heavy-land farmers for frequently disturbing their land by cultivation. I am convinced practically, and especially by the scientific reasons given by Liebig, that the frequent separation and intermixing of the granules of the soil during suitable weather is beneficial, chemically and physically—assuming, of course, that the land is drained, naturally or artificially. Keeping the crops free of weeds is, I know practically, one of the best and cheapest methods of enlarging our crops. The last saving a farmer should resort to is that of hand or horse-hoeing. The neglect in this matter is painfully obvious, and robs the country of millions annually. Don't tell me of sowing thick to smother the weeds. Every half-crown paid for hoeing does, I know, bring back 7s. 6d. The cultivation is worth the money, irrespective of weeds. I always horse-hoe my wheats, beans, and peas once or twice with Garrett's horse-hoe (at about 1s. per acre), and hand-hoe twice or even three times, at a cost of about 7s. 6d. to 10s. for the hand-hoeing. Women afterwards hand-pick any weeds that have escaped the hoe. We know by the leaves of our flowers when there is anything wrong below; so it is with our field crops, and as I came here by rail certain bilious-looking crops indicated an uncomfortable state of their roots, owing to want of drainage or food in the subsoil, or in consequence of weedy competition. If selling off the crops from the farm causes exhaustion, bringing them (or their elements) back again is the true and obvious way of restoring fertility. The difficulty of doing this by town sewage is by no means great, as I know by twenty years of practical experience, but I calculate that it will still be many years before landlords and tenants estimate its true value, and anxiously put forward their claims for those precious streams of the life-blood of the nation that would enrich their fields and increase

their gains. Our foreign importation of eatables and drinkables is over £70,000,000 sterling: much of this, as well as of our own produce, goes down the sewers. If all were applied to our soil it would greatly increase its fertility. Those who desire to know the effect of town sewage on every crop should read Mr. John C. Morton's recently published report of his experience at the Lodge Farm, Barking, with 300,000 tons of London sewage (published in a 2s. pamphlet, by Warne and Co., Bedford Row, London). If these facts do not open the eyes of landlords and tenants to the advantage of using and paying for town sewage, my opinion of the English character must be a wrong one. It is a disgrace to our intelligence that the use of sewage should be forced upon us mainly by sanitary rather than agricultural considerations. I must congratulate your county that the town of Leamington should have assembled a Sewage Congress, due, mainly, to the indefatigable and praiseworthy exertions of one individual. I am glad to find that Birmingham is at length taking steps to utilise its sewage. This is also being done by many lunatic asylums, unions, prisons, reformatories, and public charities. It does seem like a national absurdity to pay millions for birds' dung from Peru, and yet waste our own at home. But let us deal with the time and circumstances present. Let us admit that we waste our sewage, and that we are not yet sufficiently educated (agriculturally) to comprehend the physical and chemical conditions of our soil and its requirements. Let us confess that we don't believe enough in the agricultural chemist. I am now going to tell you of what I call a golden maxim for fertilizing our exhausted soils. Let your live stock consume, in proportion to each acre of your land, a large quantity of cattle food that was not produced on your own farm. Make, as it were, a farmyard or foldyard of your land, taking care that every particle of the manure, solid or liquid, shall go on to or into the soil. It is of little use to raise food on one side of the farm to be consumed on the other. That adds no mineral element to the soil: it is like "robbing Peter to pay Paul," or taking money out of the right-hand pocket to put in the left-hand one—the stock of money is not increased. All our most successful farmers use plenty of cake, that was not produced on their own farms, but is the produce of foreign countries. Import cattle food instead of man's food. I know some first-rate farmers who invariably consume £3 worth of cake per acre per annum over the whole farm. Such people have always plenty of corn to sell. These remarks apply equally to grass lands. Take foul and exhausted grass land, fold it closely with fattening sheep (not store animals), consuming plenty of cake, beans, malt combs, bran, roots, and hay, and its poverty will suddenly disappear. Half the kingdom is in grass land, and most of it is robbed and starved. That is a great arithmetical mistake—I mean subtraction instead of addition. I give this golden maxim as a practical farmer of 25 years; but if it is disbelieved or doubted, try an acre on each field. On this acre consume £8 worth of produce (cake preferred) that did not grow on your farm, and then keep an account of its produce for the next four years, and it will effect a most satisfactory change, both in your mind and pocket. Remember that, when by draining and high farming you have destroyed the sour worthless grasses, you must re-sow with good grasses and clovers adapted to the altered and improved condition of your soil. We are far too sparing as to sowing new grass seeds and clovers on our pastures from time to time. Having for 20 years used from £600 to £1,500 worth of purchased food, as well as each year some guano, &c., I am enabled to give you a practical opinion in favour of purchased food; and we have also in its favour Liebig, Way, Voelcker, and Lawes, so that we must give a decided verdict against artificial manures. Except on the score of want of capital, or for its portability, it is decidedly disadvantageous as compared with the sheep-fold or under-cover-made manure, all of the animals of course being highly fed on a variety of rich food. With poor lean-stock-made manure, guano and artificials show to greater advantage, and they are always useful as auxiliaries when we are short of the best cattle manure, which we rarely have in sufficient quantity. In certain exceptional cases, such as Cheshire—where the one element wanting was bone earth, bones—or superphosphate of lime, have been found of immense advantage. Artificial manures, and even guano, are deficient in some of the necessary plant food; therefore it has been found, on some light lands particularly, that the land gets tired of guano, and that it

has had an exhausting effect. Guano is certainly nearly 50 per cent. too dear in comparison with the best shed-manure, and its price regulates that of other artificials. The building up of a plant is like the building up of a house—we must first know what materials are required, and then take care that they are all provided in a suitable condition and proper proportion. The want of any one of them would render all the rest useless, although they were present in superabundance. Given, in the case of house-building, slates, bricks, lime, sand, boards, nails, and labour; still they would all be useless by the omission of water, or any one of the other materials. This is the great plant-lesson enforced and explained by that great philosopher Baron Liebig, whose works will, in 1868, be found in the library of every intelligent farmer. A ton of Peruvian guano costs £13; and taking this as a standard, Mr. Lawes has given in the following table the value of the manure produced from the consumption of a ton of various kinds of food. This may be said to settle the question against artificials; but then farmers must treat their manure as they do their guano—keep it free from rain-water. No farmer would think of scattering his guano over his farm-yard and allow the rains to wash much of it away; but it is equally wrong so to treat his home-made guano. He should always leave half-an-acre unmanured, or try artificial manures on a small space, so as to form a correct comparative opinion as to their value. This is too seldom done. We ought also more frequently to submit our cake and artificials to the agricultural chemist, whose large experience would, for a very moderate consideration, spare an immense amount of victimizing. This is one very obvious way in which science will benefit agriculture.

*Mr. Lawes' Table, showing the estimated value of the manure obtained from the consumption of one ton of different articles of food, each supposed to be of good quality of its kind:—*

Description of Food.	Present market price (about).	Estimated money value of manure from 1 ton of each kind of food.
1 Decorticated cotton-seed cake	£ s. d. 11 10 0	£ s. d. 6 10 0
2 Not decorticated	7 0 0	—
3 Rape-cake	7 0 0	4 18 0
4 Linseed-cake	11 0 0	4 12 0
5 Malt-dust	6 0 0	4 5 0
6 Bran	5 10 0	—
7 Lentils	—	3 17 0
8 Linseed	—	3 13 0
9 Tares	—	3 13 6
10 Beans	11 0 0	3 13 6
11 Peas	11 0 0	3 2 6
12 Locust beans	—	1 2 6
13 Oats	9 10 0	1 14 6
14 Wheat	17 10 0	1 13 0
15 Indian corn	9 0 0	1 11 6
16 Malt	—	1 11 6
17 Barley	11 0 0	1 9 6
18 Clover hay	4 10 0	2 5 0
19 Meadow hay	3 5 0	1 10 0
20 Oat straw	—	0 13 6
21 Wheat straw	2 0 0	0 12 6
22 Barley straw	1 10 0	0 10 6
23 Potatoes	6 0 0	0 7 0
24 Mangolds	1 0 0	0 5 0
25 Swedish turnips	1 0 0	0 4 3
26 Common turnips	0 12 0	0 4 0
27 Carrots	1 10 0	0 4 0
28 Fresh cut meadow grass	—	—
29 Ditto Italian rye-grass	0 17 0	—
One ton of meat (best quality) sells for 73d. per lb., or 5s. per stone of 8lbs.—say that it takes 8lbs. of corn or cake to make 1lb. of meat.		
1 ton of meat	...	£70 0 0
8 tons of rape-cake, at £6 10s.	£53 0 0	...
Cost of carting, breaking, feeding out, 6s. per ton	...	2 8 0
		54 8 0
		£15 12 0
Value of manure	...	39 4 0
		£53 16 0

So here we get £53 16s. worth of guano for nothing. Verdict for the plaintiff.

Take linseed cake, 8 tons, at £11	...	£88 0 0
Feeding out, &c....	...	2 8 0
		£90 8 0
1 ton of meat	...	70 0 0
		£20 8 0
Value of manure at £4 12s. per ton	...	£36 16 0
Loss on feeding	...	20 8 0
		£16 8 0
Value of manure	...	£20 0 0
Take 8 tons of beans, at £10 per ton	...	£80 0 0
Grinding and feeding out	...	4 0 0
		£84 0 0
1 ton of meat	...	70 0 0
		£14 0 0
Value of manure from 8 tons of beans, at £3 13s. 6d.	...	£29 8 0
Less	...	14 0 0
		£15 8 0
Value of manure	...	£15 8 0

All these calculations are founded on the estimate that it takes 8lbs. of cake or beans to make 1lb. nett of meat. Some people say 7lbs. will do it. Lawes says 5lbs. to 1lb. live weight. My live-stock account of last year (which you have no doubt seen) show that my animals consumed—

Of purchased cake and linseed	...	£228 0 0
Corn (principally beans and some oats)	...	236 0 0
Malt combs	...	17 0 0
Bran	...	42 0 0
Condimental food	...	35 0 0
		£558 0 0

Also the produce of 25½ acres of grass and green and root crops. After charging to the stock all the purchased food, the cost of producing the green and root crops, and all expenses of attendance (horse and manual labour), the balance or charge against the stock, or rather for the manure, was only £158 4s. 9d. In 1865 and 1866 the balance was still more favourable, because meat was dearer and feeding-stuffs cheaper than in 1867. The manure from the purchased food alone is worth (according to Mr. Lawes' table) about £240, besides the value of all the manure arising from the consumption of 25½ acres of home-grown green and root crops, and a large quantity of straw used as food and as bedding. Altogether, we can fairly take the manurial value of the whole as £340, against a loss of £158 4s. 9d. in feeding. I know also from experience that the farm manure greatly exceeds in effect the artificial manures. But you must not expect such favourable results as I get, unless you adopt my plan of economising food by comminution and variety, by giving it warm in winter, by under-cover feeding of cattle, and folding of sheep in summer; and, not least, keeping the manure under cover, and doing all the laborious portion by steam power, which I have now used for over 20 years. My cattle never got more than half-a-bushel (30lbs.) of roots daily, pulped and mixed with much straw chaff, 12lbs. of beammeal and cake, 1lb. each of bran and malt combs, ½lb. of crushed linseed, and 1lb. of condimental food. Roots and green food should only be used as salad with richer and drier food. They are expensive to grow, and the cost of them in handling and feeding out is great. A ton of cake worth £10 will only cost half as much to prepare and give to the stock as a ton of bulky and watery roots, worth 10s. to 12s. When given in the usual large quantities, they are rather physic than food, taxing unduly the urinary organs, and keeping the bowels too relaxed, for they contain 88 to 90 per cent. of water—but we are not here to-day to discuss the feeding question. Cheese-making and milk-selling are sad exhausters of the plant-food in the soil, unless the cows are largely supplied with supplementary food; and the system of raising and selling half-starved lean stock starves the land, the landlord, and the farmer, except on very rich soils. As a rule, I say, tell me how much fat meat you make per acre, and I will tell you how much corn you grow, for corn is dependent on fat-meat manure. Lime is a good servant, but a

bad master; lime (like earth burning) tends to render available the plant-food in the soil which was before unavailable, owing to its improper physical or chemical condition. Lime adds little manure to the soil; it only cooks or prepares what there is in the soil, and gets it ready for the plant. The continuous use of lime, or rather its excessive use, without ample manuring, has in too many instances impoverished the land, the tenant, and the landlord. It appears to me that one of the most important uses of chalk and lime is to neutralise or destroy the vegetable acids in the soil. In Essex, on our stiff non-calcareous clays, we all know that where a wood or fence has been removed from our heavy soil, no satisfactory crop can be got until the land is chalked, but I never heard any explanation of this except that the earth was sweetened. No doubt the land was sour, or rather the vegetable excretions—roots—were acid. Land that grows sorrel will no longer grow it after chalking. To test the action of chalk, I scraped some into powder, and placed in a wineglass as much as would one-fourth fill it. On pouring on to it some vinegar a violent ebullition took place, boiling over the mouth of the glass. No such effect could be again produced with the same chalk and vinegar. Both alkali and acid were neutralised. The farmers say it is of no use chalking a second time—at least for 14 years. This appears to explain why it is so. I have often been found fault with for not chalking or liming sufficiently, but I do not find the need of it, because the quantity of ammonia produced by my stock feeding under cover, effected, as shown by the crop, the same purpose as the chalk. Convinced of this, I asked the opinion of an eminent chemist, and he stated that ammonia was an alkali five times more powerful than chalk. Possibly it may be that the excess of ammonia in Peruvian guano acts favourably in cold sour soils, by neutralising or destroying acidity rather than as food for plants. I presume that the ammonia which results from the folding of sheep fed on rich nitrogenous food, such as cake, beans, &c., which enrich poor heavy land pastures, neutralise the acids produced from the immense network of dead grass fibres in the soil. Baron Liebig says that irrigating grass-lands produces the same effects as careful ploughing. It is easy then to understand the favourable effects of town sewage on grass lands, especially Italian rye-grass, for such sewage superabounds in ammonia, which is considerably in excess of proportion to the other ingredients of plant food contained in the sewage. I consider salt a very important ingredient. Although scarcely a manure in itself (except for saline plants, such as mangel wurzel) it confers many benefits by dissolving and distributing the phosphates that are already in the soil. It attracts and retains moisture in light soils, and on such soils is of very great value as a top-dressing, by preventing the ravages of wireworm. I always sow six imperial bushels per acre on my light land wheat and barley before the wireworm acts—that is, before the plant appears above ground. I know some persons who use as much as 5 cwt. per acre. I sow about  $1\frac{1}{2}$  cwt. per acre on heavy land (drained), mixed with guano for wheat and oats. The ashes of mangel wurzel contain much salt. An excess of salt renders the land barren for a time. Our stiff, plastic, non-calcareous clay, almost free from vegetable matter, becomes, when burned, real brickdust, and yet it is a most valuable fertilizer. Twenty years ago I burned an immense quantity, with great advantage. Science teaches us the why and the wherefore. Here it tells us that the hitherto unavailable elements of plant food locked up in our stiff clays become liberated by the action of fire, and rendered available for the feeding of our crops. But there is another and most important advantage. The physical condition of the soil is entirely changed by burning. The bird-lime, or putty-like soil, previously almost impervious to air or water, becomes loose and friable, permitting the free circulation of plant roots, and making the land work so much easier, and leave the plough breast readily. There is no safer investment on stiff clays than burning the nasty sticking, dense, unmanured subsoil; where coal is dear it must be dried by the atmosphere before burning, and is of course summer work. One old stump of a pollard will start and burn 140 cubic yards. The most notable and successful instance of earth-burning on a large scale is that of Mr. Randall, near Evesham. He has continued burning, winter and summer, for 20 years. Coal-dust is there very cheap, and one ton will burn twenty tons of earth. You have no doubt observed the immense mounds of earth burned for ballast or road basis for

railways, or where new streets are being made. Burned clay or brickdust is a capital manure for roots, owing to the alkalies in the soil being liberated by burning, especially so after being used as a bed for animals. It is a first-rate dry bed for sheep; a barrowful daily to about twenty sheep. It must be kept dry under cover or thatch ready for use. This is Mr. Randall's practice. When we have learned, as farmers, the value of straw for feeding purposes, we shall burn more earth and use more sparred floors. I have my eye on many thousand miles of great wide banks, mis-called fences, filled with worthless pollards and straggling bushes, untrimmed and uncared for. I would burn the lot, and then they would become a source of considerable fertility to the soil. Now they are robbers and impoverishers, and a breeding place for weeds and vermin; in fact, a regular nuisance. We can't afford to grow wood on cornfields now. Land is too dear for that, and coals too cheap. We must go for our wood to the non-rented forests of Canada.

The suggestions I have made necessarily lead us to consider perhaps one of the most useful lessons a farmer can learn—namely, "What is the most profitable amount of capital to invest per acre?" for on this depends much of his success. In a poor arable farm like mine, requiring much manure, I find £16 not enough, and I should prefer from £20 to £25. This, I know, is very much above the usual amount estimated in the general opinion, which is £10 per acre. Taking the whole country I do not believe it is so much as £5 per acre. In my balance-sheet you will have seen how this £16 was apportioned, the most important point being live stock £6 per acre. Is that too much on an arable farm? No. I wish it could be £10 per acre, as it ought to be, for the manure is in exact proportion to the live stock. In this respect no better confirmation of the soundness of the proposition, and no better example can be followed, than that of the agricultural labourer, with his one pig and his 20 rods of ground. That animal when fat is worth on an average £4 (say 8 score pounds of meat at 6d. per lb.), so that the capital invested in fat live stock is £32 per acre!!! and as the manure exactly follows the meat made, he makes probably twenty times as much manure as the average of farmers. This is a great lesson. Can we wonder that the cottage-garden is productive? I often hear labourers say, "If I don't fat a pig my garden becomes unproductive?" But then, how are we to get the capital? Well, credit is capital, and profitable capital too (although it belongs to somebody else), in industrious, careful, capable hands. Here the labourer, again, gives evidence. He buys his lean pig for £1. The miller trusts him with the three sacks of barley-meal that fattens the pig; and here, at once, is the £32 per acre capital in live stock. When he kills his pig he sells it, pays the miller, and has got the manure for his garden. Honest, industrious, capable farmers, having a lease, or an unchanging landlord, can go to the miller quite as well as the cottager does, and will find the rich cattle-dealer accommodating "for a consideration," to which he is fairly entitled. The banker obliges the cattle dealer, and uses a portion of his customers' deposits for that purpose. Have not many of our self-made men in the City of London and in your busy emporium (Birmingham) begun with no other capital than industry, honesty, and ability? Upon that sound foundation other people's capital has found a safe and profitable resting-place; so it is, or should be, in agriculture. Depend upon it, when agriculture is improved and so carried out as to become more profitable and less uncertain, capital will be readily found. But there must be "a will" and then there will be found "a way." I am bound in truth to say that it is the want of will and belief rather than the want of means that retards agricultural progress. The belief in money-making rather than the desire for cheap locomotion opened our purses, and emptied them too, to the extent of £500,000,000, in making railways. I have spun "a very tough yarn;" but if on taking it to pieces you can find a few useful threads, my object will have been accomplished, and I shall be much gratified. But as words without deeds do not carry their weight, let me invite a deputation from your Club to come and inspect my crops in July, just before harvest. You will then be able to judge practically of the results of my system. You will see seventy-three acres of wheat, which, judging from their present appearance, may compete with any crops grown on the richest land in the kingdom, although Tiptree Heath land is naturally notoriously

poor. You will probably pronounce them to be amply thick, although only sown with 1 bushel of seed per acre, and (although this is no part of our subject) you will conclude that an immense waste of seed occurs in this country which might be avoided by a better style of farming. Even the peck of wheat per acre may surprise you. You will also decide whether the money spent in procuring the absence of weeds is remunerative. You have had before you my balance-sheets (truthful copies of my accounts), and have therefore the means of judging by an inspection of the farm whether this year, be the price what it may, the crops are likely to prove remunerative. Believe me when I say that my sole object in making these remarks, and giving you this invitation is, as it always has been and ever will be, a sincere desire to increase and cheapen the food, and enlarge the sphere for employment of the British people, and concurrently to improve the farmers' and landlords' profit, and the general well-being and well-doing of our common country. This, in my opinion, is, in a

national point of view, the most important of our duties. The stomach cannot wait. The food question acts for good or for evil on all other interests, which are therefore more or less subservient to and dependent upon its quantity and price—revolutionary and rebellious principles find little room in well-filled stomachs; but hunger breeds discontent and fosters crime. The margin for agricultural improvement is, in this country, immense. I have often stated, and that statement has never been contradicted, that with skill and capital our home-food supply (meat and bread) might be more than doubled. Tiptree Farm is a proof of this, because its average quality is much below that of the kingdom, while its produce is much more than double that of the country at large. I am no participator in a fear of foreign competition. Let us, therefore, be dissatisfied with things as they are; let us apply our will (capital will speedily follow) to the better and cheaper feeding of Mr. John Bull.

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MONTHLY COUNCIL, Wednesday, June 3, 1868.—

Present: The Duke of Richmond, K.G., president, in the chair; Lord Bridport, Lord Kesteven, Lord Tredegar, Sir J. V. B. Johnstone, Bart., M.P.; Sir A. K. Macdonald, Bart.; Sir W. Miles, Bart.; Sir H. Vane, Bart.; Sir Watkin W. Wynn, Bart., M.P.; Mr. Amos, Mr. Baldwin, Mr. Barnett, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Davies, Mr. Dent, M.P.; Mr. Druce, Mr. Edmunds, Mr. Brandreth Gibbs, Mr. Hassall, Mr. Holland, M.P.; Mr. Hornsby, Mr. Hoskyns, Colonel Kingscote, M.P.; Mr. Milward, Mr. Pain, Mr. Randall, Mr. Ransome, Mr. Sanday, Mr. Shuttleworth, Mr. N. C. Stone, Mr. Torr, Mr. Thompson, Mr. Webb, Mr. Wells, Major Wilson, Mr. Jacob Wilson, and Dr. Voelcker.

The following new members were elected:—

Anderson, Charles G., Countesthorpe, Leicester  
Arablin, W. St. Julien, Englefield Green, Surrey  
Badeock, Rev. Thomas, Fleckney, Market Harborough  
Berridge, Thomas, Sutton, Lutterworth  
Berry, William, 95, High-street, Leicester  
Bluecke, Rev. William Strong, Willoughby, Lutterworth  
Bowden, W., jun., Prospect House, Cirencester  
Brierley, Harry, Church Lawford, Rugby  
Brook, Charles, Enderby Hall, Leicester  
Burley, Wm. Robinson, Leicester  
Burney, George, Millwall, London, E.  
Catlin, Richard Edgar, Leicester  
Chamberlain, Henry B., Ivy House, Desford, Leicester  
Chapman, William, Apethorpe, Peterborough  
Clarke, John Sanders, Seating Hall, Lutterworth  
Cooper, Alfred Allen, Leicester  
Crawford, Miss, Hill House, Farnsfield, Southwell  
Dain, M. J., Leicester  
Davies, Benjamin, Huyton, Chorley  
Duff, Alexander M., 37, Gallowtree Gate, Leicester  
Eckersley, James, Burnt House, Chorley, Lancashire  
Ellis, James, Glenfield, Leicester  
Emberlin, Horatio Edwin, Oadby, Leicester  
Fletcher, George, The Friars, Leicester  
Fletcher, Wm. Ainton, Shipton Oliffe, Cheltenham  
Foster, John, Copson Lodge, Hincley  
Fowke, Frederick Thomas, Lowesby Hall, Leicester  
Fowler, Robert, Leeds  
Foxton, George, Prebend Terrace, Leicester  
Furness, Rev. John Monteith, Oakfield, Rugby  
Gee, John, Welford, Rugby  
German, William, Measham Lodge, Atherstone  
Gerrard, John, Adlington, Chorley  
Godfrey, William, Borough Fields, Walton, Burton-on-Trent  
Goodacre, R. J., 22, Lower Hastings-street, Leicester  
Green, William, Leicester  
Grinston, Captain R. V. Sylvester, Leicester

Hack, Matthew, Leicester  
Harcourt, Edward Wm., Stanton Harcourt, Witney  
Hardwick, Richard, Bowdon, Altrincham  
Harrison, Thomas, 3, The Crescent, Leicester  
Hartopp, Sir John, Bart., Four Oaks Hall, Sutton Coldfield  
Hassall, Thomas, Rearsby Rectory, Leicester  
Hawkes, Thomas, Tiverton  
Higginson, John, Humberstone Road, Leicester  
Hill, Abraham, St. George's, Leicester  
Hodges, Frank, Mayfield, Leicester  
Hodges, George Henry, Stonygate, Leicester  
Hodges, John Edward, Stonygate, Leicester  
Hodges, Thomas William, Mayfield, Leicester  
Hollingworth, John, Market-street, Leicester  
Hood, the Hon. A. W. A. Nelson, Cumberland Lodge, Windsor  
Hoskyns, Rev. Henry James, Blaby Rectory, Leicester  
Howard, E. M., Great Withingham, Norwich  
Howland, A. R., Ludesdon House, Thame  
Hubbersty, Wm. Philip, Wirksworth  
Innocent, Arthur, Kibworth, Beauchamp, Leicester  
Johnson, Wm. Henry, Old Hall, Braunstone, Leicester  
Jones, John, Maes-y-pandy, Machynlleth, Merionethshire  
Mayman, B., 56, Drury Building, Water-street, Liverpool  
Miles, William, Leicester  
Odames, Samuel, Leicester  
Overton, Robert, jun., Leicester  
Ouston, H. A., Bushloe House, Great Wigton, Leicester  
Parrish, Richard, The Uplands, Bridgnorth  
Parrott, John, jun., Norfolk Farm, Staines  
Pearson, Wm., North Kilworth, Rugby  
Pochin, R. G., Braunstone House, Leicester  
Potterton, Wm. H., Boughton Grange, Northampton  
Preston, James, Leicester  
Pugh, Wm. C., Stratford Villa, Woburn Road, Croydon  
Ratcliff, Thomas, Norton-juxta-Twyeross, Sheepy, Atherstone  
Sarson, John, Leicester  
Saunders, Charles R., Nunwick Hall, Penrith  
Shipman, Robert M., Bredbury, Stockport  
Stone, Joseph C., Rowley Fields, Leicester  
Stone, Samuel, Glenfield House, Leicester  
Tate, Wm. James, St. Margaret's, Dunham Massey, Altrincham  
Thorpe, William, Shenton, Nuneaton  
Tyrwhitt, Sir Hy., Bart., Ashwell Thorpe Hall, Wymondham  
Whitaker, B. I., Healey Hall, Tickhill, Rotherham  
Willett, Geo. W., West House, Portland Place, Brighton  
Wood, Charles Henton, Thurlaston, Hincley  
Wood, Rev. W. Paul, Saddington Rectory, Market Harboro'  
Worswick, R. W., Normanton Hall, Hincley

FINANCES.—Major-General Lord Bridport presented the report of the committee, from which it appeared that the Secretary's receipts during the past month, amounting to £1,135 1s. 6d., had been examined by the committee, and by Messrs. Quilter, Ball, and Co., the Society's

accountants, and were found correct. The balance in the hands of the bankers on May 31 was £3,508 2s. 4d. The committee had heard with regret of the death of Inspector Bradstock, of the Metropolitan Police, who for many years rendered good service to the Society at their annual Shows, and desire to record their expression of sorrow, and suggest that the Secretary be empowered by the Council to convey their sincere sympathy to his widow. This report was adopted.

**JOURNAL.**—Mr. Thompson, chairman, reported that in consequence of the lamented death of their late Editor, it has been necessary to make temporary provision for carrying on the *Journal* work, and, subject to the approval of the Council, the committee have made arrangements with Mr. Goodwin to bring out the next Number. The committee recommended that a list of members be printed in the next Number. The arrangements connected with filling up the vacant post of Editor having been the subject of much discussion at two successive meetings of the committee, at which considerable variety of opinion was expressed, it was finally resolved that the question should be referred to the Council for their consideration and decision. This report was adopted. Mr. Randell having moved that in future the Secretary of the Royal Agricultural Society of England be also Editor of the *Journal*, was seconded by Lord Bridport, and supported by Mr. Milward, Colonel Kingscote, M.P., Mr. Bowly, Mr. Holland, M.P., Mr. Jacob Wilson, and Mr. Torr; and opposed by Colonel Challenger, Mr. Thompson, and Mr. Dent, M.P. The wording of the motion having been altered to "That after the 1st January, 1869, the offices of Editor and Secretary shall be held by the same gentleman," it was supported by Lord Bridport, and, after a long discussion, carried by 23 Ayes to 5 Noes.

On the motion of Sir W. Miles, a committee, consisting of the President, Earl Cathcart, Lord Bridport, Mr. Dent, M.P., Mr. Edmunds, Mr. Brandreth Gibbs, Mr. Wren Hoskyns, Mr. Randell, Mr. Thompson, and Mr. Wells was appointed, to consider how the decision is to be carried out.

**CHEMICAL.**—Sir John Johnstone stated that Dr. Voelcker reported that he has in preparation a paper on the special causes of the beneficial effect of Clover as a preparatory crop for Wheat, embodying some of the laboratory results of an investigation into the chemistry of the Clover plant. There is also standing over from the last *Journal* a paper, already in type, on the composition and nutritive value of *Trifolium striatum*, a new kind of Clover, especially adapted for poor sandy soils. The committee beg to call the attention of farmers to the fact that the number of adulterated guanos this season in the market is unusually large; and in some cases, where it has been sold by auction, the sample proved to be not worth one-fourth of the price paid for it. The committee cannot help expressing their regret that the trade in spurious manures should receive encouragement by the system of purchasing manures (an article so liable to adulteration) by auction sales.

**LEICESTER MEETING.**—Mr. Thompson, chairman, reported the recommendation of the committee, that Mr. Elphick be engaged as Assistant-Steward, on the usual terms; that shedding and hurdles, as per entries, be ordered from the contractor; that 10,000 stock catalogues and 5,000 implement catalogues be printed; that the charity and union workhouse schools shall be admitted free to the show-yard on the last day of the show, subject to such regulations as the local committee think desirable.

**Manchester Meeting, 1869.**—That it is desirable that some member of Council should superintend and direct the preparation of the land for the trial of implements, and make arrangements for the supply of forage to the show-yard. The committee recommend that Mr. Davies

be requested to undertake this duty, and authorized to make all the necessary arrangements, and a statement of the probable quantities required to be sent to him by the Secretary. This report was adopted.

**IMPLEMENTS.**—Mr. Thompson reported the following list of prizes, to be offered for competition in 1869:

*Machines and Implements for the Harvesting of Crops.*

Sect. I. For the class of mowing machines—for two-horse machines, £50; for one-horse machines, £30.

Sect. II. For the class of hay-making machines, £30.

Sect. III. For the class of hay collectors, £15.

Sect. IV. Reaping machines: 1. For the class of reaping machines with self-delivery, in sheaf, clear of the horse track, £60; 2. For the class of reaping machines with self-delivery, in swathe, clear of the horse track, £60; 3. For the class of reaping machines without self-delivery, £30; 4. For combined reaping and grass-mowing machines, £30; 5. One-horse reapers, £30.

Sect. V. For the class of horse-rakes, £30.

Sect. VI. Waggon: The class of—1. Pair-horse waggons, £30; 2. Other waggons, £20.

Sect. VII. Carts: The class of—1. Single-horse carts, £20; 2. Two-horse carts, £20; 3. Harvest carts, £15; 4. Market carts on springs, £10; 5. Liquid manure carts, £10.

Miscellaneous awards to agricultural articles and essential improvements therein (10 Silver Medals).

This report was adopted.

**EDUCATION.**—Mr. Holland, M.P., stated that the committee recommended that the thanks of the Council be given to each of the Examiners for the service rendered, and that each of the nine gentlemen who are not members of Council be presented with the sum of £5. Of the £200 allotted to education, £119 14s. 6d. has been expended as follows, viz., 9 Examiners, at £5 each, £45; awarded in prizes, £60; expended in printing and advertisements, £14 14s. 6d.: £119 14s. 6d. This report was adopted.

**SHOW-YARD CONTRACT.**—Mr. Randell, chairman, presented the following report from the surveyor:—

"The Show-yard works at Leicester are progressing very satisfactorily, and are fast approaching completion. The main entrances, and the whole of the Society's portable buildings are ready for use. The outer fences and gates are also completed; two-thirds of the cattle sheds, horse-boxes, and stables are also erected. Seed and model sheds complete, and the whole of the implement sheds, including those erected by the Society for exhibitors in machinery in motion yard, are in a forward state; 7,000 feet of the former, and the whole of the latter, are already completed. The fodder and nurse-cow sheds are also completed. The Local Committee are making great efforts to make everything complete, the levelling already done in the show-yard is far more than asked for, and the roads and approaches, both from railway-siding to receiving yard, and to the entrances for carriages and foot people, when completed (and is already in a forward state), will be everything that can be desired. The railway siding is in a forward state, but the dock and platform accommodation is insufficient; this I have pointed out to the local engineer, and orders have been sent him from Derby to increase it."

It is recommended that the Royal Horticultural Society be asked to join in the expense of erecting a shed over turnstiles in the fence between the Show-yard and their grounds; one of the Society's turnstiles, and one belonging to the Horticultural Society, being placed in such fence. The surveyor having certified that the contractor is now entitled to the sum of £2,000, the committee recommend the payment of that sum. The committee recommend that the surveyor go to Manchester, and prepare a preliminary plan of the Show-yard, previous to the next Council meeting. This report was adopted.

Mr. TORR having called attention to the subject of refreshments in the Show-yard, it was referred to the Manchester Committee.

**JUDGES.**—A committee, consisting of Lord Bridport, Sir Archibald Macdonald, Bart., Colonel Kingscote, M.P.,

Mr. Dent, M.P., Mr. Amos, Mr. Bowly, Mr. Davies, Mr. Druce, Mr. Brandreth Gibbs, Mr. Randell, Mr. Milward, Mr. Sanday, Mr. Torr, Mr. Webb, Mr. Wells, Major Wilson, and Mr. Jacob Wilson, were appointed to recommend judges of stock, implements, wool, butter, and cheese; whose report would be presented at a Special Council on the 16th inst.

A suggestion to the Council made at the general meeting by Mr. Lewis Fytche—"Mr. Miles' paper on Horse-Shoeing contained in Vol. XVIII. of the Journal being out of print, that 1,000 copies of the same be printed for the use of Members"—was referred to the Journal Committee; and that by Sir George Jenkinson, Bart.—"That the Council will, at any future show after

the present year, offer a few prizes for village farriers or blacksmiths to compete for, in making, fitting, and nailing-on shoes on horses, both for hunters and for those used for agricultural purposes; certain conditions to be specified, and inspection to be made of the work done by a properly qualified veterinary surgeon, by whom the principles to be followed and the faults to be avoided shall be pointed out to the various competitors, and the prizes for this class shall be awarded by a committee of, say, three gentlemen, specially appointed for that purpose, assisted, perhaps, by the veterinary surgeon above mentioned: this has been tried in Gloucestershire, and with very great benefit"—was referred to the Manchester committee.

## ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.

The eighth annual dinner of this institution took place on Wednesday evening, June 3, at the Freemasons' Tavern, under the presidency of Viscount Enfield, M.P. About 100 gentlemen sat down.

It appears that there are on the books of the institution 20 male pensioners, at £26 per annum; eight married pensioners, at £40 per annum; 32 widow pensioners, at £20 per annum; four unmarried orphan pensioners—the orphans, however, being women of the respective ages of 60, 67, 63, and 80; and four widow pensioners, at £10 per annum. In addition to these the society has in the course of its brief career aided 23 male pensioners, seven widow pensioners, and three unmarried orphan pensioners, all deceased. The operations of the society involve an expenditure of about £5,000 a year, and, although it has £20,000 of funded property, it still requires, to meet present demands, an income of about £5,000 from subscriptions and donations. This sum is obtained from hundreds of supporters all over the country, who are however unequally distributed, as some agricultural districts do not contribute so liberally as others, owing possibly to the fact that the claims of the institution have not been equally advocated in all.

After proposing in suitable terms "The Health of Her Majesty,"

THE CHAIRMAN gave "The Prince and Princess of Wales, and the other Members of the Royal Family." In doing so he spoke of the interest which the present race of English sovereigns has always manifested in regard to agriculture; observing that George III. received the appellation of "The Farmers' Friend," while the present heir to the throne had combined with a love of country pursuits a great fondness for field sports. The noble lord also congratulated the assembly that the Princess of Wales—the good and sweet princess who had endeared herself to the whole nation—had again delighted the public by appearing among them after her protracted illness.

The next toast was "The Army, Navy, Militia, and Volunteers," in proposing which the CHAIRMAN adverted to the Abyssinian Expedition, and the success which had crowned it, as affording fresh evidence that the army of Great Britain was equal to any emergency that might arise.

Lieut.-Col. Sir CHARLES RUSSELL, M.P., in responding for the army, also alluded to the Abyssinian Expedition, and remarked that one great advantage connected with it was the salutary impression which it had made on the Eastern mind. He also observed that that was the last time he should appear on such an occasion as a representative of the army, as he had already placed his commission in the hands of her Majesty.

The Rev. Mr. McCALL, as a Volunteer chaplain, returned thanks for the Volunteers, and congratulated the company on the improved position of the nation relatively to other nations in consequence of the organization and efficient condition of that branch of the military service.

THE CHAIRMAN then rose and said, in bringing under their consideration the toast of the evening, which was "Prosperity to the Royal Agricultural Benevolent Institution," it was his wish to detain them as short a time as possible. Still there were circumstances connected with their gathering there on

that occasion which he should be sorry to omit noticing, because he was anxious that, through the medium of the public press, the advantages which the institution had conferred, was conferring, and was likely to confer, upon the agricultural interest throughout England, should be well known (Hear, hear). With their permission then he would glance for a few minutes at its past history; he would next consider its present position; and then he would trust to their generosity, to their sympathy, and to their recommendations of its claims among their friends and neighbours, for its future success (cheers). He believed he was correct in saying that the institution owed its origin, some eight years ago, principally if not entirely to the exertions of a gentleman who was now seated on his left hand, his friend Mr. Mechi (Hear, hear). Feeling deeply impressed with the fact that in this country, a country so peculiarly devoted to agricultural pursuits, every guild, and every profession, excepting the agricultural interest, had some benevolent or charitable institution connected with it, Mr. Mechi directed his exertions to provide a remedy for this state of things; success attended his exertions, and the institution was now in the eighth year of its existence (Hear). He need scarcely remind them that its principal object was to provide pensions for *bond fide* farmers, their widows, and unmarried orphan daughters, and to educate their orphan children; and he thought he could not do better than present in as concise a form as possible its annual budget for their consideration. There were at that moment then 68 pensioners of the Society, consisting of 20 males, who received £26 per annum each, 8 married couples receiving £40 per annum each, 32 widows with £20 a year each, and 4 unmarried orphan daughters and 4 widows who received £10 a year each. Having looked into the balance-sheet he found that on the 18th of February last there was an excess of income over expenditure of £760, whilst the funded property of the institution consisted of £12,000 in Consols and £8,000 in the Three per Cents. Reduced, in the whole £20,000, which was a very good nest egg (loud cheers). An analysis of the subscriptions from the different counties, however, was somewhat a source of dissatisfaction; and his friend Mr. Mechi having attended to this subject in a letter which he had written to the public prints, he (Lord Enfield) might perhaps be allowed to refer to it here. It should be remembered that the institution made no distinction whatever between counties, and that all who received the proper number of votes were elected and got their pensions irrespective of the counties they might come from. But he found that there were some counties which did not respond to the appeals of the institution so generously as they ought in proportion to their acreage. There was, for example, the great county of Devon, with 1,654,400 acres; it contained only 45 subscribers. Yorkshire, again, with 3,735,000 acres, had only 48 subscribers; whilst Hampshire, with its 970,470 acres, had 641 (cheers). Essex, with 921,120 acres, had 645 subscribers, and the county with which he was more immediately connected, Middlesex, with 186,480 acres, he was glad to see mustered 468 subscribers (cheers). Lancashire, with its 1,130,240 acres, on the other hand, furnished only 12 subscribers; Lincolnshire, with an acreage of

1,671,040, only 64 subscribers; whilst Northumberland and Cumberland together had only 8 subscribers, though their united acreage amounted to 2,172,160. He spoke in no cavilling spirit; but he really thought that as all the counties enjoyed the same advantages, without distinction, they ought to send a number of subscribers that was in fair proportion to their acreage (Hear, hear.) Now, with regard to farming generally, he was quite sure that in that society, where there were some of the most distinguished agriculturists from all parts of England, it would be bad taste in him to say anything on the practical part of the subject. If he did so he knew he should only betray his own ignorance; he should, therefore, only tread upon what he believed to be safe ground (laughter.) He looked upon farming in two points of view; first, as an amusement, and, second, as a profession or occupation. As an amusement, it was the most healthy, the most moral, and the most English that any gentleman could indulge in (Hear, hear.) But as a profession or occupation, he was quite sure there was none that was embarked in more seriously, and oft-times with greater misgivings (Hear, hear.) In every profession they knew well that, without the blessing of Providence, it was lost labour to rise early, late take rest, and eat the bread of carefulness; but when they considered that the agricultural interest was more than any other dependent upon that blessing for success, that at the proper time the early and the late showers, the dry winds, and the vivifying and warm sunshine were required, he was sure that the farming class must feel above all that they were dependent upon Providence, and that this institution, more than any other, gave them the means of laying by store for bad times (cheers.) On looking through the list of those who were pensioners of the Society, he found that nearly all the causes by which those persons had become pensioners on its bounty were loss of crops, bad times, heavy rains, mildew, blight, cattle plague, and other events over which human beings had no control whatever, and which were solely at the disposition of Providence (Hear, hear.) One source of gratification to him in the Society's report was to find that so little was spent in bricks and mortar. On reading the account of the last annual dinner he observed that mention was made of the fact that with the exception of occupying two rooms at Charing Cross, the Society have nothing to do with bricks and mortar (Hear, hear.) Consequently they were not called upon to add a wing to a building one year, and another wing another year; and it must be a source of comfort to those who were dependent upon their bounty to know that they had not to leave their native homes, their healthy villages, or their breezy downs, to take up their abode and be stewed in buildings in the heart of a great and stifling city, where they might be said to a certain extent to be deprived of their liberty (cheers.) The good which the institution did was done at home. The pensioners received their pensions at home, and had not to leave the places with which they had been identified all their lifetime from earliest childhood (Hear, hear.) He remembered having been personally canvassed some years ago to give his support to the Society, by their excellent secretary Mr. Shaw, who then made a suggestion to him which he would recommend to his brother members. It was that, whenever they attended any agricultural gathering in their respective counties, they should always seek an opportunity of saying a few good words in behalf of the institution (Hear, hear.) The good which it did only required to be known, and he was sure there would be hearty help and cordial response from the length and breadth of the land in aid of its object (Hear, hear.) It might be asked in whose behalf he made this application; his answer was, on behalf of the farmers of England. And now, he was going to do what was, perhaps, a rash and a dangerous thing. He was going to draw their picture, but it was a mere outline sketch, and he must leave his hearers to fill in the details. First, the farmer was a typical Englishman, attached to his country, and a supporter from his birth of the Queen and Church (loud cheers.) In the next place, he was a strong politician, but at the same time he was a generous opponent, and respected consistency in himself and others (cheers.) He was also a hospitable man. He was a true sportsman. He never grudged his landlord a good day's shooting, but he deprecated from the bottom of his heart, as he (Lord Enfield) did, the pernicious and mischievous system of over-preserving, which was the ruin of many a farm (Hear, hear.) Lastly, he was a warm admirer of the three noblest works of creation—a handsome woman, a clever horse, and a well-shaped hound

(loud cheers and laughter). This, he admitted, was only a fancy sketch rather rudely drawn, but it was one which a little observation had told him was not an untrue one; and in conclusion, re-echoing the old sentiment of "speed the plough," he would offer three wishes. One was, that the good understanding which he hoped now more than ever existed between landlord and tenant—between those who tilled the soil and those who served under them—might long continue to exist; that the farmers of England would, as they had hitherto done, take every opportunity of doing good to themselves and their neighbours, by making use of all those advantages which modern experience in machinery and chemistry would suggest to them; and that by the blessing of Providence the expectations which at the present moment we might fairly entertain of a bountiful and full crop might be more than realised this year (loud cheers.) He thanked them respectfully for the attention with which they had listened to him in proposing the toast, and with all sincerity and earnestness he called upon them to join him in drinking continued prosperity to the Royal Agricultural Benevolent Institution of England (The toast was received with three times three, and loud cheering.)

Lieutenant-Colonel Sir C. RUSSELL, M.P., proposed "The Chairman;" and after the toast had been drunk with cordiality the noble lord briefly returned thanks.

Mr. MEECH had been entrusted with the duty of proposing as the next toast, "Prosperity to the Three Great Agricultural Societies of the United Kingdom." In doing so, however, he need not enlarge upon the great benefits which these institutions had conferred upon British agriculture; but he was happy to say that in connection with the toast he was to add the name of one of the best farmers in England, under one of the best landlords in England: he alluded to his friend Mr. John Hudson, of Castleacre (cheers.) If the whole country were farmed, taking arable and pasture, in the same way as that portion of the county of Norfolk which was the property of the late Mr. Coke, and the present Lord Leicester, and which was held by Mr. Hudson, we should not hear so much as we now did about the necessity of foreign importation (Hear, hear.) They had been drinking his (Mr. Meech's) child's health that evening, and he could not pass over the subject without saying a few words in regard to the bantling. At present it was a mere infant; but if he could come again a hundred years hence, which he should certainly not do, he believed he should be astonished at the proportions it would have attained. He had good grounds for saying so; for we had 60 million acres of land, beside 17 million of mountain and waste: and if every farmer only subscribed a penny an acre they would have an income of £250,000 a-year, or if he subscribed but a farthing an acre they would have an income of more than £60,000 a-year. So that he was encouraged to hope that his bantling would by-and-by grow into a good-sized man. (Cheers.)

Mr. J. HUDSON, of Castleacre, in responding, said, the people of this country could not afford to have half crops; they wanted cheap food—cheap bread and cheap meat—and it was only through landowners giving great encouragement to tenants, and the exertions of the tenants themselves, that that national want could be met. Happily agriculturists were marching on in the right direction, and the rate of march was accelerated by the accession of steam. A few years ago no one scarcely believed in the applicability of steam to the cultivation of the soil; but he had lived to see the day when steam was so applied, and he had no hesitation in declaring that he had himself used it with advantage. Cultivation had of late made great strides, and farmers must put their shoulders to the wheel, and they will double the produce of the land.

The Rev. G. C. BERKELEY proposed "The Executive Council" which toast was acknowledged by Mr. John Collins. Among the remaining toasts were "The Secretary" (Mr. Charles Shaw), "The Stewards," and finally "The Ladies."

The subscriptions announced in the course of the evening included 25 guineas from her Majesty, and 10 guineas from the Prince of Wales, the aggregate being about £4,000.

The musical arrangements were under the direction of Mr. G. Perren, who was ably assisted by Miss Mabel Brent and Miss Palmer, Mr. T. Lawler, and Mr. L. Hatton, the last-named gentleman presiding at the piano-forte.

Previous to the dinner, a special meeting of the Council of the Royal Agricultural Benevolent Institution was held at

the Freemason's Tavern. Present, Messrs. C. S. Cantrell (chairman), J. Collins, H. Corbet, A. Garrett, J. Howard, J. Hudson, A. H. Johnson, J. J. Meehi, J. Naish, T. Scott, G. Shackell, and W. Vivian.

The business of the meeting was confined to the consideration of the necessary steps to be taken in filling up the secretaryship, about to become vacant from the resignation of Mr. Charles Shaw.

It was resolved that Mr. Shaw's tenure of office close at Michaelmas.

It was resolved on a division, by 6 to 5, that an advertise-

ment inviting applications for the appointment be *not* inserted in *The Times* and the agricultural journals.

It was resolved that the appointment be filled up at a meeting of the Council, to be called for the first Monday in July.

Mr. Charles Shaw, jun., a candidate for the office, had an interview with the Council.

It was proposed also to call on Mr. J. N. Lee, who, however, did not appear to be in attendance.

The Council sat for nearly two hours, and the discussion was at times very animated.

## THE BATH AND WEST OF ENGLAND SOCIETY.

### MEETING AT FALMOUTH.

Cornwall—of which Falmouth is one of the principal towns—is in popular estimation one of the last counties of England with which agricultural associations are or could be connected. The very aspect of the country indeed is supposed to give rise to associations anything but Arcadian. Bare and rugged hills; bleak moors; a coast singularly wild, abrupt, and grand in its outline, fringed here and there with wood, the appearance of which indicates the hard struggle they have to maintain against ungenial air and biting frosts—all tell of a country the characteristics of which, in an agricultural aspect, are the very antipodes of the rich rolling lands, the fine soil, and wooded glades of more favoured counties of Merrie England. The very population, too, in their garb and manner tell of a mode or modes of life very different from that met with in purely agricultural districts. Nor is the cause of this supposed difference difficult to be met with. Everywhere around are the marks of mining operations, which afford subsistence to the main part of the population. Such may be said to be the popular or Guide Book—not published, it is needless to say, in the county—view of this, in many respects, remarkable part of her Majesty's dominions. Much, if not indeed the whole of it, does indeed apply to one part of Cornwall, but that is comparatively a limited part. Certainly it does not apply to the part which is passed through from Plymouth to Falmouth, nor in the country immediately around the latter town. Of the whole ride extending between those two towns it may indeed be said that in point of rural and picturesque beauty some of the districts of England celebrated in this way will have a difficulty to compete with it; in some respects it cannot be excelled. The lateral valleys, for example, which open up on both sides of the railway, are very numerous and very beautiful, spanned by viaducts of great height and length, and rich in wooded valleys and bosky dells. Little arable land comparatively is seen from the railway, the land being chiefly under pasture, and, as may be gathered from what has been above stated, there is much wood, which gives a rich and charming appearance to the country. And truly ample time is given to the traveller to observe the scenery through which he passes; for, although now and then the train—at least the one we travelled with was possessed of this peculiarity—passed pretty rapidly on, it made up for the rapidity of its flight at such times by the staid slowness at others, and by the patient placidity with which it waited at stations, which, fortunately for the impatient traveller, were generally at points of considerable beauty. We were supposed in the official mind to be travelling "express;" but the thought was forced upon the mind of him who was accustomed to more pushing modes of progress, if that was the express, what could possibly be the slow

train? that forced one back to the good old coaching days, when "slow but sure" was the motto.

From what we have stated it will have been surmised, what is indeed the fact, that the agriculture of Cornwall is peculiar. There is, or at least was, in the old system, little pasture land, using this term in its highest significance; yet, under the influence of good husbandry, the soil bears a sward of a peculiarly firm texture. Under the old system, cereals were taken off the land in succession, and the exhausting effects of such a system may be easily conceived. But with the introduction of the alternate and green-cropping system of cultivation, a great improvement has taken place.

The situation of the show-yard is very beautiful, in a field sloping gently down, and almost to the edge of the bay. The upper part is high enough to give a splendid view on either side. And the weather of this, the first day, was all that could be desired to give the utmost degree of artistic effect to the whole scene. A fine clear sky, with rolling clouds in it, sufficient to give that play of light and shade on hill-top and valley-side so dear to the lover of Nature, and so prolific of artistic effect. The sea, like a lake in its calm beauty, lay shimmering in the sun, speckled with whitened sail of stately ship or tiny boat.

The entries of stock were small, compared with the meeting of the Society at Truro, in 1861. The show, however, was on the whole a good one; and although numerically weak, the cattle, sheep, and pigs will contrast favourably with any of the Society's previous exhibitions. There were 79 entries of cattle, as compared with 134 in 1861; sheep 141, as against 234 at Truro; horses 36, compared with 89; and pigs 86, against 42. The cattle consisted of Devons 49, Shorthorns 24, Herefords 6; of sheep—Leicesters 48, Cotswolds 16, South Downs 13, other Downs 40, Somerset and Dorset horned sheep 23. Horses for agricultural purposes numbered 8, hunters 17, hacks 4, and ponies 7. There was, as usual, a varied display of articles of taste and utility in the building devoted to art manufactures.

The Devons were remarkably good, comprising 24 bulls and 25 females. In class 1st, bulls not exceeding 4 years old, there were eight entries; the competition being between Mr. Turner's Albert Victor, Mr. Mason's, a local exhibitor, bred by Mr. Davy, of Flitton; Mr. Buller's, Mr. Walter Farthing's, and Mr. Clarke's, bred by Mr. Farthing. The judges had no difficulty in giving Mr. Turner the first prize, and they awarded the second to Mr. Mason, highly-commended Mr. Buller's, and commended Messrs. Farthing's and Clarke's. In class 2nd—bulls not exceeding 2 years old—there were sixteen entries. The competition was very spirited, and altogether this was an unusually good class. The judges selected

six, viz. Mr. Walter Farthing's Duke of Gotherlney, Mr. Farthing's Master Arthur, Mrs. Tremaine's Lord Aylmer, Mr. Beckle's Perfection, Mr. Buller's, and Mr. Wm. Smith's; and, after a long consultation, they awarded the first prize to Master Arthur, a very thick good yearling, well got up; but the public thought the second-prize animal, Mr. Buller's, was more matured, and had better points, and that the first-prize one would not train so well. We believe the judges were not unanimous in this decision. Mrs. Tremaine's and Mr. W. Smith's entries were highly-commended, and Mr. Bickle's and Mr. Farthing's commended. Class 8 contained nine entries, and among them were some good cows. The first prize was deservedly awarded to Mr. John A. Smith, of Bradford Peveril, who also had another highly-commended; the second prize going to Mr. Walter Farthing, Mr. Tremaine's Rose 2nd being highly-commended. Class 4—heifers not exceeding 3 years old—brought together a very beautiful lot, and which gave the judges some trouble. The first prize was eventually awarded to Mr. Buller, of Downs, for a remarkably good heifer, which, we hear, is intended for the Royal at Leicester; Mr. Turner winning the second with a very beautiful heifer, and Mr. Walter Farthing and Mr. Hambro receiving high-commendations. Class 5—heifers not exceeding 2 years—contained six entries. This was not so good a class as the previous one. Mr. Turner's Duchess 6th won the first prize, Mr. Buller's the second, and Mr. Walter Farthing's was highly-commended. Lord Falmouth was an exhibitor in each of the Devon classes, but was not successful; as his lordship's best animals were kept back for Leicester, where, we hear, he will be in force.

The SHORTHORNS formed a very good section of the Show. Among the exhibitors were Lady Pigot and Mr. Stratton; but the prizes usually carried off by these far-famed prize-takers were on this occasion retained in Cornwall. Messrs. Hosken and Son's cows and heifers were much admired and extolled, and it is very questionable if so good a lot has ever before been exhibited from one herd at any of the Society's meetings. In class 6—bulls not exceeding four years old—there were only three entries. The competition was, however, severe between Lady Pigot's and Mr. Stratton's, opinion being divided as to the best animal. The first prize, however, was awarded to her ladyship's Charles le Beau, and the second to Mr. Stratton's Lamp of Lothian; Mr. Hosken and Son's Prince Frederick 2nd, bred by themselves, receiving a commendation. Had not the age been limited to four years there would have been more entries in this class, and we very much doubt the policy of the restriction. When the prize-list first appeared we were informed that this, and there being no class for yearling bulls, caused much dissatisfaction. We would also suggest the Society's offering a third prize in some of the classes. In class 7—bulls under two years—there were nine competitors. The judges selected five, viz., Lady Pigot's Rosolio, Lord Radnor's Orkney, Mr. Pollard's Lord Lyon, Mr. W. Trethewy's Duke of Cornwall, and Mr. Stratton's James 2nd, giving the first prize to Mr. Pollard's Lord Lyon, eight months old, a very thick and good red calf, with capital quality, got by Rectifier (22,887), grandsire 7th Duke of York (17,754); the second to Lady Pigot, and a high commendation to the Earl of Radnor. Although Mr. Pollard's calf was much admired, it was thought by many that Lady Pigot's should have been placed before him. In class 8—for the best cow—there were five competitors. Messrs. Hosken and Son exhibited three splendid animals, bred by themselves, and which would be no discredit to the Royal, and but for one or two of them being down-calving at that time, they would have put in an appearance at Leicester. Lady Pigot sent her Queen of Rosalia; but she was

beaten by Messrs. Hosken and Son's Rosebud, their other two cows, Countess and Carnation, being highly commended, and Rosalia taking second honours. In class 9—heifers not exceeding three years old—there were but three entries. The competition, however, was exceedingly strong between Messrs. Hoaken and Son's two heifers, Butterfly and Ruby, bred by themselves, and Lady Pigot's Dame of Rosalia. The Messrs. Hosken were, however, again eminently successful, winning both prizes, her ladyship being awarded a high commendation, at which her herdsman was indignant, and with very bad taste declined the proffered honour. The public opinion went with the judges. In class 10—heifers not exceeding two years—again there were only three entries, but the competition was very keen. The judges, however, preferred Lord Radnor's Darmstadt, and awarded the "blue ribbon" to his lordship; the "yellow" to Messrs. Hosken and Son's Keepsake, and a high commendation to Mr. Stratton's Bude Light. Messrs. Hosken and Sons received continued congratulations from their neighbours and friends on their well-merited success.

The HEREFORDS do not flourish much in Cornwall, and there were only six entries in five classes, and not one of these bred in that county. It should, however, be stated that Mr. Olver, an upholder of this breed, and who has on numerous occasions been a successful exhibitor, lost several of his cattle with the plague. In Class 11—aged bulls—there were only two entries; Mr. Duckham's Reginald easily winning the first prize, and Mr. Rawle Paramore being second. In Class 12—bulls not exceeding two years old—Mr. Paramore's was the only entry, and he was awarded the first prize. In Classes 13, 14, 15, Mr. James, of Dorset, was the only exhibitor, and to his cows and heifers were awarded the first prizes.

The show of LEICESTER sheep was very good, and in Class 16—yearling rams—the competition was very keen and spirited, the Cornishmen contending most successfully. Corner, of Somerset, exhibited four; Messrs. Norris, of Devon, three; Kingdon Radmore, two; G. Turner, two; Gould, four; G. Radmore, four; and Tremaine, of Cornwall, four; Rosewarne, two; and Clarke, one. The first prize was awarded to Mr. Tremaine, and the second to Mr. Rosewarne; but several good judges preferred the second to the first prize sheep. Messrs. Corner, Turner, and Gould had each a commendation. In Class 17, for aged rams, the competition was not so great, there being only fourteen entries and eleven exhibited. Mr. Gould deservedly carried off the honours, and won the first and second prizes; Mr. Turner receiving a commendation. The other exhibitors were Messrs. Kingdon Radmore and G. Radmore, Devon, and Messrs. Tremaine and Williams, of Cornwall. In Class 18, for yearling ewes, there were five entries, and the competition very close. Mr. Inner won the first prize, Mr. Tremaine second, and Mr. Corner a high commendation. The other exhibitors were Messrs. Norris and Gould.

The CORNWALLS, though not numerous, were well represented. In Class 19, for yearling rams, there were only eight entries. The competitors were Messrs. Gillet, who showed three; Beale Brown, three; and J. K. Tombs, two; the latter winning the second, and Mr. Gillet the first prize. In Class 20, rams of any other age, there were still less; but the class was a good one; the only entries being Messrs. Gillet, two; J. K. Tombs, two; and Beale Brown, one. The first prize was awarded to Mr. Gillet, for a remarkably large and good sheep, while Mr. Gillet had another commended; the second prize went to Mr. Beale Brown; and one from Mr. Tombs was commended. In Class 21, for yearling ewes, there were but three entries, and only one of them put in an appearance—Mr. J. K. Tombs's—and these were awarded the first prize.

In **SOUTHDOWNS**, class 22, for the best yearling ram, there were eight entries, but only five exhibited: Mr. Neville Greville, M.P., winning both prizes, whilst Sir Wm. Throckmorton's two sheep were not commended. In class 23, for rams of any other age, the first prize was awarded to Mr. Greville, M.P., and the second to Sir Wm. Throckmorton; there were four entries, but two only were shown. In class 24, yearling ewes, Lord Radnor and Sir William Throckmorton, were the only competitors, and the judges awarded the first prize to the latter for a very beautiful and even lot; his Lordship winning second honours. These classes were much admired; but the public thought the Hampshire, Shropshire, and Oxford Downs likely to yield a better profit to the farmer.

With the **HAMPSHIRE DOWNS** there was not much competition: Class 25, yearling ram, eight entries, and five exhibited: the first and second prizes were awarded to Mr. Rawlence, the other exhibitors being Messrs. Moore and Coles. Class 26, old rams, four entries, and two exhibited: Mr. Rawlence obtaining the first and Mr. Coles the second. Mr. Moore entered two sheep, but they were not sent. Class 27: Mr. Rawlence made two entries in this class, but only one lot was sent: the judges awarded him the first prize, and for the second there was not any competitor.

Amongst the **OTHER DOWNS**, class 28, for best yearling ram, Lord Falmouth exhibited four Shropshires, and Mr. Davy two; Mr. Wallis two Oxford Downs, and Mr. J. K. Tombs two. The first and second prizes were awarded to Mr. Tombs, who also won the second prize for the yearling Cotawold. Class 29, rams of any other age: Lord Falmouth exhibited eight Shropshires, and Mr. Wood one; Mr. Wallis two Oxford Downs, to which the first and second prizes were awarded, with eleven entries in this class. Class 30, yearling ewes, four entries and three competitors: The first prize was awarded to Mr. Wood's pen of Shropshires, and the second to Mr. Wallis' Oxford, the other competitor being Mr. Davey, whose pen of Shropshires were reared on land recently reclaimed from waste in Cornwall. The Shropshire and Oxford Downs have increased very much of late years, and stand high in the estimation of the public; why are they not entitled to separate classes and special prizes, as well as the Hampshire Down, Somerset, and Dorset Horn?

In the **SOMERSET AND DORSET HORN**, yearling rams, class 31, Mr. Mayo won the first and second prizes, the only other competitors being Messrs. James and Danger. Class 32, rams of any other age, three entries, viz., Mr. Mayo one, and Mr. Danger two, the former winning the first, and the latter the second prize. Class 33: There was more competition in this class, there being five entries and the same number exhibited; Mr. Mayo again winning first, and Mr. Danger second: the other exhibitor was Mr. James, of Blandford.

With **EXMOOR** and other horned mountain there was very little competition. In Class 34, rams of any age, there were only 4 entries and 3 competitors—Mr. Maunder winning 1st and 2nd prizes, the other competitor being Mr. Quartley. In Class 35, for pens of 5 ewes, 3 entries, the first prize was awarded to Mr. Maunder, the 2nd to Mr. Quartley.

In **DARTMOOR** and other moor, in Class 36, rams of any age, Mr. Drew, of Tavistock, was the only exhibitor, and he was awarded the 1st and 2nd prizes for two Dartmoor rams. In Class 37, pens of 5 ewes, only one entry by Mr. Drew, who was awarded the 1st prize for 5 Dartmoor ewes.

The pigs, although not numerous, were exceedingly good, the Messrs. Elmhurst, Duckering and Sons exhibiting in all the classes and taking most of the prizes. In the large breed, class 49, boars not exceeding two years old, only two entries, Messrs. Duckering and Sons

winning 1st and 2nd prizes. Class 50, boars not exceeding one year old, 5 entries, 8 competitors: Messrs. Duckering and Son won the 1st prize, and Mr. Widdicomb, Berkshire, the 2nd; the other competitor was Mr. King Tombs. Class 51, breeding sows in farrow or with litters: There were ten entries, Messrs. Duckering and Son won the 1st and 2nd prizes, and Mr. King Tombs was commended. Class 52, pen of 2 breeding sows not exceeding nine months old, only three entries: Messrs. Duckering and Sons 1st prize, Mr. Williams, M.P., 2nd, and Mr. King Tombs commended.

In Pigs, of the small breed, Class 53, best boar, above one year and not exceeding two years old, four entries and four competitors, the first prize was awarded to Messrs. Duckering and Sons; the second to Mr. Coles; the other competitors being Lord Radnor and Mr. Davey. In Class 54, boars not exceeding one year old, two entries only: First prize, Messrs. Duckering and Sons; the second, Mr. Davey. In Class 55, best breeding sow, five entries and five competitors, and an exceedingly good Class, the first prize being awarded to Mr. Collier, of Devon; second to Messrs. Duckering and Sons, whilst their other sow was highly-commended; and Mr. Davey and Mr. Coles each receive a commendation. Class 56, for the best pen of two breeding sows, five entries and five competitors: this was also a very good class; Mr. Cornish, of Devon, winning the first prize; Messrs. Duckering and Sons the second; whilst Lord Radnor is highly-commended, and Mr. Davey commended.

The **HORSE** department of the show was by no means good. The Society offers no prizes for thorough-bred stallions, and the horse division of the prize-list has in this and other respects been sadly pared down; moreover the Society's charges operate against a good entry. The Royal Cornwall Agricultural Society had a much better show of horses last year at Launceston than the Bath and West of England could command on this occasion. There were four classes for horses and mares for agricultural purposes, with eight prizes, and yet there were only nine entries, and two of these were disqualified by the judges. The first prize for stallions in Class 38 was awarded to Mr. Laity, of Camborne, Cornwall—a very useful cheesnut bred by himself; and the second to Mr. Brydges Williams for a cheesnut Suffolk stallion. In Class 39, for the best stallion foaled in 1866, there were only two entries, and the judges deemed one not worthy of a prize: the first was awarded to a splendid two-year-old, bred by and the property of Mr. Hitchcock, of Heytesbury, Wilts. In Class 40, for best mare and foal, the judges disqualified both animals for being entered in wrong class, as more adapted for general purposes. In Class 41, for the best filly foaled in 1866, no entry. In the four classes for Hunters there was nothing particularly worthy of note, except Mr. Battams's cheesnut gelding The Don, and his brown gelding Slapton, these winning the first prizes in their classes. In Class 42, best mare or gelding foaled before 1st January, 1864, two entries, Mr. Battams first prize, and Mr. James, St. Mawes, second. In Class 43, best mare or gelding foaled in 1864, four entries, first and second prize Mr. Battams. In Class 44, best mare or gelding foaled in 1865, four entries: first prize to Mr. Michelmores; second, Mr. Carne. In Class 45, best colt or filly foaled in 1867, seven entries: this was a pretty good class; Lord Falmouth receiving first prize, and a high commendation for another; the second to Mr. Laity. In Class 46, for Hacks, best mare or gelding not more than six years old, nor exceeding fifteen hands high, four entries: Mr. Battams winning the first prize, and Mr. Williams, of Pananuworthal, Cornwall, the second. In Class 47, for Ponies, the best mare or gelding, not exceeding

fourteen hands high, two entries, one only shown: the first prize awarded to Mr. Smith, of Bradford Peverill, Dorset. Class 48, the best mare or gelding, not exceeding thirteen hands high, five entries and five competitors: This was a very good class, and excited great interest, the animals being justly much admired, particularly Mr. Gay's white Ermoor, Gem, to which the first prize was awarded; Mr. Collier receiving second, Mr. Michelmores highly-commended, and Mr. Arthur Williams commended. There is no question but that the prize-list for horses requires some radical revision.

The POULTRY SHOW was very good.

Judges: Cattle, Mr. R. Warren, Blandford; Mr. J. Weppell, Exeter; Mr. Savidge, Saraden, Chipping Norton. Long-woolled sheep and large pigs: Mr. Sanday, Holme Pierrepont, Nottingham; Mr. J. Partridge, sen., Hilldown Bow, North Devon. Short-woolled sheep and small pigs; Mr. J. Ford, Rushton, Blandford; Mr. F. Budd, Hatch Warren, Basingstoke. Horses: Mr. H. Thurnall, Royston; Mr. H. Terrell, South Brent, Ivy-bridge, Devon. Poultry: Mr. E. Hewitt, Birmingham.

In point of excellence of articles exhibited, we believe the show to be nearly up to the average; and certainly the display of implements and machines is of much greater extent and practical value than we anticipated would have been the case in view of the extreme distance which exhibitors from the making districts have to bring their exhibits. The number of exhibitors is nearly one hundred; the number of entries, thirteen hundred and thirty-one; exceeding by some four hundred the entries for the Truro show held in 1861. The number of sheds is fifteen, including one 300 feet in length, for the exhibition of machinery in motion; the whole run of shedding extending to two thousand seven hundred and ninety feet.

In going over the stands we shall take them in the order as they present themselves on entering the yard, or rather on turning from the offices. And the first which attracts our notice is the collection of seeds and farm produce of Messrs. Sutton and Sons, of Reading, Berks. The practical and suggestive value of this collection may be gathered from the statement that it is comprised in a shed one hundred feet in length, and that it embraces upwards of one hundred-and-fifty varieties of grasses, about one-half of which are growing, at least have been brought directly down from the experimental beds at Reading, and from being carefully rooted in soil are fresh and vigorous. The collection of seeds is also very valuable, presenting samples of upwards of one thousand varieties. The centre case is part of that very complete one which was exhibited in Paris at the Great Exhibition of last year, and for which was obtained the first prize. We may also take special note of the remarkably fine specimens of mangolds, in fine condition, thoroughly sound. There were Sutton's long red, the large intermediate yellow-globe, and red globe. The garden seeds were well represented. We have above alluded to the specimens of grasses, natural and artificial, exhibited in their growing state; and as these were all or nearly all at their flowering stage, they presented the most practically useful examples which could be obtained. We are glad to see the Messrs. Sutton paying attention to the proper development of this branch of rural economy; for it is one in connection with which there is a wide field for useful operation. The improvement of old and the laying down of new pastures and meadows, is one of the most important branches of agricultural economy, and although much has been done of late in this direction, it is not too much to say that more remains to be done.

The next collection of seeds and farm produce is that of Carter and Sons, High Holborn, London. Here is exhibited a very extensive collection of farm, garden,

and flower seeds; 300 samples of corn seed, also of corn in the ear; and samples of the permanent grasses, for which Messrs. Carter received the prize at the Paris Exhibition of last year.

Next to the Messrs. Carters' stand was that of Mrs. Mary Lyne Pontey, of Plymouth, who exhibited a pretty large collection of farm and garden seeds, specimens of grasses for pastures and meadows, and of roots—as Fisher Hobbs' orange globe mangold, a root of smallish size, but of good shape and quality.

Passing to the centre of the field, in which the implement sheds are placed, and taking them in their order as we proceed towards the sea, we find first the stand of Messrs. Samuelson, of Banbury, the principal feature of which is the number of mowers and reapers exhibited. Amongst these we noticed the reaping machine with self-raking and side-delivery. This machine presents the same features which characterised it at the shows of last year, at which it was exhibited, although several improvements in detail have been introduced. The self-raking movement is very ingenious, being effected by the end of the arm of the rake moving over an eccentric path, the course of which is so arranged as to give the necessary movement to the rake as it sweeps across the delivery platform—which is curved in outline, so as to deliver the swathe at the side—first bringing down the rake from its highest point to gather in the corn to the knives, to sweep more or less horizontally across the platform, and then to rise up clear of the corn after delivery. In the one-horse reaping machine, the delivery is manual, and at the back, being effected by a moveable platform, or rather open rake table, hinged at one side to the machine, and capable of being lifted up by a lever and pedal movement, acted upon by the foot of the attendant who sits upon the machine. The corn is brought up to the knives by a hand-rake. In adapting this machine for cutting clover and seeds, a swathing apparatus is added. By a simple arrangement of lever the cutter-bar and platform are lifted up in turning the machine; and the height to which the cutter-bar is raised from the ground is adjusted by a screw and chain. In the grass-mowing machine there are some points of excellence worthy the attention of the purchaser. Of these we would direct his attention to the simple form of clutch by which the cutters are thrown in and out of gear; and the very effective and ingenious spring movement, worked by the foot of the attendant who rides along with the machine, by which the cutter-bar is adjusted so as to meet the inequalities of the ground over which the machine passes in its working.

The stand next come to is that of Bentall, of Heybridge, Essex, in which is exhibited a small but good collection of the specialties for which Mr. Bentall is so well known, as his chaff-cutters, oilcake-breakers, turnip-cutters, and root-pulpers. This latter class of machinery is constructed upon such correct principles that we do not wonder of its having maintained its high reputation during a now considerable course of years. We believe we were the first in the columns of the present Journal to give a detailed description of the movements of this machine, and the position it has since taken and maintained have justified the high opinion we then formed of and expressed about it.

One of the most extensive, if not the most extensive, collection of machines exhibited by makers from a distance, is that on the stand of Pickley and Sims, of Leigh, Manchester, and which comprises examples in various sizes of his chaff-cutters, oilcake-breakers, root-cutters, and pulpers, with lawn-mowers, and horse-rakes. The horse-rake is made with a straight shaft, through from side to side; and the lifting movement is simple, and easily worked. A novelty is exhibited in the form of a new reaping machine, the

pincipal feature of which is the construction of the knife; the finger-bar has the fingers screwed on at the receiving intervals, and steel blocks are fitted in behind these. The whole of the upper surface presented by these blocks and the end of the fingers is perfectly flat, with sharp edges at the sides of the fingers; and being made of cast-steel of the finest quality, the lower surface of the cutters or knives work against it, and thus tend to keep the cutting edges continually sharp. The form of the fingers also prevents choking.

In the next stand, Brenton, of Polbathic, St. Germans, Cornwall, exhibited his patent cylinder reaping machine. This has a side delivery, the platform being curved; but it is terminated by an obliquely out end, against which a roller or cylinder revolves; this is conical, the smallest end being nearest the working gear, the longest at the furthest end of the delivery platform. The patentee claims for this arrangement a strengthening of the machine, and a regular sheaf delivery of the corn. The travelling or bearing wheel are of considerable diameter, and the gearing is simple in character. A reaping machine is also exhibited with back delivery, the rake platform being worked by the foot of the attendant.

The stand next arrived at in our ramble through the sheds is that of Messrs. Howard, of Bedford, who have a very large collection of their well-known implements and machines. Amongst these we particularly noticed their mowing and reaping machines, in both of which very considerable improvements have been effected since their last public appearance at Smithfield Show in Christmas of 1867. The same remark applies also to their boiler, which, we are glad to know, is rapidly assuming a high position in this important department of steam appliances. We are, however, not by any means surprised at this, for from the very first practical examination we made of it, and the results of which we gave in a special report upon it in the pages of this Journal, we saw in it so many features of excellence that we had no hesitation in claiming for it a high position amongst modern and recent inventions. We look upon this as forming the most important improvement of recent times in boiler-construction; and it is just because we have for so long been impressed with the high importance of this department that we so strongly express ourselves in relation to it. A few remarks as to the improvements recently made by the Messrs. Howard will not be out of place here, and first as to the reaping machine. The first peculiarity which strikes one on examining this machine is the two driving-wheels with which it is provided. We believe this to be a sound mechanical arrangement, inasmuch as it not only ensures thorough general steadiness of action, but it tends to keep the knives in full action in nearly all positions in which the machine is placed. It also gets rid of the necessity for having a side draught, the draught-pole being placed in the best position to secure a direct, and a consequent lightness of draught; and, further, the balance of the whole is so perfect as to keep all weight which might otherwise arise from oppressing the horses. This arrangement also permits of a form of framework which is well calculated to secure several advantages. The cutter-bar is winged or jointed to the side of it, and it thus can readily accommodate itself to the inequalities of the ground, and the whole of the framework can be very readily freed from the platform and rake in passing through gates, or on being stored up in the implement shed. The points connected with the cutter-bar now come under notice. This is placed behind the driving-wheels, which position enables it to pass easily over obstructions, and the bar is provided with a raised projection upon which the knife works to and fro; this raised part allows the dirt and soil to fall freely away from the cutting parts. The fingers have a clear space between them, which is advantageous

in low cutting. The driving-gear for the cutter-bar is well arranged; the crank is brought down low, to admit of its working in almost a direct line with the cutter-bar, and a combination of bevel with spur gear is used to drive the cutter, the first slow motion being taken off the main driving wheel by means of bevel wheels, the second rapid motion being taken off by spur-wheel gear, the employment of which by the way affords facilities for quickly changing the speed of the knife, this being done by simply altering the spur wheel. The self-acting gathering rake is drawn by special apparatus, thus being independent of the driving gear for the cutters. The gathering arms revolve in an inner cam, which has its curves very abrupt, changing from a very low to a very high line. The blades are brought down as low as the points of the rakes, and bring in the corn to the action of the knives. Having performed this, the gatherers rise very suddenly, so as to be kept perfectly clear of the grain, and the rake is next brought into action, and sweeps the grain off the platform in sheaf, the size of which can easily be regulated by altering the gearing of the gathering apparatus. The mowing machine is very similar as respects its driving gear to the reaper just described; of course, a higher speed of knife or cutter-bar is provided for. The fingers are raised or lowered according to the nature of the ground by means of a lever, another being provided by which the cutter-bar can be raised in passing over mole-hills or other obstructions. The cutter-bar is put in and out of action by a lever worked by the foot of the workman. A description of the boiler has already appeared in our columns.

The next stand is occupied by Messrs. Kearsley, of Ripon, Yorkshire, who exhibit their mowers and reapers. They exhibit a novelty, recently patented, in a new mode of attaching the end of the connecting-rod which works the cutter bar to the crank wheel, and the object of which is to prevent, by any extra pressure which may come upon the cutter bar, the jamming up the knife eye or crank-pin. This is effected by a very ingenious and simple modification of the ball joint. The crank-pin, which is hollow, passes through the centre and is fixed to the ball joint, the spherical or partly-spherical surface of which plays in a corresponding hollow or cup turned in the face of the wheel to which the crank-pin is connected; and the whole are secured together by a washer, bolt, and nut. Any undue pressure which tends to throw the connecting-rod out of the direct line is got rid of by the crank-pin giving and taking, the ball joint moving in its cup or socket, admitting of a lateral play more or less, according to the pressure brought upon the connecting-rod. The crank is made hollow, and a diagonal slot, cut in it admits of the oil, with which the hollow of the pin is filled from time to time, being passed to the moveable joint, which is thus kept well lubricated. A supply of oil can be conveyed by the hollow crank-pin equal to several hours' working—five or six.

L. L. Larksworthy and Co., Lowmoor Iron Works, Worcester, exhibit various articles, as ploughs and harrows; and Messrs. Garton and King, of Exeter, their cooking stoves and seats. The same firm have also stalls, and a loose box fitted up with their improved fittings, in connection with which there are exhibited a good many stable appliances.

Going up the field we come to the stand of Colthurst, Symons, and Co., of the Patent Tile Works, Bridgewater, who exhibit a goodly collection of tiles, pavements, and amongst the former specimens of Beadon's patent Gothic tile, an excellent and cheap contrivance for forming eaves gutters, and to which we have on other occasions specially referred. Passing the Arts Department, and following the course of the field, we take the row of sheds next the sea, and work our way back again to the

entrance, at which point we began our labours. In this arrangement of our work, the stand we first come to is that of Parkham, Northgate Street Iron Works, Bath, who exhibits a good collection of hurdles and gates. And, by the way, referring to gates, we may remark that in many cases a remarkable overlooking of the principles upon which they should be constructed is to be found in many gates exhibited at our shows. The subject is one of importance, and will bear investigation in a special paper, which we purpose shortly devoting to it.

The stands next in order contain exhibits, the majority of which, not being specially connected with agriculture—at least not requiring much special description—may be noted in one paragraph. The exhibits are Beach's (Dudley, Worcestershire) cattle-food; Hepburn's (Long-lane, Southwark, London) leather belting; Gliddon's (Wilton, Taunton) prize ranges, who also exhibits a screw-driver water-tap, showing considerable ingenuity in the means by which leakage is prevented, this being effected by a double screw and flat washer-valve; G. Dodge's (London) vulcanized India-rubber driving bands, tubing, and waterproof sheeting; Cook (Redruth, Cornwall), dog-carts; the Bovey-Tracey (Newton Abbott) Pottery Company, fire-brick and tiles; Bullay (Station-road, Plymouth), miniature brougham; Terrill (Redruth, Cornwall), cooking range; T. Pethick (Tamerton Folliott, Plymouth), farm carts; Hardon (Albert Works, Strange-ways, Manchester), royal patent feeding cake; Richard Cragge Silvester (16, St. James's-walk, Clerkenwell, London), American inventions, &c., a knife sharpener, a nose-ring for cattle, and a weighing-scale; Baker (Compton, Newbury, Berkshire), liquid manure carts, and pump; Day, Son, and Hewitt (22, Dorset-street, Baker-street, London), medicine-chests, gaseous fluid, &c. Bradford—the ubiquitous Bradford—of Cathedral Steps, Manchester, turns up here, as at every show, with his washing-machines, which, as Josh Billings would say, "are, in course, poorly agyerkateryil mashins," which have fantastic designations as "Vowel" machines; why so-called we cannot say. But he has here something specially agricultural, and which deserves more than a passing notice: it is a churn, which, as usual with this indefatigable inventor, he designates fantastically, and it therefore figures as the "C.C.C." churn. Whether there is a hidden or occult pun in this, we know not; but the sound, at all events, conveys a hint to look at it. And really it is worthy of being looked at, as it possesses considerable claims to being what seems all the rage at present, an aerating or atmospheric churn. The principal feature lies in the form of the dasher, or rather plough, for the milk is acted upon by the reciprocatory motion, like the old-fashioned plunge-churn, which is square or rectangular in form. Its extremities or side-wings, as we may call them, are simply hollow boxes, the outer sides of which are quite open, although the upper part or lid and the sides and ends are closed. These boxes do not stretch right across the whole of the plunger, but are stopped short, leaving a space between them. This space is filled up with square bars set diamond form, thus . The plunger thus constructed is provided with two cross-bars, to the centre of which one end of an upright lever is jointed, the upper end of which is jointed to a horizontal cross lever placed some distance above the top of the churns, and one end of which is grasped by the operator, the other end being jointed to a vertical support at the back. The operation is as follows: The box in which the plunger is placed is filled to a certain height with the milk or cream to be operated upon, and the plunger lifted sharply up, till the lower edge of the side-wings or boxes of the plunger are a little above the surface of the milk or cream, the air then passes into and fills the spaces of the boxes, when the plunger

is forced down into the liquid, and the air is passed through it, and up between the churn and set bars, the shape and position of which cause a variety of contrary currents, which agitate the liquid. Whatever other result is obtained, that of passing a large body of air through the liquid is certainly obtained: a very short working of the churn suffices to show that. We believe trials have shown its value in practice, and certainly nothing can be fairer than the terms upon which the inventor offers it to the public, for he gives intending purchasers a month's trial of it, and if that does not satisfy them, he takes back the churn. Our description is complete when we give the poetical quotation with which the inventor heads his prospectus, and which is applicable to more things than to churns:—

"The current that with gentle murmur glides,  
Thou knowest, being stopped, impatiently doth rage."

Shakespeare, from whom this is taken, has been called a "universal-minded man;" it must be so, else he could not thus have been pressed into the service of agricultural implement makers, to, slightly altering the quotation, "point their prospectus, and adorn their tale."

The attendance during the two first days, Monday and Tuesday, both of which have been half-crown days, has not by any means been great; but we believe the pecuniary result has satisfied the Society—at least such is what common report says, if that is trustworthy. On Monday 659 paid for admission, 1,800 yesterday, but the number admitted to-day (Wednesday) must reach some thousands, for already, at the early hour we write this, crowds are pouring in from all quarters. The weather is beautiful, and the attraction outside the show as well as inside cannot fail to bring a large concourse of people. If, in addition, to the money they bring to the Society, they bring also business to the exhibitors—which up till to-day has been exceedingly dull—all concerned will have no reason to complain.

On Tuesday forenoon, about eleven o'clock, the trials of mowing machines was begun on a field of rye grass, in the immediate neighbourhood of the show-yard. The trials excited great interest, and were attended by a considerable number of visitors to the show. The Bath and West of England Society have for some years given up the prize system, and that trials such as were carried out on Tuesday and Wednesday were not trials in the ordinary sense of the term, as involving any competition for prizes or other marks of merit. The Society takes no cognizance of them, but simply affords facilities for carrying them out, and takes the general management of them such as they are; leaving the public who witness them to be the best judges of the results. It is, to say the least of this arrangement, open to discussion as to whether it is a wise policy on the part of the Society; whether, indeed, it is not an ignoring of one of the duties of an agricultural society—namely, that which imposes upon it the task of ascertaining for its members what are the inventions and appliances which are likely to be useful to them in their practice. Those are not few in number nor unimportant in influence who maintain that this is one of the duties, possibly the most important, which an agricultural society has to perform; and, if so, it is difficult to see why this Society has foregone its performance. We cannot but think the decision of the Bath and West of England Society an unfortunate one. The prize system has unmistakably done much good, and is still capable of doing good; and there is one commentary very striking, to be met with in the show-yard itself, upon the decision of the Society, with reference to the doing away with the prize system in connection with the implements and machines. A walk through the stock and poultry departments will show on every side tickets

blazing forth "First prize," "Second prize," "Third prize," and so on. How is this? Is the prize system so good for one department that it is followed out; so bad for another that there it is condemned, and thrust aside as worthless, if not worse? We do not lose sight of the fact that there are conditions affecting the stock prize system which do not affect—at least in the same degree—the prize system connected with implements and machines; nevertheless, to many it does seem an anomaly that prizes should be given in one and not in another department. It is scarcely the place—certainly not the place to do the subject justice—to take up the discussion of this question at the end of a long article. Meanwhile, we feel that we should not have been doing either our readers or ourselves justice had we not alluded to it, and very clearly given our opinion upon it. We now conclude by giving the list of those who tried their machines on Tuesday. The numbers refer to the numbers of the plots which the different competitors—if the term is allowable when nothing was competed for—drew for the choice of plots. (5) Walter A. Wood, (1) Samuelson and Company, (4) Brenton, (7) Reading Iron Company, (2) Hornsby and Sons, (9) Burgess and Key, (10) Beverley Iron and Waggon Company, (6) Pickles, Sims, and Co., (8) Howard of Bedford, (8) Kearsley, (11) Bamletts. The trials excited great interest, and a slight shower before and after and during the trial made the grass in capital order for working. As a rule, the work done by all the machines was excellent, although to some the usual mishaps occurred, which prevented them from displaying their full powers. It would be invidious under the circumstances to enter into a detailed account of the work done by the various machines: that will be probably done when more leisure awaits us. On Wednesday the reaper trials were being carried on in a field of rye some distance from the Show-yard. The crop is in excellent condition for displaying to advantage the capabilities of the different machines entered for trial, the principal entries being made by Burgess and Key, Howard, Wood, Brenton, Kearsley.

### THE IMPLEMENT STANDS.

**HOLMES and SON, Norwich.**—Seven-horse power portable steam-engine; combined prize portable finishing thrashing machine; improved circular-saw table; eight, ten, and fourteen-row corn and small occupation drills; four-row and economical West of England seed and manure drills; broadcast corn and seed-sowing machine; single and two-row turnip and mangel drills; and corn-dressing machines.

**TASKER and SONS, Andover.**—Six-horse power portable single cylinder steam-engine; single-blast patent combined portable thrashing machine; screw-lifting jack; corn-dressing machines; oilcake breakers; and circular-saw tables.

**CLAYTON, SHUTTLEWORTH, and Co., Lincoln.**—Five and six-horse power single cylinder portable steam-engines; single and double-blast combined thrashing and finishing machines; and patent combined two-row revolving liquid manure and drop drill for turnip and other seeds.

**POWIS and Co., Millwall.**—Improved mortising, tenoning, and boring machine; improved endless band sawing machine; the "Joiner Universal" sawing machine; improved three-cutter moulding machine; improved self-acting circular saw-bench; and a portable steam-engine to drive the foregoing machinery.

**THE READING IRON WORKS (LIMITED), Reading.**—Three-horse power portable steam-engine; two patent "clipper" mowing machines; improved lever horse rakes; gorse-bruising machine; improved chaff-cutters for hand and horse power; oilcake mill; grass seed broadcast sowing machine; and forty-two inch combined portable thrashing machine.

**BROWN and MAY, Devizes.**—Eight-horse power patent portable steam-engine; and four-feet six-inch combined finishing thrashing machine.

**MARSHALL, SONS, and Co., Gainsborough.**—Five and eight-horse power portable steam-engines; combined thrashing and finishing machines; and improved circular-saw benches.

**PLENTY and SON, Newbury.**—A patent engine and boiler yachts, launches, and other boats.

**HAWKEN and CLEMOW, St. Iseey and St. Merry, Cornwall.**—Ten-horse power double-cylinder portable steam-engine; eight-horse power single-cylinder portable steam-engine; combined portable double-blast finishing thrashing machine; improved circular-saw bench (new implement), with cast-iron frame and planed table; improved chaff-cutting machine; (new article), set of steadying blocks; combined reaper and mower; self-raking, "Eclipse," and governor self-raking reapers; improved horse-gear; turnip-cutters; an assortment of "Excelsior" turnwrest and other ploughs; an iron plough (new implement), made with wrought-iron centre-piece introduced in the beam, and wrought-iron frame; collections of hay and dung forks; leather machine bands, and vulcanized india rubber bands; patent flexible or chain harrows; and collection of oil feeders, &c.

**THE BEVERLEY IRON and WAGGON COMPANY, Beverley.**—Two-horse grass mowing machine; one and two-horse reaping machine, with manual and double self-acting swathe delivery; three pairs of patent cart wheels, with axles, to carry 20, 25, and 30 cwt.; Newcastle prize or one-horse model cart; self-cleansing clod crusher and roller; and a pair of cast-iron wheels for clod crusher or roller.

**RUSTON, PROCTOR, and Co.**—Five and six-horse power portable steam engines; single and double blast thrashing, finishing, and dressing machines; and improved circular-saw bench with planed metal table.

**HUMPHRIES, Pershore.**—Six-horse power portable steam engine; combined thrashing and finishing machine; and pair of two-and-a-half inch cider press screws.

**HORNSBY and SONS, Grantham.**—Six-horse power portable steam engine, with contracted steam chamber; four-feet combined thrashing, shaking, and finishing dressing machine; "Governor," "Premier," and "Plymouth" self-raking and one-horse back-delivery reaping machines; patent "Paragon" mowers, and "Plymouth" and "Paragon" combined mowers and reapers; an assortment of light and strong two-horse iron ploughs; root-pulpers; patent washing machine with wringer and metal screw; improved patent mangle with brass-capped sycamore rollers; patent 10½-inch forked leg wringer, with metal screw; and ten-row corn and seed drill.

**GARRETT and SONS, Saxmundham.**—Four and six-horse power portable steam engines; combined thrashing and finishing dressing machines; patent straw elevator; ten and eleven-row Suffolk corn drills; West of England and other pattern corn and seed drills; two sizes of Chambers' patent artificial manure distributor; improved horse hoes; corn dressing machines; and patent rick and corn ventilators.

**SUTTON and SONS, Reading.**—Collection of one hundred specimens of dried grass, plants, and samples of grass seeds; complete assortment of the principal kinds of agricultural, horticultural, and floricultural seeds; collection of agricultural roots; and growing samples of various kinds of seeds in pots.

**BEALE (CARTER and Co.), London.**—Samples and specimens of natural grasses for permanent pasture; wheats, barleys, oats, mangel, turnip, and other agricultural produce.

**PONTREY, Cornwall.**—Collections of approved kinds of seed, grasses, and field roots, including mangolds and turnips.

**SAMUELSON and Co., Banbury.**—Self-raking and one and two-horse "Eclipse" reaping machines; two-horse grass mowers; combined mower and reaper; and fourteen, nineteen, and thirty-inch lawn mowers.

**BENTALL, Maldon.**—Five specimens of patent chaff cutters, of various power, for hand and horse working; improved disc root pulpers; Gardner's turnip cutters; and improved oilcake mills.

**ROBERTS and SONS, Bridgewater.**—The patent "Economist" carriage; waggonettes; park phaetons; Malvera, Whitechapel, and other dog carts; a gadabout Dennet gig; and miscellaneous lot of single and double harness.

**PICKSLEY, SIMS, and Co., Leigh.**—Variety of different size chaff cutters for hand and horse power; steel grinding mills; oat and bean mills; smooth roller crushing mills; single and combined turnip pulpers, slicers, and strippers; Gardner's single action turnip cutter; new pattern oilcake

mill; eleven, thirteen, fourteen, and nineteen-inch lawn mowers; single and double cylinder garden rollers; an assortment of combined wood and iron garden pic-nic chairs, of various sizes and patterns; American and improved horse rakes; case of American hay and manure forks; twelve pig troughs, assorted sizes; two-horse mowing machines; two-horse combined reaper and mower; and one-horse "Champion" reaper.

GOSS and SOX, Plymouth.—Specimens of brass and steel letters for marking and branding purposes; and ornaments, coats of arms, and trade marks for all kinds of metal, wood, &c.

BRENTON, St. Germans, Cornwall.—One and two-horse patent cylinder reaping machines; two two-horse "Nonpareil" mowing machines; three-row turnip and mangold drill; combined blowing and dressing machine; broadcast corn and seed machine; improved registered sheep rack mounted on iron wheels; set of tubular iron whippetrees; samples of machine driving bands; and bundle of hay and manure forks.

HOWARD, J. AND F., Bedford.—An assortment of iron one and two-wheel iron ploughs for every variety of soil and work, with subsoil, ridging, and digging-bodies for attachment; improved potato-raising plough, with two wheels and double raisers; improved plough sledge, dynamometer or draught gauge, sets of patent flexible chain and beam iron harrows, improved wrought-iron harrow carriage, sets of trussed whippetrees, patent horse rakes, three sizes patent double-action hay-making machines, new patent improved two-horse mowing machine, one and two-horse manual and self-delivery reaping machines, and new patent safety steam boiler and super-heater of ten-horse power.

KEARALEY, H. AND G., Ripon.—Two-horse grass mowing machine, two-horse combined mower and reaper, one and two horse reaping machines, and a meadow mower.

LARKWORTHY AND CO., Worcester.—Three sizes patent "Excelsior" iron ploughs; various sets of "Excelsior" iron scuffles, drag and beam harrows; sets of "Excelsior" steel plough and equalizing whippetrees, and a wrought-iron cattle crib.

GARTON AND KING, Exeter.—An assortment of cottage, domestic, farmhouse, and pedestal cooking stoves, ranges, grates, and heaters; variety of useful and highly-ornamental combined wood and iron garden seats and tables; set of cast-iron work for loose box, porcelain manger and drinking trough; sets of cast-iron stall divisions and stable fittings; cast-iron galvanized hay-racks and corner mangers; single and double harness fittings, and general stable necessities and utensils; wrought-iron gates with posts and stays, wrought-iron hurdles, continuous cattle chain fence and galvanized strained wire; wrought-iron cylindrical boiler, and cast-iron crescent boiler.

BORT, Bury St. Edmund's.—Five patent double-action hay-makers, fitted with wood or iron travelling wheels; patent corn screens, with blowers and removable wire beds; improved patent barley screen, improved corn-dressing machine and screen combined, improved malt screen, barley and malt hummellers; patent self-acting horse-rakes, with seat for driver; and patent oval-beam iron and wood-beam ploughs.

TUCK AND SON, Bath.—Patent and improved Hornblotten and Chantry stiles, in oak and iron; lengths of five-wired, continuous, and tubular cattle fencing, with straining pillars; specimens of wrought-iron field and garden gates, hurdles, and verandahs in different panels; selection of garden seats, chairs, tables, watering engines, and wheelbarrows; models of cast and wrought iron boilers; model of arrangement for heating churches or public buildings; and model of gasworks for mansions, factories, collieries, &c.

WHITE, London.—Specimens of the patent S. L. V. oil-feeders, save-all, pyramid oil-cans, needle lubricators, artificial dams, stable and barn lamps and lanterns, and thatch fasteners; and samples of leather driving bands, straps, lashing laces, and thongs.

MUSGRAVE BROTHERS, Belfast.—Four full-sized horse-stalls, with patent fittings; a variety of fittings and stable furniture, racks, mangers, &c.; patent iron cowhouse fittings, dog kennels, and piggeries; patent harness-room, slow combustion, and conservatory stoves; and an assortment of stable utensils and necessities.

PLIMSAUL BROTHERS, Plymouth.—Improved one-way and other ploughs; turnip hoes; flexible, chain, and Bedford harrows; improved American tubular, iron, hand and horse rakes; patent self-raking and one-horse "Eclipse" reaping machines; combined reaping and mowing machine; double and single

action hay turners; chaffcutters of various power; improved turnip pulpers, strippers, and slicers; Gardner's single and double action turnip-cutters; improved oat, bean, corn, seed, and malt crushers; two and three row turnip and mangold drills; corn dressing and blowing machines; an assortment of liquid manure barrows, pumps, and garden rollers; washing, wringing, and mangling machines; garden chairs, engines, flower-stands, &c.; selection of spades, scythes, and forks; an assortment of lawn mowers and rolling machines; galvanized iron cattle, pig, dog, and poultry troughs; American cottage and domestic cooking stoves and ranges; a variety of gas-burner stoves, with flexible tubing; a variety of cooking pots and domestic utensils; Milner's patent fireproof boxes and safes; stable fittings and furniture; corn measures, weighing machines, garden tools, knife-cleaning machines, and cask of sheep wash.

CARSON AND TOONE, Warminster.—An assortment of chaff-cutting engines for hand, horse, or steam power; Moody's patent turnip-cutters, on iron frames; oilcake crushers; single and double cheese-presses, on iron and wood stools; and an assortment of wrought-iron horse-hoes, with three steel hoes and five tines.

BAKER, Wisbeach.—Improved combined blowing and dressing machines, and combined corn-dressing machines with one hopper.

THE CANADIAN WASHING-MACHINE AND AGRICULTURAL IMPLEMENT COMPANY, Worcester.—Patent Canadian washing-machines, with wood and iron frames; two sizes of compound lever mangles; patent combined washing, wringing, and mangling machine; India-rubber wringers; patent clothes-horse and dryer; and sets of improved diagonal-shaped three and four-beam harrows.

SARA, Penryn, Cornwall.—Twelve-horse power horizontal steam-engine; pair of 12-horse power vertical engines, with reversing motion; 2-horse power small donkey engine and boiler; steam-ram for forcing water; sets of three chaff-cutters; and set of four ploughs.

NICHOLSON, Newark-on-Trent.—Three haymaking machines, with single and combined motion; (new implement), high-wheeled horse-rake, of great height, and constructed to carry large loads; 24-inch garden roller, with double cylinders; patent cake crusher; registered bottle racks to hold six and twelve dozen; sack-lifting machines; malt and corn shovels; and Baker's patent anti-incrustator.

BLANSOMES AND SIMS, Ipswich.—An assortment of iron beam two wheel, moulding, ridging, turn-wrest, or one-way ploughs, for every variety of soil; ridging, subsoil, potato, and digging bodies; sets of trussed iron whippetrees and pomel-trees; improved horse-rake; set of three patent-jointed harrows; bean-cutter; oat and combined mills; oilcake breakers; Gardner's turnip-cutters; root-pulper, for hand power; and four "automaton" lawn-mowers.

BURGESS AND KEY, London.—Reaping and mowing machines, and combined reaper and mower.

BUCKINGHAM, Llannecon.—Champion butterfly ploughs; seven-tined cultivator; (new article), a cultivator with nine tines, for large occupations, to cover six feet of land; and an improved horse-hoe.

DENING AND CO. (late Wightman and Denning), Chard, Somerset.—Haymaking machines; horse-rake; cheese-press; apple mill and corn-bruiser; three sizes of horse-gear; iron ploughs for light and heavy land; root-grater; and horse-hoe.

WILCOCKS, Bath.—Three, four, five, and six-motion beer-engines, with fittings complete; gas-cooking stoves; bottling machine, for soda-water manufacturers; soda-water cylinder or condenser; atmospheric kettle-boilers and kettles; two and three-light chandeliers; harp lamp; and set of pewter wine measures.

EASTWOOD, Blackburn.—An assortment of patent compound-action churns, in sizes to churn from one to eight gallons.

BAMLETT, Thirsk.—Two-horse grass mower, and one-horse reaper.

THE BRISTOL WAGGON COMPANY, Bristol.—Light crank-axle, improved farm, and pony or errand carts; Wood's one and two-horse mowing and reaping machines, and combined mowing and reaping machine; three sizes of American horse-rake; patent steel-tooth hay-collectors; grass seed distributor;

five and six-row corn-drills; patent and improved sheep-rakes; and improved road-scraper.

LE BURR, Bury St. Edmund's.—Four patent "Champion" double-action haymaking machines; (new implement), registered self-acting hand seed drill, for producing greater regularity in sowing seed; an assortment of mower or reaper-knife rears; everlasting malt-screens; and (new article), specimens of the Abercorn chair, which by a simple movement is instantaneously converted into a pair of useful steps.

PARNELL AND SON, Exeter.—A variety of gig and other harness, saddles, bridles, snaffles, Martingales, &c.; whips, canes, sticks, and whiplashers; rick-cloths, winnowing-sheets, and carriage-wrappers; and a collection of three, four, and five-bushel sacks.

HARDING, Wincanton.—Harding's genuine horse food, in casks, canisters, and packets.

FENNEY AND CO., Lincoln.—Patent adjustable corn-screens and separators; sack-lifters; improved registered gravel, sand, coal, and malt screens; rolls of galvanized game and poultry-netting; and six galvanized wire meat safes.

HAWKES, SPENCER, AND CO., Tiverton.—Eight, nine, eleven, thirteen, and fifteen-row patent chain corn drills; three-row turnip, mangold, and manure drill; single and double-action turnip cutters; patent self-acting horse-rakes; hay machine; reaping machines; patent fire-bars; and washing machines.

CARSON AND CO., London.—Samples and patterns of the original anti-corrosion paint; samples of varnishes, raw and boiled linseed oils, turpentine, and paints; and an assortment of improved brushes and materials for painting purposes.

COLMAN AND MORTON, Chelmsford.—Variety of patent cultivators, with five and seven tines; improved one-horse gear; water or liquid-manure cart; patent adjustable rotary corn screen; new patent oilcake cutters for hand or steam power; and samples of shares, &c., for Colman's cultivators.

REEVES, R. AND J., Westbury.—Two, three, and four-row liquid manure and economical seed-drills; eleven-coulter small-occupation corn-drill; patent broadcast manure distributor; and improved portable barrow-pump.

PAGE AND CO., Bedford.—Improved draining pipe and tile machine; patent horse, hay, corn, and stubble rakes; one and two-horse wrought-iron ploughs; sets of diagonal iron harrows; improved one-row combined expanding and universal steerable horse-hoes; and improved linseed-cake mills.

CAMBRIDGE AND CO., Bristol.—Improved Cambridge roller and clod crushers; patent notched-wheel rollers and clod-crushers; sets of three and four-beam combined tine and chain harrows; three-wheel land-presser; one and two-horse gear; twenty-three and twenty-six teeth horse-rakes; and Gardner's single and double-action turnip cutters.

WOODS, COCKSEDEGE, AND WARNER, Stowmarket.—One, two, and four-horse power vertical steam-engines, complete; universal grinding and crushing mills, for oats, beans, barley, linseed, malt, wheat, peas, maize, &c.; Gardner's single and double-action patent turnip-cutters; improved root pulpers and graters; improved horse-works, with separate intermediate motion; portable corn-grinding mills, with twenty and thirty-six inch French burr stones; improved oilcake breakers, patent perfect hog-troughs, one-horse carts, to carry thirty ewts., and Woods' one and two-horse mowers and reapers.

WOOD, W. A. (CRANSTON), London.—One and two-horse Wood's Royal grass-mowing machines, with and without reaping attachment; Wood's Royal one-horse reaping machine; and Nova Scotia grindstone, for sharpening reaper and mower knives.

WILLIAMS AND CO., Falmouth.—Miniature waggonette to carry four persons, two and four-wheeled dog-carts, and harvest waggon.

CROGGON AND CO., London.—Variety of galvanized iron pails, turnip skips, bowls, and basins; rolls of asphalt, in-odorous, ship-sheathing, and dry hair non-conducting felts; models of sheds and galvanized iron church; samples of Kamptulicon floorcloth and stall planking; two garden engines; galvanized iron cistern, gas stoves; samples of perforated iron and zinc asphalt blocks, shovels, spades, and forks; and rolls of strand wire fencing.

ROLLINS, London.—A large assortment of patent American domestic, well, suction, and force pumps, of various power; patent American aquarius and hydraulic ram; bundles of American hay and manure forks; Nova Scotia grindstone and

India pond extra scythe stones; improved American wheel horse-rakes; variety of small American implements for farm and household use; set of American thermometer charts; and assortment of Shaler and Fairbank's weighing machines, weights, scoops, &c.

ASH, Penzance.—Two and four-wheel dog-carts and park phaetons.

BEARE, Newton Abbot.—Three and five-horse power portable thrashing machines; three and five-horse power portable gear; three-row turnip and mangold drill; winnowing machine, patent "Eclipse" reaping machine, combined reaper and mower; and Riche's and Waits' patent "Eureka" grist mills.

RICHMOND AND CHANDLER, Balford.—Assortment of chaff-cutters of various size and cut, to work with hand, horse, or steam power; corn crushers; one, two, and four-horse gear; root washers, turnip cutters, steaming apparatus, sackholders, and bread-kneading machines.

TIPPER, Birmingham.—Cattle medicines; Tipper's medicated mystery, for cows, calves, sheep, pigs, poultry, and dogs; and sheep-dipping apparatus for scab, tick, and fly.

INLEFF, Ladbroke, Cornwall.—Variety of cemetery memorial stones, pillars, and crosses.

MITCHELL AND BURGESS, Manchester.—Emery composition grinding machines and files for ordinary and reaper knife sharpening, and portable stand for holding reaper knife bar while being sharpened.

MOUL'S PATENT EARTH CLOSET CO., London.—Specimens of the patent earth commode, with pull-up and self-action, made of various woods; patent dustless earth and cinder sifter, patent earth urinal, sets of self-acting and pull-up apparatuses, drying stove for drying earth, and galvanized iron tanks for earth closets.

DAYE, Croft-hole, Cornwall.—Excellent turn-wrest ploughs, with steel breast, skid coulter, and parallel self-acting wheels; portable horse rake, and set of tubular whippetrees.

DAY, SON, AND HEWITT, London.—Stock-breeders' complete medicine chest, containing "Guide" and large assortment of cattle and sheep medicines and compounds; chests of chemical extracts, gaseous fluid, red drench or inflammation powders, red paste or condition balls, for the cure of the various complaints and diseases incidental to horses, cattle, sheep, &c.; the aluminates of zinc and sulphuretted extract ointments; and four pamphlets—"Key to Farriery" (two editions), "Prize Essay on the Rearing of Calves," and "The Breeding and Management of Sheep."

BAKER, Newbury.—Liquid manure or water cart, on 4-inch wood wheels; liquid manure distributor; pump, with 12 feet of suction hose attached; and 130-gallon liquid manure cart, with distributor attached.

SILVESTER, London.—Patent American scales, improved American blade sharpener, and patent noose ring for leading cattle.

HARDON, Manchester.—Samples of royal patent cake, and original condimental food for feeding and health restoring.

FETHICK, Plymouth.—Two-horse farm carts for general purposes.

TERRELL, Redruth.—Six sizes of improved cooking apparatus, fitted with every requisite for domestic use, and made of various measurement.

JONES, Gloucester.—Composition for waterproofing, softening, and preserving leather; and Gloucestershire specific for foot-rot in sheep.

PARHAM, Bath.—Assortment of iron, tubular, and ornamental field, garden, and wicket gates and pillars; rolls of continuous galvanized wire fencing for cattle, sheep, dogs, poultry, &c.; ornamental hurdles, with trellis and chain tops; strong wrought-iron cattle crib; various garden seats; and specimens of verandahs.

HEPBURN AND SONS, London.—Lengths of stout double and single leather belting, mill-band strapping, and driving bands of various weight, length, and width; lengths of leather pipe and suction hose; leather fire buckets, strap screws and fasteners, and hydraulic leathers; and canvas hose for fire engines and liquid manure carts, tanks, &c.

BEACH, Dudley.—Beach's farinaceous food for cattle, sheep, and pigs; condiment for horses; and superfine flour.

GLIDDON, Taunton.—Open fire kitchen range or cooking apparatus; steaming apparatus for domestic use; "People's" cooking range, and "Vesta" cottage range; suspension roast-

ing apparatus, fitted with tin screen; enamelled iron bath, complete; and (new) screw-down tap, for all kinds of spirituous and malt liquors.

**DODGE, London.**—Rolls of india-rubber and vulcanised machine-bands of various length, width, weight, and substance; vulcanised india-rubber hose and tubing for fire-engines, breweries, manufactories, &c.; assortment of useful india-rubber articles for domestic and other purposes; india-rubber waterproof covers and sheeting; ditching and malting-boots, driving-aprons, capes, coats, &c., and gutta-percha driving-bands.

**COOK, Redruth.**—Two-wheeled Malvern dog-cart, and four-wheeled phaeton.

**THE BOVEY TRACEY POTTERY COMPANY, Bovey Tracey.**—Fire and architectural brick goods in great variety, for all purposes.

**BULLEY, Plymouth.**—Miniature brougham, Victoria barouche phaeton, and skeleton-body park phaeton.

**MAJOR, Bridgwater.**—Model roof, exhibiting various kinds of roofing and other tiles.

**BROWNE AND CO., Bridgwater.**—Variety of plain and moulded bricks, tiles, and pottery.

**SKETCHLEY, Weymouth.**—Six-horse power portable engine, universal joiner, batting sawing machine, and mortising machine.

### THE ANNUAL MEETING

Of the members was held in the council tent at 12 o'clock on the Wednesday, Sir John Duckworth, Bart., the President, in the chair.

The SECRETARY (Mr. Goodwin) read the following Report: "The Council have the gratification to announce that, notwithstanding the decease of several valuable members, prominently among whom must be mentioned the late John Sillifant, Esq., of Coombe, in the county of Devon, there has been no serious diminution in the number of subscribers. There are at present on the books 69 life governors of the Society, 101 governors, 554 members subscribing not less than £1 annually, and 253 members contributing 10s. annually; total, 977. The growing disposition of local agricultural societies to enlarge the area of their operations, and to invite the manufacturers of agricultural implements to exhibit at their shows, has entailed on that enterprising body of men a great increase of cost and trouble to meet the requisitions of the various annual exhibitions. When therefore a proposal was lately made by the Southern Counties Association, embracing the counties of Hants, Berks, Oxford, Sussex, Surrey, and Kent, that their association should be amalgamated with this Society, the Council was induced in great measure by this consideration to appoint a special committee to confer with a corresponding body of the Council of the Southern Counties Association; and, after mature consideration, it was in the first instance resolved at a special meeting of the Council, held at Taunton, on the 14th of March, and afterwards confirmed at an ordinary meeting, held on the 28th of March, that it is desirable for the amalgamation proposed by the Southern Counties Association to be acceded to on the following terms: 1. That the name of the amalgamated society be 'The Bath and West of England Society (established 1777) and Southern Counties Association.' 2. That the rules of the Bath and West of England Society be adopted as the rules of the amalgamated society. 3. That in the united Council the vice-presidents and half of the Council (18) of the Southern Counties Association be added to those of the Bath and West of England. 4. That the office do continue at Bath, and the officers of the Bath and West of England Society become those of the amalgamated society. 5. That the meetings of the Council be held at Yeovil. To this proposal the Council recommend that the annual meeting give effect. The Council are happy to announce that the financial position of the society is satisfactory. The funded capital has not been in any way diminished during the last three years, and it is hoped that the experiment of holding a meeting so far west as Falmouth will prove conducive to the great objects for which the society was founded. The exhibition, though not so large as on several previous occasions, has the merit of great excellence. Stock and poultry are represented by fine specimens of the best breeds, machinery and implements by the productions

of many of the best makers from remote parts of the United Kingdom. The Art Department is replete with works of great merit by living artists, whose names are annually becoming more familiar to the frequenters of the society's exhibitions, and the Council desire to record their obligations to the Lord President of the Privy Council, and the authorities of South Kensington Museum, for the fine collection of objects in decorative art entrusted to the society for exhibition. An invitation having been received from the Mayor and Local Committee of the town and county of Southampton to hold a meeting there in 1869, the Council recommend that, subject to the usual requirements of the society being complied with, the invitation be accepted. At the last annual meeting a proposition was made that a petition should be presented to the Legislature in favour of stricter regulations in reference to the importation of cattle from foreign ports. The subject was referred to a special meeting of the Council of the Society, and a memorial, which it is hoped has not proved fruitless, was presented to the Privy Council. The Council recommend that the Earl of Carnarvon be appointed to the office of president for the year 1869. To supply the vacancy occurring in the Council by resignations and the usual retirements, the Council recommend that the following members be elected: Mr. Wm. H. P. Carew, Antony House, Torpoint, as vice-president. (The names of the Council included the Rev. A. Thynne, Penstow, Stratton, and Mr. E. B. Williams, Nanskeval, St. Columb.)

On the motion of Mr. JONATHAN GRAY, seconded by Mr. P. P. SMITH, the report was received, adopted, and ordered to be circulated among the members of the society.

Mr. POOLE, in pursuance of notice, moved an alteration of the sixteenth law so as to allow of a general law being altered at a special general meeting as well as at annual meetings. The motion was seconded by Mr. HUSSEY.

Mr. WILLS thought the alteration unnecessary, as the members of the society put the greatest confidence in the Council, by whom the whole of the business between the annual meetings might be transacted as heretofore.

Mr. ACLAND, M.P., pointed out that it would be impossible to complete this amalgamation with the Southern Counties Association without altering some of the laws, and it would be a pity to leave the matter in an unsettled state for twelve months till the annual meeting.

No amendment was proposed by Mr. Wills, and the motion was then put and carried.

The Rev. T. PHILLPOTTS moved that the proposed amalgamation with the Southern Counties Association be approved and confirmed.

Mr. SPOONER, of Southampton, seconded the motion, which was carried.

Mr. POOLE moved the appointment of a committee to consider and report to a special general meeting of the Bath and West of England Society, how the proposed amalgamation could be best carried out, and what alterations in the rules were required.

The motion was seconded and adopted.

Colonel ARCHER moved that the Earl of Carnarvon be elected the president of the society for the ensuing year, which was seconded by the Rev. T. PHILLPOTTS, and carried unanimously.

Mr. FARTHING then proposed, and Mr. STOKES seconded the election of the members of the Council as recommended, which was agreed to.

On the motion of Col. Archer, Mr. W. H. Pole Carew was elected vice-president of the society.

A vote of thanks was then accorded to the chairman for the ability and courtesy with which he had presided over the proceedings of the society; and at a meeting of the council immediately preceding the annual meeting, it was resolved that the best thanks of the Council be presented to the chairman, vice-chairman, and the members of the local committee, for the liberality with which they had received and entertained the society, and for the zeal and ability with which they had laboured to bring the meeting to a successful issue.

## THE ISLINGTON HORSE SHOW.

There is a story told of a man who, on his return from the Derby, was found hurrying over his dinner in the coffee-room, and who, on being asked the reason for all this haste, answered that he was going to Astley's, and was afraid he might be late! It would have been imagined that he had seen quite enough of horses for once in the way, although we still finish the week much as this enthusiast did his day out. Astley's Amphitheatre is, to be sure, shut up and to be sold; but after the week at Epsom we wind up with the horse show at Islington, and it comes to much the same thing. There is the same smack of the sawdust, the like scenes in the circle, the lofty jumping, and "Pay here for the boxes." If they would only run a tame far now and then round the ring the illusion would be complete.

With some considerable experience of such meetings we have long thought that the horse show might be made something more of. There can be no disguising the fact that on the turf the horse is regarded merely as an instrument of gaming, and that the countenance of the Government in the way of Royal Plates, to be run for at comparatively heavy weights and long distances, has come in its influence to be little more than a nullity. Surely some of the thousands of pounds annually wasted in this way might be advantageously applied in some other direction. At any rate, the experiment is worth trying, for nothing could promise to be more idle or useless than this expenditure, as at present persisted in. Let there be a few of the Royal Plates devoted to the encouragement of sires either for the saddle or harness, and a few more of her Majesty's gifts be offered for hunting-horses of certain ages and capabilities. A very small modicum of patronage of this kind would have a very great effect. It would give a stamp to the thing, and incite many more people to exhibit and improve, who may not as yet have thought much of these opportunities. The Royal Agricultural Society of Ireland is indeed about to take the matter up, and address the Government on the deterioration in the breeds of horses. Unfortunately the Charter will not permit of the Royal English Society going before Parliament, or the Council might do something of the same kind, say in the course of the next ten or twelve years. Of course a vast deal will depend upon the conduct of the shows. If such a gathering be regarded chiefly as a scheme for getting shillings and halfcrowns out of the public, our argument would be as false as if we went for breeding horses with main consideration of the hundreds and thousands the black-legs may get out of the public. If with this one great object in view an irrepressible air of absurdity is to characterise the proceedings; if the unfortunate horses are to be "jumped" and "jumped" again from one week's end to the other, and as an attractive finish to run trotting matches in a circus, we merge the horse-show into the fair show. There was during the Monday in Whitsun week an entertainment at Islington, in the course of which "lady jockeys" rode a steeple chase "over four water jumps and eight fences," with a display of fireworks in the evening. It is only right to say, that this exhibition was not be in the Agricultural Hall, but on the adjoining County Cricket Ground. There was, however, it is fair to add, "extra prizes for trotting and leaping" in the Agricultural Hall, and sportsmen and horsemen could have had the opportunity for comparing these grand national demonstrations one with the other. There was, though, no

fireworks after the trotting, an almost culpable omission, which the directors should order their people to see to by another year.

To our thinking, the sportsman should have no greater treat than a well-conducted horse-show. Let us take him on a month or two, when in the centre of a great grass ground three gentlemen have some of the picked nags of all Yorkshire parading around them. Beyond a solitary attendant at the gateway there is not a soul to interfere with these authorities. The very horse seems to make his entrance and exit by instinct, and though possibly once or twice during the day a varmint-looking gentleman with a certain official air about him may cross the scene, it is as likely as not that he never exchanges a word with the judges, but, in the exercise of excellent taste, leaves them to their duties, content to see that the genius of good order still reigns supreme. There are no trotting matches, there are no "leaping" matches; but if a man wishes to try a horse, there is a row of bushy hurdles in a quiet corner, at which he may put anything he has in price. But what does any true sportsman think of this jumping in public? Mr. Thomson's clever horse would not have it at Islington, and another that took a first prize as a hunter absolutely refused to have anything to do with such Cockney contrivances. As *The Times* has it, "One horse walked up against the fence and coolly pushed it down, and another showed his intelligence by selecting a break between the tressels, through which he shambled much as a donkey would manage a two-foot ditch. It is a pity better arrangements were not made for jumping; although no judge would think of condemning a hunter for refusing a fence with a crowd close under his nose, laughing, shouting, and cheering by turns." And yet horses were sent time after time over "the jumps;" while Lord Macclesfield stood by, with a smile of something like shame on his face, and the officials and the other "set" and the directors, and the visitors, and the clerks of the Company, and the distinguished foreigners got in each other's way, and took complacently enough to judging the judges. What a fuss they did make of it, to be sure! Every now and then somebody sounded an alarm, a cross between a gong and a dinner-bell, and one was irresistibly reminded of the "Walk up! walk up! all in; just a-going to begin!" Then a director said to some unfortunate groom in charge of a horse, "Now walk!" and then somebody else, who wasn't a director, squeaked out, "Now trot!" while a third ordered him bodily out of the ring, and a fourth told him to stop where he was! And then they all went and bowed and smiled at the judges, under the manifest impression that they had been doing a deal to facilitate the business! But how is it there are no gongs, no board of directors, no distinguished foreigners, no clerks, to interfere with the arrangements of a Yorkshire meeting?

The Horse Show pays; but we should like to see the horse show regarded as something more than a successful speculation. Everybody, as it is, seems to treat the thing as a joke. People laugh, as they would at "Mr. Merryman," when a beaten horse runs round and nearly over an official. The proceedings, moreover, occasionally approach very closely upon acts of cruelty, and many a horse may never forget the "bucketing" he gets here. With some love, and we had almost added respect, for a horse, we have been induced to say so much upon so much that is objectionable in this now annual exhibition.

The doors opened for a fifth Show, as usual on the Saturday after the Derby, and in the course of the day there were a fair number of visitors. There were two sets of judges—the lords and commons: the lords commencing the business of the day a little after ten, with the weight-carrying hunters, a rather heavy class, numbering fifty. Amongst these were about a score that looked like hunters, and two notorious impostors who have taken their value in prize-money a hundred times over, as neither of them as hunters is really worth a ten-pound note; and we hope, for the good of the cause, of horse-shows in particular, that they will never have another penny awarded them. Those that struck us as possessing hunting characteristics were Mr. Anstruther Thomson's Borderer and Valeria, about which there could be no mistake, although we think there decidedly was, in giving Miss Tyler's Tyroconnel a place, for he has anything but a hunting forehead. Capt. Percy Williams, who has often acted as judge in the Hall, had a big slashing five-year-old with rather a loaded shoulder and strong round flashy action, that would require a deal of steam to keep him going, and who smacked a little more of charging than staying with hounds; but he is a young one and big one, so time may work wonders as he sobers down. Mountain Dew, a well-known prize-taker, and a hunter all over, being a capital goer and a fencer in the open, would not have anything to do with the jumping business here, many more horses following suit during the day, including Capt. Thomson's good-looking hunter, Borderer. Can this be wondered at? As well might we expect hunters to take to sawdust and face gaudy green-pea-coloured leaping-bars topped by rows of Lincoln and Bennett's, or Christy's best, and the staring heads within them, as a good man across country, to don a chignon, long stockings, and short gauze petticoat, and be as *au fait* in simpers, curtsies, and turning heels over head, or jumping through a hoop, as the American Ella himself. Mountain Dew has thickened, but would have shown to more advantage with less carcass. Mr. All-sopp's Sparkenhoe was a really gentlemanly-looking horse, of fine form, breed, and action, his legs coming well under him; couple with him Mr. Davies Bryan's Hereford, and you have two horses very taking to the eye, and of excellent symmetry. Captain Heath's Chicken caused much merriment from his description in the catalogue as standing "16 hands 5 inches high, a wonderful hunter up to 17 stone." Five inches! while the dam of one of the stud horses was stated to be a well-known stallion! Mr. Manner's Phalanx was a compact good-looking horse, but with something more of the charger in form and action; as was Colonel Carleton's Warkworth, but we doubt not that both can take their turns as hunters. Mr. Fison's had breed, and could move. Mr. G. Stones' Middleton, and Mr. S. Copestake's Bellerophon, and Mr. Booth's Shamrock, were good-looking, the latter lighter in his carcass than his owner is in the habit of showing horses. Lady, an old-fashioned hunting mare of Mr. Codrington's, looked more like sixteen than six; and Lord Ingestre showed four, Godfrey and Gurney being our fancy, the latter a useful, good-topped horse on a short leg with fair action, but not over fast looking. Colonel Somerset's Tom Steele is a quick-looking grey, with bone, and Mr. Greetham's a fair-looking chesnut. Voyageur has a shoulder that would stop one of Stephenson's locomotives, and Master of Arts, though grand in his top, is the most wooden choppy goer that ever put his head through a breast-plate: both were in excellent trim for the German sausage market, a market that by nature they are much more adapted for than Market Harborough, or any other hunting country, though kept in the ring till the last. The

next class, forty-eight in number, for hunters without condition as to weight, was headed by a lengthy, well-formed, gentlemanly horse of the Prince of Wales', Knight of St. Patrick, who was awarded second honours, a horse that the owners of a great many in this class might try and carry away in their eye, just to give them some notion of what a hunter ought to be—a thing, judging them by some of the brutes exhibited, they must have but a very few loose ideas about. In fact, there was a deal of weeding, which might have been done with a very wide hoe in a very little time, without the slightest chance of injuring a good plant. Denmark, a very useful but rather plain horse, the judges did not take to, and although with many of the characteristics of his brother Mountain Dew he has more of the charger about him, and he made his exit, never to return, with such horses as Mr. Paull's Plaudit, Mr. Drage's Thorpe Malsor, Mr. Sander's Crik, Col. Somerset's two, Aërolite and Carnarvon, Mr. Pagden's Confidence, Mr. Greetham's chesnut, whilst horses with shoulders like Mr. Clarke's Rosa, Mr. Raikes's Amazon, and Mr. Davis's Chevening came labouring in a second time and were kept before their lordships till the last turn. The Honourable Mrs. Villiers, a fine woman across country in her day, sent a very neat, compact chesnut, Toby, but who wants his shoulders shaved to make him perfect. Among those good-looking were Mr. Kirk's Bayard a good-topped, useful horse; Mr. Bevan's black mare, by Sir Hercules, with form, breed, and action; Mr. Newman's Prince; Mr. Lloyd's Planet; Mr. Topham's Springy Jack, third here last year to Brayfield and Goldfinder; and Mr. Thomas Bradfield's Harkaway. With something about them commendable were Mr. Mitchell's Orion and Esquire, and Mr. Barker's Tom Bowline; but the beauty of the hour, and who received her honours amidst a general clapping of hands, was Lady Derwent—a lady not only by title, but in manners, form, and carriage—who for symmetrical proportions, strength, and breed is a Venus in horseflesh, and if it were not for a deep dish in her frontispiece, some three inches below the eye, which nearly approaches to a deformity, she would be perfect: she was the best and Cup four-year-old at Driffild last year. The third was the well-known General, whose carcass was a little too big; he has thickened considerably, and is deservedly a great favourite with most people; if he has a fault, he is rather long from the elbow and stifle to the ground, or short from whirl-bone to stifle. For hunters without condition as to weight, and not exceeding fifteen-two, there were nine fair ones out of the twenty-three. Chillon, a black, well-built gelding, was considered the best by their lordships. Nutbourne running him very hard, as he was a really nice one. Sir George Wombwell sent a very nice bloodlike chesnut mare, a little slack in her back; and Mr. Cox has a capital framed one in Star; whilst Mr. Addison's Idle Boy, Mr. Barker's Exchange, Mr. Beck's Peter, Mr. Newman's Fire King, and Mr. Hall's Nimrod were commendable for looks. Out of the thirteen four-year-olds there were five somewhat in the form and fashion of hunters, the prize going to Nugentstown, a useful, hardy-looking chesnut belonging to a noble lord whose name ought to be familiar to most foxhunters, or at least to those who do not labour under the same infirmity (if we can call it one) as a well-got-up swell in a train the other day, who declined our proffered *Telegraph* in the most off-hand manner with "I kent read." The second, Brigadier, a powerful, deep-topped horse, with a sensible head if not a handsome one, would have shown to more advantage if he had not been suffering from the Killerby Hall complaint—too much to eat. Mr. Goodliff's Father Mourad, said to be by Trumpeter, appeared to be very good-looking; whilst Mr. Topham's brown by the Ugly Buck was a taking horse spoilt by a slack

loin, and Mr. Toynbee's Bird's Eye was neat, quick, and a goer. Then came feeding time, and the Lords to luncheon, and the Commons proceeding with the park hacks and ladies' horses, horses of all shapes and sizes with jockeys to match, including the guardsman in uniform, who lives on his pay, proud of his weight and inches, down to the bow-legged stablelad, who, if he could only have kept that deformed bit of humanity within eight stone seven, might have had a valet, dined with dukes and marquises, and been lauded by toadying scribes as the great jockey So-and-so. The first and second were neat hacks of fashion, and the third a light, leggy charger; but Cuirassier pleased us far more as a charger. General Hess, by The Nabob out of Lady Alice by Lanercost, was first in the thoroughbred stallions in a class of nine. He is a nice-looking horse, with good ends and fair middle; the second being Idler, by the Flying Dutchman out of Urania by Idle Boy, a varmint, hardy-looking horse with fair ends and limbs, but a hollow back, and we fancied rather light in his thighs. Mr. Stiggins' still looks like a good useful horse for the country, so far as shapegoes. John Halifax is a big one; Ivanhoff the handsomest and best-halped of the lot, cut him off at the knees; Brown Dayrell coaching-looking; First Hope a weed; and Mail Train so overloaded with flesh that he seems short and over-topped, and looks nothing like so well as he did a month or two ago, when we saw him knocked down at Tattersall's at something over ten guineas, which we thought at the time remarkably cheap. The roadster stallions were not a grand class, the prizes going to three roans—Rapid Roan, a rather good-looking roadster with a heavy forehead and waspy middle, but a first-rate goer, was shown at the meeting of the Royal last year at Bury, when he only came in for a commendation. Young Performer is anything but a true-made one, with not the best of heads; while Young Phenomenon, though he can go, almost comes under the denomination of a two-ended horse, having but little middle. The prize stallions under fifteen hands were not a strong lot—the first a three-year-old, Merry-legs, being a very true-made hack with good ends and no lumber; and the second a good goer of fair form. So far, we have seen better horses in all these classes at the Agricultural Hall.

Of cover hacks and roadsters, from the glimpse we got of them in their stalls, there appeared to be some fair samples; but of course action would go a great way. Cheltenham Tommy, a strong short-legged cobby hack, is more remarkable for useful than elegant looks, while the Dorking lass, Brown Duchess, shows a deal of quality with a handsome top and capital shoulders, but not the best formed forelegs. Cheshire Phenomenon is one of the roan Norfolk trotting tribe, some of which are strong useful hacks enough, but too many like our Cheshire friend, whose shoulders always remind us of Sinbad the Sailor and his hanger-on the Old Man of the Sea. It is quite astonishing the number of really good-looking horses one comes across, who if not burdened with this incubus would be all but perfect. Romulus and Remus found room in the Agricultural Hall, the former a very good-looking lengthy grey cob, carrying off the first prize for park hacks up to weight; the second to him being Hero, another handsome one of his sort, but a very different stamp, being a powerful cob, something of the Cleveland cart-horse in miniature. He was steered by a feather from Pimlico, man and horse appearing to be cut out for one another. Mr. Salter's Young England was a powerful cob of somewhat the same class, and a very useful animal for a welter weight. In the harness class Romulus was again elected, beating Nellie, coming from the same Common, a very neat little hackney mare, perfect in manners in a gig, with nice quiet elegant action, and who, it will be seen,

heads the list in another class of park hacks for riding purposes. Highflyer came in for a commendation, a cobby hack that could step; and there were some others worthy of mention, but nothing extraordinary. The Prince of Wales had a couple in the next class of park hacks. Lord Macclesfield acted for Col. Kingscote, the Master of the Horse to the Prince, who retired from the ring for the time. Rupee is a fair hack; Le Vent, a bay lathy Arab, perfect in his manners as a lady's horse, and quietly ridden by an unassuming horsewoman; while the third prize, Bridesmaid, is a nice hack, with some style, but a trifle thick at her shoulder points. We don't hold with applauding or hissing gentlemen while acting as judges, as you would a lot of mountebanks; and knowing how easily an audience is led on to hiss or cheer, we look upon such ebullitions of feeling with some doubt, more especially when there are more blanks than prizes; but the mistake here is clearly the plan of conducting the whole thing, more like a second-rate circus than a meeting for sportsmen and horsemen. Moreover, this is the only show of the kind, that we know of, at which the judges are supplied with the names of the exhibitors. At all other meetings the awards are made by numbers, and it was in this way that the late Prince Consort gained his many premiums at the Royal Agricultural Society and Smithfield Club. But at the Islington Horse Show, with stewards and others continually earwigging them, it was concluded that the judges knew the Prince's entries; and hence the sad scene that occurred. Any man may make a mistake, a peer perhaps as readily as a commoner; but the question is why a lord should be made an exception, and put in a position manifestly to his own disadvantage? If the ring were kept thoroughly clear, if the lords were left to themselves and their books, which should give nothing beyond the conditions and the numbers, their awards, let them be ever so indifferent, would hardly be received with *hooting and hissing*. We have seen as many horse shows as most people; but we remember no such demonstration as this. Katplan, one of the Arabians presented by the Sultan to the Prince, was here, and looks much improved since he has been in this country. Miss Letitia Millard, quite a feather in a skirt, handled a chesnut with a big knee in an artistic manner, but so quietly, that it was a treat to see, after the exhibitions one had to endure year after year of a rough-riding amazon, with no hands, who was always pulling and hauling away at her mount, or on the grin with mock-modest smiles and leers. After Lord Macclesfield left, there was fearful pottering and waste of time with the Commoners, who seemed to have no method whatever, and when they came to the park hacks under fourteen hands and a-half, their feeble hesitation was almost unbearable. The Hero, who with his rider went round and round the ring time after time till he sweated again, must have found this out. Mr. Salter pulls down with his saddle a trifle more than eight-stone-ten! Round and round, again and again, and then they are pulled up for inspection, and the more the judges look the more they hesitate, and the more undecided they get. Then the gong is struck by some one, time after time, for the next class, muffins, more champagne, or perhaps in the hope of hurrying on the trio to a decision; but it has not the least effect, and there are offers of 6 to 4 that the judges, like juries, will have to be locked up. Statue-like they stood; then a yoice-over noisy gentleman tendered his advice, pointing first to one horse and then another. At last they decided by disappointing all those that did not get prizes, more especially Hero and his rider, who had not had such a bucketing for many a long day. Nellie, as we have said before, was first, though we liked her better in harness; Fenette is a small chestnut mare, not much to look at, with good fast flourishing but

vulgar action, and Quiktailver a cobby hack. There were several in the class, for there were all sorts, weight-carrying cobs, etcetera, that, before another bunch, like spirit-rappers, might turn the tables. Black Jessie, standing fourteen hands, was really a charmer in harness, with neat useful action; while Miss Menken was a common looking cob hack, not remarkable for head, shoulders, middle-quarters or limbs, and no compliment to the "adorable Mazeppa," as the Frenchmen christened her. Puss, a dun, with a hog mane, and a very short round bushy tail that looked like a chignon, so artificially was the little kitten got up, did not want for action or knowing looks. In the ponies not exceeding thirteen hands, Maltum in Parvo is a really nice pony, very showy, with form, breed, and stylish action; and Jacob, a black, neat, clever goer, without any nonsense; while Black Prince is quite a different stamp to Maltum in Parvo, with short hammering action. There were one or two nice harness pairs, the cream of the lot, or rather their owner, coming from Argyleshire. The customary tom-foolery in trotting came off on Friday, for a higher title you cannot give it; a groom with a varmint-cover hack in a high mail-cart, went over a crasher at one of the turns, and while they got the horse free and gathered up the pieces, there was a pretty general verdict of "served him right." Later in the day another servant was taken off senseless, and it was thought at first that he had been killed outright. Shepherd T. Knapp, the American, was in full force: he has rather a heavy neck and head, but a round deep middle piece, great quarters and limbs, and is a really fine fine-goer. The wind-up was with the jumping, a good-looking horse of Captain Carleton's, with something of a charger-like forehead, taking the artificial double in and out, and topping a rasper in hunter-like style. The second-best was Buzzard, a light, blood-like, steeple-chasing looking animal of good form. Lord Combermere, Captain J. Anstruther Thomson, and Captain Percy Williams were judges of jumping, and superintended the arrangement of the fences. Two or three came to grief—one a trooper, who stood much more chance of being down among the dead men, or maimed by an ugly roll he got underneath his horse, than he would, by all accounts, if in the Abyssinian rook-shooting party. Another, a dealer-looking man in a white hat, took the fences very decently several times, but at last put a climax to his crimes by getting an awful purl, plunging the tan with his nose, and turning up with his face dyed. He retired for a while, and then was ushered in again, looking very ruffled; but, on Captain Percy Williams presenting him with a bit of yellow ribbon, which appeared to set him back of Gilead, he gained his proper equilibrium; for no sooner were the colours fastened to the horse's head than the battered white hat was seen topping the bars, amidst continual applause, and Solomon was once more in all his glory!

## PRIZE LIST.

### HUNTERS.

JUDGES.—Lord Combermere, Lord Macleanfield, and Lord Kesteven (and for Thoroughbred Stallions).

Weight-carriers up to 15 stone: First prize of £80 to Capt. E. N. Haygate, Buckland, Leominster (Mountain Dew); second of £40, Miss Tyler, Wareham (Tyronnel); third of £20, Mr. J. Anstruther Thomson, Drizworth (Borderer).

Without condition as to weight: First prize of £50 to Mr. E. Horaby, Ganton, Yorkshire (Lady Derwent); second of £25, E.R.H. the Prince of Wales (Knight of St. Patrick); third of £15, Mr. T. Gee, Wadhurst, Sussex (The General).

Without condition as to weight, and not exceeding 15 hands 2 inches high: First prize of £40 to Mr. J. Casson, Bough-by-Sands, Carlisle (Chillon); second of £20, Mr. W. J. Lloyd, Watford (Nestbourne).

Four-year-olds: First prize of £50 to Lord Somerville, 35, St. James-street (Nugentstown); second of £25, Mr. J. B. Booth, Killerby, Catterick (Brigadier).

### STALLIONS.

Thoroughbred: First prize of £40 to Lord Spencer, Althorpe Park (General Hess); second of £20, Mr. T. Merrick, Northampton (Idler).

Roadsters not less than 15 hands high: First prize of £25 to Mr. E. Jolley, Banham, Norfolk (Rapid Roan); second of £15, Mr. J. Rowell, Bury, Huntingdon (Young Performer); third of £5, Mr. J. Abel, Norwich (Young Phenomenon).

Stallions under 15 hands, for getting Hacks, Cobs, or Ponies: First prize of £15, Mr. W. Major, Malton (Merry-legs); second of £10, Mr. D. Lister Westwood, Ilkey, Leeds, (Black Performer).

### HACKS.

JUDGES.—Colonel the Hon. Charles Hay, Colonel Kingscote, and Mr. Harvie M. Farquhar.

Park Hacks and Ladies' Horses of any height: First prize of £20 to Mr. J. G. Morrel, Notting Hill (Jenny); second of £10, Sir E. C. Dering, Pall Mall (Quicksilver); third of £5, Lieutenant-Colonel Dougall Astley, 40, Belgrave Mansions (Napier).

Cover Hacks and Roadsters, not exceeding 15 hands 2 inches high: First prize of £15 to Mr. T. W. Potter, Earl Court, Cheltenham (Tommy); second of £10, Mr. W. Morley, Eppingham Hill Lodge, Dorking (Brown Duchess); third of £5, Captain St. Clair Ford, Zeelugt House, Cheltenham (Cheshire Phenomenon).

PARK HACKS, WEIGHT-CARRIERS, not exceeding 15 hands 2 inches high.—First prize of £20, to Mr. C. M. Baker, Clapham Common (Romulus); second of £10, to Capt. T. Hargreaves, Arborfield, Reading (Hero); third of £5, to Mr. G. H. Smith, Stamford Hill (Kitty).

HARNESS HORSES, not exceeding 15 hands 2 inches high, of the best shape, with park-action, in single harness.—First prize of £15, to Mr. C. M. Baker, Clapham Common (Romulus); 2nd of £10, to Mr. W. G. Clift, (Nellie); Highly commended and Medal, to Mr. W. Green, Leeds (Highflyer).

PARK HACKS AND LADIES' HORSES, not exceeding 15 hands 1 inch high.—First prize of £20, to H.R.H. the Prince of Wales (Rupece); second of £10, to Mr. Bedford (Le Vent); third of £5, to Mr. A. T. Hewitt, 38, Gloucester Place, Hyde Park (Bridesmaid); Highly commended, Mr. W. J. Beadale, Chelmsford (Duplicate). Horses, not exceeding 14 hands and a-half.—First prize of £20, to Mr. W. G. Clift (Nellie); second of £10, to Mr. E. T. Fowler, Jun., Gillingham Street (Finette); third of £5, to Mr. C. M. Baker, (Quicksilver); Highly commended, Mr. C. Groucock, Stanfield Hall, Wymondham (Pretty Season); Capt. Hargreave (Hero); and Mr. J. Casson, Carlisle (The Bean).

PONIES, not exceeding 14 hands, in single harness.—First prize of £15, to Mr. H. Beck, Brandon, Norfolk (Jessie); second of £10, to Mr. C. Dollard, Norwich (Miss Menken); third of £5, to Mr. C. Groucock, Wymondham (Puss); Highly commended, Mr. J. S. Calthorp, Isle of Ely (The Dandy); and Mr. W. M. Spence, Weston, Yorkshire (Venus); Commended, Mr. C. L. Sutherland, Croydon (Gipsie). Ponies, not exceeding 13 hands high, in single harness.—First prize of £12, to Mr. J. Gilman, Jun., Birmingham (Maltum in Parvo); second of £8, to Mr. H. Bullard, Norwich (Jacob); third of £5, to Mr. J. Hatton, Clapham (Black Prince).

EXTRA PRIZE: HARNESS PAIRS, not exceeding 14 hands.—First prize of £10, to Mr. C. M. Moreton, Lurgie Castle, Argyleshire.

GOLD MEDAL, as best of all the hunters, to Mr. E. Horaby (Lady Derwent).

## THE "EXHIBITION" AT ISLINGTON.

It is more than questionable whether the amusement which called forth so many bursts of laughter was of the right sort. If, instead of a trial of prize-hunters at fencing, this had been a donkey-race, or some clownish competition in which rough humour is an essential ingredient, the shouts of mirth would not have seemed inappropriate or uncomplimentary. As it was, the riding and deriding which went so closely together

were hardly well-matched. The horsemen who lost their stirrups, their temper, and now and then their seats, were bold equestrians certainly, or they would not have ventured on a public display of such remarkable incompetence. Some of them, with a grave persistency that was ludicrous to see, but is painful to think of, rode again and again at hurdles which there was not the least likelihood of their ever getting over, and seemed to be rather stimulated than discouraged by the re-echoing peals of laughter in their repetition of a wild rush, ending always in a sudden stop on the near side of the fence. Others belaboured their horses with heavy hunting crops over the head, on the cheek, anywhere, like mad tailors out for a holiday.—*The Daily Telegraph*.

The management depends chiefly upon the parades in the arena and the jumping burlesque as the chief "draws" for the amusement of the Londoners. No practical horseman would consider that hurdle-jumping in a public arena, when surrounded by a noisy crowd, ought to be regarded as any test of what a clever hunter could do in the open country, with the cry of the pack to stimulate his energies, and plenty of space to get into his stride, and to collect himself properly before taking off at his fences. Here I may state that this jumping buffoonery is a species of refined cruelty in which the female part of the assembly appear to take the greatest delight. Hunters that are positively as fat as prize oxen, from a cessation of work in the field, and that have been made up in flesh to hide faults, and show a sleek coat, are in a few instances galloped through the heavy tan flooring until the sweat rolls off them in streams, and then put at the hurdles when in a state of exhaustion, to blunder over them and come down "all of a heap" on the landing side. "Groggy" park hacks and stale old roadsters are also "rammed" at the hurdles by excited grooms and ambitious "swells," who appear to have had a few lessons in riding-schools, and take this opportunity to show off their seats.—*The Sportsman*.

Alas! the everlasting hurdles were introduced, and one of those bear-garden scenes, such a disgrace to the Islington shows, commenced; and in the first ten minutes there was as many spills as would occur in a quiet burst from Ashby or

Crick gorse. How fatal accidents were avoided is marvellous, and must be put down to sheer good luck, as horsemanship had nothing to do with it. What nerves people must have to charge different ways at the same place simultaneously! Of course collisions occurred, though none serious enough to cause damage. One man rode under the triangular props for the bell, instead of over the fence, and upset the lot, luckily clear of himself and every one else. Horses were galloped and jumped until the sweat streamed from them, the management considerably putting up four obstacles, instead of only two, as formerly; and, in fact, so abused and degraded were good animals by this farce that we took our departure in sheer disgust. Before closing these remarks, we must also refer to the catalogue, which was compiled with the usual care (?), and rivalled a pantomime in changing sex and colour; but the climax was reached in describing Captain Heath's The Chicken as sixteen hands five inches high!—*The Sporting Gazette*.

There may be a little of the circus about the show, and it goes on a day or so too long, but owners need not jump their horses unless they like; and with Dick Webster to lead the revels, and "tootle" the jumpers along, the Whitsun-tide visitors had a merry time of it. *This is, after all, the great consideration!*—*The Sporting Life*.

The jumping over the artificial fences caused great amusement to the visitors. As a rule, this is the most that can be said of this performance in so confined a space, for the display is utterly unserviceable for any assistance it affords to the judgment or estimate to be formed of fencing-power in the open.—*The Gardeners' Chronicle*.

The jumping business, to which strong objections are made by many of the exhibitors, serves to fill the Hall, and is unattended with danger.—*The Field*. [A groom who was thrown at a fence on Friday, according to the *Times*, "lay senseless and bleeding for nearly five minutes; but after a most painful suspense, he revived sufficiently to justify his removal, and later in the evening he was sufficiently well to walk. Altogether, the day was characterised by a series of singularly-narrow escapes."]

## HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

The monthly meeting of the directors of this Society was held on Wednesday, June 3rd, in Edinburgh; Mr. Stirling, of Kippendavie, in the chair.

The Secretary reported that, in terms of the instructions received at the special general meeting on the 13th of May, he had forwarded the addresses to the Queen and his Royal Highness the Duke of Edinburgh to the Duke of Montrose for presentation, and that his Grace has since received the following letter from the Principal Secretary of State for the Home Department: "Whitehall, May 27, 1868. My Lord Duke,—I have had the honour to lay before the Queen the loyal and dutiful address of the Highland and Agricultural Society of Scotland in reference to the atrocious attempt upon the life of his Royal Highness the Duke of Edinburgh; and I beg to inform your Grace that her Majesty was pleased to receive the address very graciously.—I have the honour to be, &c., (Signed) GATHORNE HARDY.—His Grace the Duke of Montrose."

A letter was read from the Board of Trade announcing that the Lords of the Council have refused to recommend to her Majesty to grant a veterinary charter for Scotland.

A plan of the yard at Aberdeen, showing the position of the different erections, was submitted and approved of.

Mr. F. N. MENZIES reported correspondence between the secretaries of the different railways in Scotland and himself in reference to some more liberal arrangement as to the rates charged for stock sent to the general shows of the society, from which it appeared that the subject was brought before a meeting of the general managers of the English and Scotch railways, held at the Clearing House in London, in May last, when it was decided to adhere to the following regulations, which have been for some time in force: 1, Stock and implements to the show to be charged full rates. 2, From the show, if sold, full rates. 3, From the show, if unsold, to be conveyed free back to the station whence they were sent, at

owner's risk, on production of a certificate from the secretary of the agricultural show to the effect that they are really unsold. 4, All the above to be carried at owners' risk. 5, Collection and delivery to be performed by the owners. 6, Regulations Nos. 1, 2, 3, as to cattle and horses, apply only if traffic be conveyed in cattle waggons and by goods trains. 7, Poultry and dogs to be charged full rates both ways. 8, No reduction in the ordinary rates for horses or cattle when conveyed in horse boxes. 9, Parties requiring the exclusive use of a horse-box for only one animal, to be charged one fare and a half.

The Secretary stated that, on the other hand, the directors of the Highland Railway Company had very handsomely agreed to carry unsold stock going home from the Aberdeen show, in horse-boxes, free of charge; and to run special trains with stock, to or from the show, if the numbers are sufficient.

It was reported that, at the recent examinations by the Royal Agricultural Society of England, the principal prizes were gained by students in the class of agriculture in the Edinburgh University, and that every one of the Edinburgh agricultural candidates took a first prize. There were twelve candidates, of whom six obtained prizes, and out of the six prize-men four were Edinburgh men, three of them having already obtained the diploma of the Highland Society.

It was arranged that the following subjects should be brought before the general meeting on the 24th June:—Election of members; chair of agriculture; Aberdeen show arrangements; agricultural education; Veterinary College examinations; letter from Board of Trade in regard to veterinary charter for Scotland; No. 3 of the fourth series of the Society's Transactions; premiums awarded for essays and reports; Dr. Anderson's report on the chemical department.

The Secretary submitted the names of 46 candidates for election as members at the next general meeting, and stated that he anticipated a much larger list before the 24th.

## THE PREMIER ON THE PRIZE SYSTEM.

A meeting was held on Monday, June 1, at Halton, a village near Aylesbury, where Mr. Disraeli inaugurated an exhibition of the industrial products of the district. The idea of holding such a display originated with Sir Anthony and Lady de Rothschild, whose seat is situate in the neighbourhood. A circular inviting the villagers to send in some article of their handiwork was issued. Any objections to so doing were met in the address, which begged them to get rid of the notion that they could not make anything. They were also specially requested to encourage their children, "as the means of showing them the road which leads to the exercise of ingenuity and taste, and to a life of honest industry; as the road which does not lead either to the public-house or to the wasteful expenditure of time or money." It was pointed out that there was an industry followed in their villages which might be turned to great advantage. They could manufacture the plait into hats and bonnets, boxes and bonnets, in endless variety of form and colour; there was also great room for ingenuity in the production of plans and machinery for the hatching, rearing, warming, and cleansing of the poultry raised in such numbers in the district. It was promised that the highest degrees of merit in each class should be rewarded by silver and bronze medals—a promise which it was found had the most beneficial effect, as the keenest interest was shown in the endeavour to win so distinguishing a mark of skill. If any fear was entertained that the exhibition would be but a small one, it was speedily dispelled; for contributions had been sent in from fifty parishes. There were five classes of exhibitors—skilled artisans and tradespeople, labourers, their wives and daughters, school-children, domestic servants, farmers and their families. Baron Lionel de Rothschild placed the grounds attached to the mansion-house at Halton, formerly the residence of Sir Henry Dashwood, but at present unoccupied, at the service of the conductors of the *fête*, and a more delightful spot could not have been found in the Vale. The spectators, numbering something like five thousand, formed a large semicircle around the steps at the entrance. In the centre were the united choirs of Halton and Aston Clinton. Behind them was the band of the Grenadier Guards, under Mr. D. Godfrey; and a company of the 4th Bucks Volunteers, commanded by Captain Selfe, did duty at once as a guard of honour and keepers of the circuit beyond which the general public could not pass. At one o'clock Mr. Disraeli took up a position on the top of the steps leading to the mansion, his arrival being greeted with a hearty cheer. The proceedings were commenced by the choir singing a "Song of Joyous Greeting."

Mr. DISRAELI, who, upon stepping forward to speak, was received with loud cheers, said: I am afraid my words will sound very flat after the sweet voices which we have had so much gratification in listening to. But I obey the commands of the lord of the manor in addressing you one moment before we witness the exhibition of the industry of our vale and its neighbourhood. Now, for a very long time, it has been considered that the good old county of Buckingham only produced butter, beef, and barley (a laugh)—three excellent things, and produced in this county in excellent style. But the fact is we have, for a very long time, been producing many other things for which we have had no credit, and to-day we are about to attempt to vindicate our reputation. I think, therefore, that when you accompany us to witness the exhibition of industry, not of this parish only, as was first intended, in its more modest and primitive idea, but of fifty contiguous parishes that have contributed the result of their ingenuity to this exhibition, you will be astonished at some of the productions, and proud of the land that has produced them. Many of you know well that there are many instances of the arts and manufactures in which this part of the world has not only not been deficient, but has even excelled. The lace of Buckinghamshire—especially of late years—has vied with that of the Low Countries; and we have produced at public exhibitions that which has rivalled with success the productions of Mechlin and Valenciennes. In one part of the county there is the manufacture of furniture carried on with

singular success, in which our beechwood is used, particularly for chairs, which we have furnished to most parts of England, and even to many of our colonies. Our embroidery will vindicate its claim to the approbation of those whom I now address. But there are also several other departments of invention in which we shall to-day advance our claims for public confidence and approval. In the first place, let me congratulate you that in this county there is so earnest a movement in order to improve the residences of the labouring classes. In this county, for several years, there has been an endeavour—and a successful endeavour—to accomplish that great end, and to-day we shall find before us specimens of invention and of design for that object which, I hope, will achieve the great end desired, and which will unite comfort and convenience with economy. There is also, I am told, one other manufacture which I shall myself witness with very great interest, and which I think you must observe with no common feelings. It is the production of an ancient manufacture in this county, though little known out of it, and not so much as it ought to be in the county itself. I allude to the silk manufacture, which not only exists but flourishes in our county town of Aylesbury. We shall witness specimens of the art of ability rarely equalled. No doubt the account which has reached me of these productions is not exaggerated, because our manufacturers in Aylesbury compete, and compete successfully, with the French makers, the goods being exported to France, where they are re-exported back to England, and then bought with admiration in Regent-street—(a laugh)—as the finest productions of the French looms (renewed laughter.) Under these encouraging circumstances we need not despair of our manufactures flourishing and increasing in the good county of Bucks. To-day there is a very great effort to recognise success in all those varied branches of industry, and to stimulate the various arts. I know not whether I am correct in enumerating the number of medals to be distributed, but I believe nearly two hundred medals will be given to-day—certainly one of gold, very many of the sister precious metal, and a considerable number of an enduring metal, which will commemorate the name and achievements of the successful competitors for these prizes. Allow me for one moment to touch upon the interesting character of the scene before us. In what could the varied classes of our complicated and admirably-devised society be better united than for purposes like the present, and for ends like those which we are all anxious to accomplish? How much better are meetings like the present than mere meetings for brutal pastime, filling a void which you have felt, and which you have desired should be supplied, but which the generosity, the taste, and the intelligence of those who should give a colour and form to the society in which they live, have hitherto been deficient in affording; I think, therefore, that on this occasion every heart must feel grateful to the generous owner of the soil for the public spirit which on this and every occasion he has shown. And in all the arrangements that during six anxious months have been matured, we must recognise the graceful thought of that lady whose taste and intelligence have diffused throughout this neighbourhood such beneficial results. I will detain you but one moment longer, and, taking advantage of the position which I unexpectedly occupy, will announce the inauguration of the Industrial Exhibition of Halton and the neighbourhood, and ask you to accompany us to witness the triumph of the industry of the Vale of Aylesbury.

The models of cottages which had been sent in by carpenters and builders were critically examined. A special circular had been issued to the competitors of this class, which stated that "greater attention must be paid to substantial and interior comfort than to outward and architectural effects." Several models were sent in, some of which possessed a good deal of merit. The general collection of articles was of a very varied character. It included a quantity of needlework, which had been executed in a superior style. The judges, who, of course, had tasting orders, spoke highly of the qualities of the articles of food, such as home-made preserves, wines, cheese, and beer.

## CANON GIRDLESTONE AND THE LABOURERS.

The anniversary of the New Inn Friendly Society, Halberton, took place on Whit-Monday. In the afternoon a large party assembled at the New Inn, where a dinner was provided by the host, who is the secretary of the Club. Canon GIRDLESTONE, who presided, said: You seem to think there is no shyness in me—that I am made of brass. Well, but I really do feel shy. As I said in the pulpit this morning, I should be glad to see some provision made, so that when a man is "past work" he may receive some 5s., 6s., or 7s. weekly, thus ending his life in quietness and comfort. Take that suggestion into your serious consideration. I have, lying on my table in the vicarage, the rules of twenty or thirty trades' unions throughout the greater part of this country, and those of each contain this important provision—when the member is "past work" he has an allowance which for the remainder of his life will keep him in comfort and happiness. I have another thing to say. I consider that as the vicar of this parish I am the shepherd of a flock, including farmers, shopkeepers, labourers, artisans, all descriptions of men, and that I am not called upon to look to one class more than another, but to do my duty to all—endeavouring, in God's sight, to promote both the spiritual and the temporal weal of all around me. The public prints say, "The parson has no right to interfere with the temporal concerns of his neighbours." Am I to be confined to the pulpit and the church? Am I, when I see you in ruinous cottages, your wives and children wanting fire and clothing, living upon miserable hard cheese and stale bread, instead of beef and mutton, such as our good host has provided us to-day—am I when I see all this to turn a deaf ear, to be so blind and hardhearted as not to notice it at all? Am I to go home to my own comforts and enjoy all the prosperity that God has given me, without making a single effort to better your position? Some persons say that the parson ought to do that. But I hold quite a different doctrine. My duty is to provide you with the services of the church in which I minister without ritualistic innovation or any other kind of innovations—to preach to you "the truth as it is in Jesus." Another duty is to look to the temporal as well as spiritual welfare of every single sheep that my heavenly Master has committed to my keeping, and, God being my helper, I am determined to do so as long as I have health and strength. This is the promise to what I am going to say. I abominate anything like violence and aggression. Most of you have probably read of the outrages committed in connection with the trades unions of Sheffield, Manchester, and other places. Nothing could be worse than that workmen should combine either against their masters—destroying their masters' property—or else against their fellow-workmen who won't join a union. But with a careful safeguard against anything of a violent character, I do think that if you agricultural labourers of the West of England, who are undoubtedly very much less paid than any others in other parts of the country, would unite one with another not to damage your masters' property, not to injure those who don't choose to unite with you, but to respectfully, civilly, courteously, with kind Christian tempers and Christian hearts, represent to your employers that you cannot on 8s., 9s., or 10s. a week maintain with decency a wife and family, and lay up against a rainy day for the time of infirmity and old age—I do think that if you stoutly unite in this manner you may undoubtedly with God's blessing attain your point. If any number of operatives in the West of England would unite for that purpose—only they had better find some one to take the lead in such a union—I will give all the countenance and assistance in my power. You must not suppose that my heart is entirely engrossed in this one particular society. I am your president, and most of you are my parishioners. But I must bear in mind that there is another club of a similar kind in this parish. In another place it has been represented that I am opposed to that club; but I take this opportunity of stating that I am as thoroughly friendly to that club as I am to this. Both have the same objects: both are composed of labouring men. I don't see why they should not be on the most friendly terms with each other: the

only rivalry between them should be who can get the most members, and who can get the largest amount of funds. For my own part I reciprocate any good feeling which they have shown me. It has been said that I invited the police to keep the "Hearts of Oak" club in order when they met last Friday. I may mention that the whole of the club, with the exception of a few honorary members, assembled on my lawn and gave my wife and family as hearty cheers as you yourselves have given me this day. If I had received an invitation to dine with the club—which I did not—I should undoubtedly have accepted it. I should have gone in the fullest confidence that every labouring man in that room belonging to that club would have protected me from the slightest attempt to insult or injure me. Every one of them as I believe has as affectionate a heart towards me as I believe you yourselves have. The police did not come into this parish to keep the Hearts of Oak in order, but to keep a few farmers in order. They came to keep in order a man who occupies the office of churchwarden in this parish. Being charged with the custody of the parish, he asked my representative on the left hand to lend him the keys of the church, and then what did he do? Without the slightest notice he had the smith at his elbow, who takes off the lock of the church door, puts it in his bag, goes to Tiverton, and gets keys made. In what a predicament I am placed! The churchyard is my freehold just as much as this house is a free house. What should I do to the man who said "Give me the keys of your house"? I should say, "Get, you fellow, out of my premises directly" (laughter). But the person of whom I am now speaking did not dare to do that. In a sneaking way he gets hold of the keys: the locks are taken off, and he gets false keys made, so that he may enter the premises at any time he chooses. I repeat that the police were called into this village on Friday, not to keep in order the Hearts of Oak, but the gentleman who, as the parish churchwarden, took off the lock of another person's property and had keys made for his own use. Understand what the parish is. This parish has 1,750 people in it; some are men, some are women; some are landowners, some are farmers and occupiers; some are tradesmen, some merchants; some are labourers. It is absurd to suppose that the parish is composed of any one class. The parish property belongs to the poorest labourer as to the richest landowner or the most prosperous farmer. My position is this. I don't wish to trespass on anybody's rights, but merely to hold tight by my own. I will not allow anybody to take from me one jot or tittle of the property entrusted to me by the law of England, of which I am the guardian and the custodian. At my tithe audit dinner I stated that I was most thoroughly disposed and determined to overlook everything past, to let bygones be bygones. I now say that I am equally determined, through good report and evil report, to maintain inviolable every single privilege committed to me by the laws of England as the vicar of this parish. In doing that I am defending, not myself, but you. A friend of mine, writing from Yorkshire the other day, said "When the men you sent me first came they could not do above one-third as much work as my own Yorkshire men do; but it is wonderful what twelve months' beef and mutton has done for them." I replied, "My dear sir, all that a Devonshire man wants when he gets to Yorkshire is a proper quantity of beef." Yea, beef suits them better than dry bread and musty cheese (laughter.) It was a curious thing that when I was preparing to meet you on the lawn I was told that a young man wanted to see me in my hall. I went to see who it was, and found an uncommon dapper spruce young man, with a watch-chain and everything complete—in fact, much better dressed than I was (laughter.) I looked down on my rusty black—that of a poor persecuted parson (laughter.) "I am," he said, "one of those who twelve months ago you sent into Lancashire"—my own parish. I answered, "Well, it appears that I did you a good turn." He had come down to attend the meeting of the Hearts of Oak Club on Friday last; he said he thought I was going to speak on the question of labourers' wages, and he should like

me to mention his own particular case. He stated that he had not been there very long before his wages were raised to £17 a-year, and everything found him. Well, his coat and watch looked very much like that (laughter.) He added, "Nothing should induce me to come back and receive the low wages of Devonshire." He had his sister with him, and was going to take his brother back. This is only one out of a great many cases. With a few exceptions the hundred men whom I have sent to different places in the country are prospering as much as I could possibly desire. I say it is for you to help yourselves. You can do so by united action, respectful, courteous

action—with no violence, no aggression. If you cannot get your wages raised in this parish and neighbourhood, do like others have done—go and seek your fortunes in better paid counties than this. I observe present my friend Mr. Grilla, who has always stuck to me like a leech; and I am sure he will agree with me, that when I advocate higher wages for the agricultural labourer, I am advocating the prosperity of the farmer himself. I have said over and over again, and I maintain it in spite of everything said to the contrary, that as the best fed horse does its work the most satisfactory, the best fed labourer likewise gives the most satisfaction in his work.

## ROYAL AGRICULTURAL SOCIETY OF IRELAND.

The monthly Meeting of the council of this Society was held in Upper Sackville-street, Dublin, Sir George Hodson in the chair. The other members present were—Hon. Charles J. Trench, Lieut.-General Hall, C.B., Charles Colthurst Vesey, John Bolton Massey, John G. Coddington, Edward Purdon, J. P. Byrne, Laurence Waldron, D.L., H. J. MacFarlane, J.P., Dawson A. Milward, Hans H. Woods, D.L., Richard Challoner, Robert Borrowes, and Rev. R. W. Bagot.

A subscription list was opened for the prizes offered by the local committee of the late cattle-show held in Stephen's-green, the council contributing £50, and the local committee £50. It was stated that the competition would be very large, and that important results would follow from so desirable an object.

The half-yearly report was submitted by the CHAIRMAN, and adopted, with some slight modification in reference to the prize offered by his Excellency the Lord-Lieutenant.

The SECRETARY read the accompanying communication, which had been received from Dr. Steele:

"Royal Dublin Society, Kildare-st., 15th May.

"My dear Sir,—I duly submitted to the council, at their meeting yesterday, your letter of the 4th inst., together with its accompanying resolution of the council of the Royal Agricultural Society, proposing joint action on the subject of the deterioration of the breeds of horses in Ireland, and I have been directed to acquaint you that the council of this society had previously resolved to address Parliament on this important matter.—I am, my dear sir, yours very faithfully,

"W. E. STEELE, Assist.-Secretary.

"Capt. Thornhill, Sec. Roy. Ag. Society, 42, Sackville-st."

Mr. WALDRON thought it would be better to have two bodies acting independently in the matter.

The CHAIRMAN said there was this peculiarity in the matter, that the word "Parliament" attached to the resolution would have the effect of taking the matter out of their jurisdiction.

Mr. WALDRON observed that it was considered if Parliament addressed the Crown to issue a royal commission it would give general satisfaction. Many gentlemen were of opinion that by acting independently it would be much better than if the two bodies acted together.

Mr. MACFARLANE remarked that as the Royal Dublin Society would not co-operate with them, he did not see why the question should not be referred to the committee to take action, and call on the Government to issue a royal commission to inquire into the whole matter.

Mr. WOODS said a committee had been already appointed, and was then in existence.

Mr. MACFARLANE believed that the Royal Dublin Society would not act with them in any matter.

Mr. WALDRON did not think Mr. MacFarlane was justified

in making such a statement, as they had at that moment a Joint Flax Committee. He repeated that in his opinion it would be better and more effective if the two bodies acted independently of each other.

Captain VESEY was not aware that on all subjects they had declined to co-operate with them. The committee might be summoned together to consider the subject.

Mr. MACFARLANE thought they should be empowered to take the necessary steps to apply to the Government at once, as it should be done in June. Power should be given them to make application at once, without calling on them to make a report to the council. He was not sorry how matters turned out; because the Royal Dublin Society having petitioned Parliament to issue a royal commission, it was time for them to apply to the Government to do the same thing, and thus strengthen them in adopting any course which they might think proper.

Mr. WALDRON believed that there was a disposition on the part of the Government to give them every assistance; but as considerable expense would be entailed, they did not like to take the responsibility on themselves. If the petition was attended with success, of course the Government would merely be the executive in the case to carry out the wishes of Parliament, that the expenses incurred would be legitimately expended.

Mr. MACFARLANE observed that the cost would not exceed \$100.

Major BORROWES said with regard to the cry of scarcity of horses in Ireland, he was of opinion that the evil would effect its own cure, because he did not think the Government could any step in increasing the number or breeding of horses in this country. If foreign governments continued to send for remounts to Ireland, they would have to give more for their own re-mounts; so that in this way the evil would effect its own cure.

Mr. MACFARLANE remarked that they merely wanted to have a royal commission issued, which would direct public attention to the breeding of horses in this country.

The CHAIRMAN stated that he was one of a deputation who had waited on the late Lord Carlisle on this point, when his Excellency told them that if any action was taken by the Government, it would refer only to the question of re-mounts.

Major BORROWES said they would find before three or four years were out that the Government would be obliged to increase the price they gave for re-mounts by a considerable amount.

The Secretary was directed to summon the horse-breeding committee together, for the purpose of taking immediate action in the matter.

The challenge cup which had some time ago been awarded to the Duke of Leinster was returned by His Grace, to be in future a perpetual challenge cup for the best description of labourers' cottages in Ireland.

The following gentlemen were balloted for and unanimously admitted members of the society: Croisdale Molony, Kilnacrandy, Co. Clare; and D. H. Cooper, Hanover House, Carlow.

The half-yearly general meeting of the society was held the same day, in the reading-room of the Farmers' Club. The Hon Chas. J. Trench was called to the chair.

The minutes of the former meeting having been read and confirmed,

Captain THORNHILL, secretary, read the half-yearly report, as follows:

"In presenting a report of the proceedings of this society during the present half-year, your council are enabled to record a considerable addition to the list of members elected during that period.

"The annual national cattle-show for 1868 will be held for the province of Ulster at Londonderry, during the last week of August next, and will occupy the site of the successful exhibition of 1868. From the untiring zeal displayed by the local committee up to the present time, your council anticipate a large and influential meeting.

"The society's exhibition of 1867, in Stephen's-green, so interesting in its various departments and carried out with so much energy and perseverance, proved most remunerative in a financial point of view; and the local committee, after payment of all the attendant expenses, having a large surplus in hands, determined to allocate a considerable sum in prizes for the successful cultivation of green crops during the present year. Your council have supplemented such prizes by the amount of £50, in order fully to carry out the recommendation of the general meeting in May, 1866, to that effect.

"In reference to the proposition adopted at the half-yearly meeting of the society, in December, 1867, that a remission of taxes, firing, and gaslights, valued at £50 yearly, should be made to the Royal Agricultural Society's Club, your council have to report that such an appropriation of the society's funds having been considered unwise and illegal by a considerable section of your members, an extraordinary meeting was convened by requisition, and was held on the 6th March last, for the purpose of taking into consideration the propriety of rescinding so much of the proceedings in December as sanctioned such allowance. The club, in the meantime, having, at a general meeting of their body, determined upon relinquishing all claim to such remission of taxes, &c., it was decided at the extraordinary meeting of the 6th March that the question be referred to the next general meeting in May, and your council accordingly recommend the rescinding of such portion of the proceedings of last December as sanctioned the remission above referred to.

"Your council are happy to report that during the past half-year much success has attended the efforts of the local farming societies in connexion with the parent one in developing the agricultural resources of this country, and that the numerous prizes awarded, in money and medals, among the farming classes are productive of beneficial results, indicating that the system of mixed husbandry is again gaining ground.

"Your council has again to express regret that more general competition has not taken place in connexion with the prizes offered for newly-erected labourers' cottages, three parties only competing in Leinster—A. Kavanagh, Esq., M.P., Mrs. Bomford, and Robert Cosby, Esq.; one in Munster—Lord Mounteagle; and for improvements in already-existing labourers' dwellings, one in Leinster—Lord Digby. Lord Digby, the Hon. King Harman, and Robert Cosby, Esq., are competitors in drainage for 1867-8.

"They have also to report, in reference to the prize offered by his Excellency the Marquis of Abercorn, for the best design of a labourers' cottage, to be erected for a limited sum, that a very large number of plans have been submitted to a committee of their body, but that, although many of these designs evinced much careful consideration of the subject, the cost of construction, according to the average rates of building in Ireland, would be in excess of the appointed limited outlay. Measures have been adopted, with the sanction of his Excellency, to allow the competition to remain open to the 1st September, 1868.

"In accordance with your 9th rule, ten members of your council retire, but are eligible for re-election. A correct list of members whose subscriptions have been paid to 1st of April has been prepared, and forwarded to each member entitled to receive it.

"Annexed is a statement of receipts and expenditure for the past year, as audited by Messrs. O'Connor and Molloy, who kindly gave their services gratuitously.

"Signed, "GEO. HODSON, Bart., Chairman.  
"J. BADHAM THORNHILL, Sec."

Examined, and found correct.

CHARLES C. VESSEY.  
H. J. MACFARLANE.  
PHINEAS RIALI.

21st May, 1868.

We have carefully examined the above accounts, and compared the vouchers with the items, and we find them to be perfectly correct.

VAL. O'B. O'CONNOR.  
ROBERT MOLLOY.

Lieut.-General HALL moved the adoption of the report, which appeared to him to be very satisfactory indeed.

Sir GEORGE HODSON seconded the motion, and in doing so observed that it was unnecessary that he should refer particularly to any topic noted in the report which has just been read. It might be thought suitable, however, that he should say a word or two in reference to the paragraph which related to the appropriation of a portion of the society's funds for the use of the Royal Agricultural Club. That paragraph had been carefully considered and attentively worded, and he sincerely trusted that the meeting would adopt it without discussion and without dissension. There had been a good deal of feeling displayed in the matter, but he did not think there was anything in the paragraph with which the most sensitive could find fault. The club, they were aware, had relinquished the claim put forward for an allowance for rent and taxes, and the council had considered it proper to accept their offer, declining to receive such allowance; and they now wished them to

adopt the report, which rescinded, to a certain degree, so much of the proceedings of the former general meeting as sanctioned that appropriation. The adoption of it, he thought, would restore to them a good deal of peace and tranquillity, and give effect in the main in inducing Lord Clonbrock and his co-trustees to continue as trustees of the society (Hear, hear). It would also enable them to approach with better attention the main objects which the council and the society had in view—that of promoting agricultural science in this country.

The CHAIRMAN said, before he put the resolution, he thought it was a question whether it should not be followed by a resolution absolutely rescinding what had been done at a previous meeting.

Mr. BYRNE conceived that if the motion for the adoption of the report was put from the chair, it should be acceptable to all parties; but, if anything else were put forward, there might be others who would canvas it out of doors. The paragraph was drawn up in order to promote that harmony and kindly feeling which it was right and necessary should exist in a society like that. The club had agreed to those terms; and if the acceptance of the report, in its present shape, was acceptable to the meeting, it would tend to the cordial agreement of parties outside.

The CHAIRMAN remarked that it appeared to him, as Chairman, that it was not quite satisfactory, inasmuch as some members who had not paid their subscriptions might not do so, as they would say that the resolution had not been rescinded. A short resolution, rescinding the previous one, was, he thought, necessary.

Sir GEORGE HOBSON wished to say, as a member of the council, that it was not in the province of the members to do more than recommend the general meeting to rescind the resolution in question. They had no power to do anything

final in the matter. They, therefore, sent it forward as a recommendation; and if the report was adopted, he did not see why it should not be considered sufficient to answer all the purposes.

Sir JOHN DILLON insisted that the resolution referred to should be decidedly and absolutely rescinded by the meeting. He had been always opposed to it from the beginning.

Mr. WALDRON said the question before the chair was the adoption or rejection of the report. It might be competent for anybody afterwards to move such a resolution as that which the Chairman spoke of. He apprehended that their duty was to adopt the recommendation of the council or not, as they thought fit.

The CHAIRMAN then put the resolution, which was carried unanimously.

Captain VESSEY moved that, in compliance with the recommendation of the council, the resolution relative to an allowance of £50 to the Agricultural Club, passed at the half-yearly general meeting, be rescinded.

Mr. HANS WOODS seconded the motion, which was carried.

Mr. WOODS proposed a vote of thanks to Messrs. Molloy and O'Connor, for having kindly audited the accounts of the society free of charge.

Sir JOHN DILLON seconded the resolution, which was passed.

On the motion of Major Borrowes, seconded by Mr. George Woods Maunsell, Messrs. Townsend, Millward, and Byrne were appointed scrutineers to take the ballot for the election of members of the council.

The following is the result of the ballot: Hans H. Woods, Sir John Power, Bart., R. M. Carden, P. J. Newton, Lord Powerscourt, John Borthwick, C. U. Townsend, Lord Lurgan, Sir Richard Musgrave, S. A. Richards.

## EAST SUFFOLK CHAMBER OF AGRICULTURE.

A meeting of this chamber was held at Ipswich. The president, Mr. F. S. Corrauce, M.P., was in the chair. The attendance was limited, there not being 30 members present.

Mr. W. JOHNSON (Boyton), vice-president of the chamber, introduced the first subject—The Condition of the Agricultural Labourer. He said: At a Conference held in March last in Willis's Rooms upon the condition of agricultural labourers a series of resolutions were passed for the proposed remedy of imaginary grievances, and with those resolutions farmers generally differed. The object of the meeting was to take into consideration three questions: "What are the causes of the unsatisfactory condition of the agricultural labourer?" "What are the best means calculated to improve that condition?" "If by the formation of a society, then upon what plan should such society be constituted, and what steps should be taken to form it?" In the first place, he was not disposed to admit that the present state of the agricultural labourer was so thoroughly depressed as was represented. He was prepared, from an experience of more than 30 years in this county, to state, without fear of contradiction, that he never knew the agricultural labourers in East Anglia in a better position than at the present time. At the same time he was unwilling that it should be inferred that he was not willing to enter into the consideration of the desirability of improving the comforts and condition of the agricultural labourers, for he would be glad to do anything to improve their condition; but he did not wish to admit that they were so oppressed and persecuted as it was endeavoured to be made out. The Rev. Canon Girdlestone stated that the poor people were expected to bring up their families upon 7s. or 8s. or 10s. a week. They knew nothing of such wages in Suffolk, and consequently the question of wages did not apply to their case. Canon Girdlestone said that he had been instrumental in raising the wages from 7s. to 10s. a week; but in this part of the country they ranged from 12s. to 15s., and therefore with the question of wages they had nothing to do. Mr. Johnson then referred at some length to the proceedings at Willis's Rooms, and proposed a resolution condemnatory of the resolutions passed, which, after some observations from the chairman, was taken as carried.

The Hon. Sec., Mr. H. BIDEELL, said he had received a long letter from Col. Adair, upon the subject of County Financial Boards, from which he read an abstract.

Mr. JOHNSON said: It was unnecessary for them to discuss the details of Mr. Wyld's very voluminous bill, it having been withdrawn, and they had simply to consider the principle of the measure, which would require very few words, the justice of the attempt having been admitted by the Government, although the Bill was rejected and a committee appointed to inquire into the working of county business generally. Committees were very slow travellers, and very often were appointed for the purpose of postponing measures, so that nothing more might be heard of them, and consequently it was necessary that this committee should be reminded that the country was watching their proceedings. Hitherto county business had been confined to the county magistrates, and he was not going to say a word of complaint or disparagement of the conduct by the magistrates of that business, for he believed they were anxious to investigate and control the expenditure to the best of their judgment; but as the county expenses affected real property generally, the ratepayers claimed a right to superintend them. The question was, what was the most advisable step to take? He would not propose anything ponderous or complicated like Mr. Wyld's Bill, because if there were a large financial committee the result would be too apt to be a great deal of talk and very little work. He at the same time believed the magistrates would gladly accept the assistance of other parties, men of judgment and experience, to co-operate with them on financial matters. He took up this question with no feeling of opposition to the magistrates, and would much regret that the magistrates should imagine that there was any feeling of antagonism to them, for the desire was simply to co-operate with them in solving the different problems that might be brought before them. They had been told that these matters were purely landlords' questions, and that all charges on land finally fell on the landlord; but he had yet to learn how to divide the interests of the tenant and the landlord, for he considered they must be identical. It was a great mistake to attempt to divide the interests of landlord

and tenant as to divide those of the employer and the employed, and he regretted that there were not more landowners members of that chamber. He moved

"That this Chamber views with approval the principle embraced by the bills upon the County Financial Board. The application of that principle is, at present, a matter of apparent difficulty; but this Chamber begs to record its opinion that these difficulties are not such as ought, in its opinion, to present an insuperable obstacle to the just settlement of this question."

Mr. R. L. EVERETT said, as representative of that chamber, he was present at the last meeting of the council of the Central Chamber in London when this subject was discussed. One gentleman strongly condemned the reference of the subject to the House of Commons to a committee, as shelving the question; but Mr. Wyld denied that such was the case, and it seemed that Mr. Wyld had been so unfortunate as to draw an impracticable bill, and one the details of which his own friends did not like.

Mr. G. TOMLINE, M.P., believed that if the system were changed it would not be found more economical; but if it should not be more economical, still they would have the satisfaction of spending their money themselves and knowing how and why they spent it. But he did not stop here—he went further, and said the magistrates would thank them for giving them the power (if it should turn out that by Financial Boards they did give it) of resistance to those central authorities to which allusion had been made—power of resistance to government inspectors and government departments, who liked to throw every burden, even those which were almost imperial as well as those which were local, upon the rate-payers. He had been told by the Lord-Lieutenant that a circular had been sent round to Lord-Lieutenants asking their opinion whether the magistrates would consent to borrow on the security of the county rates a very large sum for the purpose of building barracks for the militia when called up for their training, and stating that when those barracks were built with money borrowed on the security of the rates, then Government would consent to pay a rent for them. But Government had no power to pay a rent, because the money which was to be applied in payment of rent must be voted by Parliament. However, this secret circular had been sent to Lord-Lieutenants asking their opinion as to the probability of the magistrates assenting to the imposition of this new burden. Now if that circular had been sent by the Home Office to County Financial Boards, if they existed—he would not pre-judge the question and say whether they would assent to the proposition or dissent from it—the rate-payers would be treated with a certain degree of courtesy and respect in their representatives being asked whether they were willing to have a new burden imposed on them, and whether they were inclined to borrow a large sum for the erection of those barracks, the expense of which ought not, in his opinion, to be thrown upon one species of property, the owners of that species of property having no power at this moment to criticise or condemn this new demand. There was proof enough that this secret system of departmental government was burdensome upon rate-payers, and magistrates might thank them if by esta-

blishing County Financial Boards they gave them the power of saying "no" to such demands. In West Suffolk, he saw by the newspapers, the magistrates were acting with great courage in respect to the gaol inspector, that a new gaol should be built, and he said the establishment of County Financial Boards would do the magistrates a service in giving them the power to say "no" to burdens, the imposition of which they could not now resist. The circular he had alluded to was an argument for Financial Boards, &c. He did not think the Lord-Lieutenant, who was by his office the representative of the sovereign, was a proper person—nor even would the High Sheriff, as representative of the freeholders, be the right person—to communicate with on the subject of the finances of the county. Let them have a Financial Board, who would know what was proposed, who would openly discuss it, and who might, as they pleased, say "Yes" or "No."

Mr. HERMAN BIDDELL could not understand why, if there was no opposition to the principle involved in Mr. Wyld's Bill, but only objection to the manner in which it was drawn, the whole matter should have been referred to a committee. It appeared to him the only principle involved was, "Are the ratepayers to be represented in determining upon the collection and disbursement of county funds? or is it to be left in the hands of those who have for years had the management of it?" All agreed that the ratepayers should be represented, and why should it be referred to a committee to inquire into the working of certain matters? The ratepayers never asserted that the funds were misapplied or mismanaged; all they said was that they were altogether disregarded in the matter. He could not see the necessity for a committee, and regarded it as an attempt to shelve the matter.

The PRESIDENT said he must call their attention to the circumstance that they had only discussed the principle of a bill for establishing County Financial Boards, and that the details remained untouched. They had not heard anything from anyone with reference to what such a bill ought to be, and there was a wide difference between the mere admission of a principle and the determination of details. He was not a Government apologist, but they would allow him to say a few words upon the debate on Mr. Wyld's bill. There was an entire unanimity among the speakers with reference to the principle, but scarcely one speaker approved of the way in which it was applied. The bill was cumbersome; it went into a great deal more than Parliament would, at one sitting, be prepared either to discuss or decide upon, and it opened all sorts of principles. Mr. Biddell had said that committees were very often the grave of good measures, but they were also often the grave of very bad ones, for of all bills introduced into Parliament the larger proportion were utterly to be condemned, and for one good bill ten were introduced so bad that if their authors had been tolerably discreet they never would have seen the light. Therefore he approved of sending the bills to a select committee, more especially such a bill as that in question. When they came to examine the details they would find this was not such an easy thing to apply.

After some further discussion the resolution was assumed to be carried, and the meeting broke up.

## SOMERSET CHAMBER OF AGRICULTURE AND COUNTY ASSOCIATION OF RATE-PAYERS.

The fourth general meeting of the members of this association was held at Bridgwater, when Mr. J. P. BROADMEAD, of Enmore, was voted to the chair.

The CHAIRMAN said, that this was not merely a meeting of the Chamber of Agriculture, but also of the "County Association of Ratepayers," and consequently it affected all classes of persons who were liable to pay rates. He repeated they must be very thankful to the gentlemen connected with the Yeovil Board of Guardians for having moved in this important matter. They might not be prepared to concur in all the minor details to which the chamber had committed itself, and, moreover, they were not asked to do so. The promoters of the association merely said if they could agree that the general

principles laid down were sound and good then they could join it; and he thought quite the same. It had been thought by some that it was merely the claims of the Chamber of Agriculture which they met to advocate; but such was not the case—they were also an association of ratepayers, and as such dealt with matters affecting every class of persons. If they considered the system upon which the poor-rate was levied at present, and what was really proposed by this association, they could not fail to see that those who are now unfairly burdened would be greatly relieved by the personal property of the country being called upon to contribute, as it ought to do, towards the rate for the relief of the poor, and all those various other charges which he had named. They did not ask to be

relieved of any burthen which it was right and just for them to bear; they wanted to have everything fair, and that was the object of this meeting. Some persons argued that money in the funds should be exempted, because at the time the funds were established money was required for carrying on a war, and there was a kind of compact that the capital so invested should be free from rating. But at that time we had no police or highway rates, and many of the barthens now complained of had not been imposed upon them. Therefore, these things being altered, all things might be altered. He urged them to move in this matter, for if they did not they could not expect that those who were not at present rated would come forward voluntarily and offer to bear their proportion of these charges. They might feel that in justice they ought to do so; but of course they would say, "Let those who are interested in it move in the matter; we are not going to do so." If they did not put their shoulder to the wheel they would not get relieved. An impression seemed to prevail that they wanted to transfer all these burdens to trades and manufactures; but it was not so, for by including all personal property in the assessment they would be benefited rather than oppressed. After all it was but fair that those who obtained their wealth from the labour of the poor, should, when these had become indigent and unable to work, help to support them; whereas at present the poor, whose best labours were employed in the aggrandisement of the wealth of the manufacturing interest, were thrust back upon the landed interest for support, whilst those who had reaped the advantage of their labour contributed nothing towards the rate. He appealed to the meeting whether the system was not an unfair and unreasonable one?

Mr. ANDREWS, as secretary of the association, explained more fully the objects and purposes of the meeting.

Mr. JOHN TRASK proposed "That this meeting fully approves and endorses the resolutions passed by meetings of this association held at Yeovil, Taunton, and Bristol." He remarked that the resolutions referred to had been circulated, and no doubt every one present was conversant with them.

Mr. JOHN SAMSON seconded the resolution, and it was carried by acclamation.

Mr. T. BAKER, of Boroughbridge, proposed "That this meeting pledges itself to use every effort to make the objects and purposes of this association known throughout the county of Somerset in accordance with the circulars and resolutions sent to the guardians of each parish, and addressed to the ratepayers." He moved this resolution because he highly approved of the movement and the broad principles upon which the association was based. He believed the time had come when the rating system should be thoroughly and completely overhauled and re-adjusted.

Mr. JAMES KINDER, in seconding the resolution, hoped that the matter would be taken up in thorough earnestness, and he had no doubt their efforts would be crowned with success.

The motion was unanimously carried.

Mr. R. S. PITTARD proposed, "That in the opinion of this meeting a persistent attempt should be made by the chairmen and committees of the associated ratepayers in each union to get every town and parish in their union represented by a ratepayer, and to canvass for members and subscriptions."

Mr. J. STUCKEY, of Drayton, seconded the resolution, which was carried.

Mr. H. G. ANDREWS proposed, "That in the opinion of this meeting the ratepayers of parishes, independent of subscriptions from large proprietors, should attempt to raise the income of this association to £1,000 a-year, and that this can be done with ease in a field consisting of 510 parishes."

Mr. REYNOLDS seconded the resolution, which was carried by acclamation.

Mr. JAMES FRY proposed, "That the secretary be requested to convey to Sir Massey Lopes the thanks of the Somerset Chamber of Agriculture and of this meeting for the able way in which he has brought the question of Local Taxation before the House of Commons."

The motion on being seconded by Mr. FRITH was carried.

## THE PENWITH AGRICULTURAL SOCIETY.

The annual exhibition of the Penwith Agricultural Society, which has now attained the age allotted as man's sojourn upon earth—three score and ten—has been held at Treneere, Penzance. A finer show of cattle and horses for a local meeting has rarely been seen; and some good judges expressed it as their opinion that it would take some unusually fine cattle to beat the first-prize shorthorns, exhibited at the above show. In making their awards to the horses, the judges had a most arduous duty to perform, and they were a considerable time before they succeeded in awarding the prizes to their own satisfaction. The horses were tried in every way, and in the presence of a large number of spectators, and it was generally admitted that they gave their fiat in favour of first-class horses. The show of pigs was certainly not large, but what was deficient in quantity was in every respect made up in quality. The contest in this department was between Mr. E. Bolitho and Mr. Sydney Davey, two gentlemen who have competed in former years. Last year the first prize was carried off by Mr. Bolitho, and this year the same gentleman was again successful, Mr. Davey being second; but he was disqualified from taking the second prize in consequence of his having won the same prize last year. There was an excellent exhibition of sheep, and the Leicester rams were especially noticeable for their size and beauty. The judges were: For cattle, sheep, and Pigs—Messrs. Luke Bice, St. Enoder; Jabez Steeper, St. Columb; and Marshall, Maidstone, Kent. For horses and implements—Messrs. J. Burgess, Barncoose, Illogan; Whiteer Laming, Treveethoe; and R. Quick, Trewellard St. Just. The following were the

### A W A R D S.

#### CATTLE.

North Devon Bulls.—First, G. Mason, Truro; second, J. Burgess, Barncoose.

Shorthorn Bulls.—First and second, Hosken & Son, Hayle; third, S. Harvey, Sennen.

North Devon Bulls, calved since January 1st, 1867.—First, T. Stevens, Wendron; second, G. Mason.

Shorthorn Bulls, calved since January 1st, 1867.—Second, Hosken & Son.

North Devon Cows.—First, J. Burgess; second, J. Mason.

Shorthorn Cows.—First and second, Hosken & Son.

Cows of the Guernsey or Jersey breed.—First, R. F. Bolitho, Ponsandane; second, H. Hodge, St. Levan.

Cows of the cross-breed.—First, E. Bolitho, Trenuggo; second, Rev. M. N. Peters, Penzance.

Two-years-old Shorthorn Heifers.—First and second, Hosken & Son.

Heifers of the Guernsey or Jersey breed.—General Tre-menhoe, Boscathnoe.

#### HORSES.

Stallions calculated to improve the breed of saddle horses.—First, W. Hawke, Budoek (Sea King); second, J. Yeo, Bod-min (Gazna).

Stallions calculated to improve the breed of horses for general purposes.—First, Hosken and Son (Forester).

Stallions calculated to improve the breed of cart-horses.—First, H. Laity, Clowance (Goldfinder); second, H. Roberts, St. Hilary (Oxford).

Brood saddle mares with foals.—First, J. Abraham, Crowan; second, G. Eustice, jun., Hayle.

Three-year-old fillies or geldings for the saddle.—First, S. Harvey, Trevar; second, N. Hoskins, St. Allen.

Three-year-old fillies or colts for general purposes.—First, Branwell and Sons, Penzance.

Two-year-old colts or fillies for the saddle.—First, W. Jelbart, Roborough, Devon.

Two-year-old colts or fillies for general purposes.—First, J. Bone, Penzance.

Cart-mares with foals.—First, Branwell and Son; second, J. Pearce, St. Buryan.  
 Yearling colts or fillies for the saddle.—First, H. Laity.  
 Yearling colts or fillies for general purposes.—First, J. Chapple, Sancreed.

## SHEEP.

Leicester rams.—First, J. Rosewarne, Nanspauker; second and third, J. Thomas, Phillack.  
 Leicester hogg rams.—First, second, and third, J. Rosewarne.  
 Five Leicester ewes.—First and second, J. Thomas.  
 Five Leicester hogg ewes.—First, W. Laming, Trevethoe; second, J. Rosewarne.

Southdown rams or other Down.—First, S. Rodda, Penzance; second, R. F. Bolitho.

Five Southdown ewes, or other Down.—R. F. Bolitho.

## PIGS.

Boars.—T. Thomas, Sancreed; second and third, S. Davey, Redruth.

Sows in farrow, or having had farrows.—First, E. Bolitho, Trennuggo; second, J. S. Davey.

## HUSBANDRY IMPLEMENTS.

£3, Messrs. Holman and Sons, for the best assortment of implements, particular mention being made of the corn horsehoe and the liquid-manure distributor.

## THE RABBIT QUESTION IN COURT.

A case involving the question of law as to damage to growing crops by rabbits came before the Court of Common Pleas on June 1st. Mr. Gatacre, the landlord, appealed against a decision obtained by Mr. Woodbrick, his tenant, in the County Court of Shropshire. The case stated that the plaintiff in the court below was tenant to the defendant under a lease containing a proviso excepting all game, which was reserved to the defendant as owner of the land. Adjoining a field so held by the plaintiff the defendant had a coppice, which was full of rabbits, and the rabbits got into the plaintiff's field, and so injured the crops, that in 1865 the defendant allowed him £75 as compensation for the damage done by them. The rabbits were for a time kept down, but since then they had greatly increased, and inflicted damage on the tenant's away-going crop of last year to the valued amount of £21. The defendant offered the plaintiff £12 as compensation, which he refused to receive, and brought his action in the Shropshire County Court to recover the amount of the estimated damage, and the learned judge of that court gave judgment for the plaintiff for the amount claimed, against which was the present appeal.

Mr. Archibald appeared for the appellant, and Mr. Hudson for the respondent.

For the appellant it was contended that the action would not lie, that the rabbits were *fera nature*, and that the appellant was not responsible for what they did. Suppose a fox had gone out of the coppice, was the appellant to be held responsible for its taking his neighbour's chickens? The respondent was restricted by the terms of his lease from killing the rabbits when on his land, but that was by his own agreement. He referred to "Jeffries v. Evans," 34, *Law Journal Reports*, C. P., page 51. The learned counsel was here stopped.

For the respondent it was contended that the decision of the court below was right. Half the respondent's crop had been destroyed by the rabbits which issued out of the appellant's coppice, and it was his duty to keep down their increase, so that they should not be a nuisance to his neighbours.

The Chief Justice: Are the rabbits the property of the appellant?

Mr. Hudson: The appellant ought to have kept down their increase.

Mr. Justice Byles: They are the most prolific of all animals.

The learned counsel, conceding that, still contended they had no right to consume the respondent's away-going crop, and that the appellant ought to have taken means to prevent it.

Mr. Justice Willes: Have you looked into the civil law on the subject?

Mr. Hudson said he had not. He had thought it was more a question of the common and statute law.

Mr. Justice Willes said if the learned counsel would consult the civil law, title *Actio noxalis*, he would find it had much bearing on the matter.

Mr. Hudson said he had not referred to that head of the civil law, and proceeded to contend that the rabbits were a nuisance, and had wrongfully been permitted to increase.

Mr. Justice Willes referred the learned counsel to the old case, in the year books, of the bear, which while tamed and in captivity rendered its master liable for its acts, but having regained its liberty and escaped into the woods it committed all manner of atrocities, for which its former master was held not liable. In the present case, had these been tame rabbits, the case might have been different. So also there was the case of *Dale v. Edwards*, where a person kept a dog which had a propensity to go out on his own account, and went poaching into a preserve, and killed the pheasants, where it was held that an action lay against the owner of the dog; that case had carried the law to the extreme. It seemed to him that this action was an utterly groundless one.

The learned counsel said the decision in this case was that of Mr. Josiah William Smith, a very learned judge.

The Chief Justice wished to treat the decision with every respect, but it was the decision appealed against, with no authority to support it. The appellant was not the owner of these rabbits in any sense to make him responsible. There was no contract, expressed or implied, in the lease, that he would keep in or kill down the rabbits. The judgment must, therefore, be reversed.

This decision leaves the matter in a very unsatisfactory state for the farmers, who suffer by the overstock of game, which there is no question is the case in some parts of the kingdom. Taking Essex generally we do not think the tenantry have much to complain of in this respect—though of course there are some lands that do suffer from this cause; and most of the occupiers have a little of the sporting spirit in them, and look rather with pride than displeasure to a fair stock of game in their fields and hedgerows. But in other districts of the kingdom the manner in which the game is preserved is a serious loss to the tillers of the soil, and the rabbits are a nuisance, for though the owners of the land do not care much about the latter, where these are the perquisites of the gamekeepers, as is commonly the case, those gentry look jealously and closely after them, and take care to have a good stock in hand.

This decision, which places the rabbits on the same ground as the sparrows on the house-top, is therefore a grave matter to many, and will require the serious consideration of the tenant in taking, and a liberal arrangement on the part of the landlord in letting, a farm.

## THE STATE OF AGRICULTURE IN THE UNITED KINGDOM.

At the last meeting of the Maidstone Farmers' Club Mr. ELVY read a paper on "The state of Agriculture in the United Kingdom, and its relation to the safety of the Nation." He said: I have to introduce a subject to your notice which is one that is perhaps rarely taken up by farmers. My motive in bringing this subject before the club may be deemed presumptuous; if it be, I can only plead my wish that it may lead men of far greater consequence and ability to consider the matter. I have been led to think, by seeing in *The Mark Lane Express* and other papers, the probable chance of England wanting corn before the arrival of the harvest. Now, if such an event is likely to take place during a time of profound peace, with the ports of all the world open to us, what may be the case prove if war, or any other evil, shut off our supplies? Our fleet, which has for "a thousand years braved the battle and the breeze," is indeed an arm of strength, and ever may be England look proudly to it. But not even to such a tower of strength should we trust for a supply of food. We, in some measure, resemble ancient Rome. She, like us, conquered and colonized, and at last depended for her supplies of food more on foreign lands than her own. Corn, &c., was obtained more cheaply from other soils: thus her own were neglected, and the Pontine Marshes were allowed to run to waste and become swamps. Brigands there find a shelter, and thus prove a curse to Rome, as well as a fatal misgiving arising therefrom. These evils may not be feared; but a short supply of corn is by no means improbable, and what would be the state of London, and of our great cities, with their over-crowded populations, if suffering from the want of the necessities of life? We know too well how unmanageable they are. Let us then consider how we can make ourselves as safe as we can, and try to meet an evil even before it arrives. Looking back to the state of agriculture centuries ago, we find that the United Kingdom did not produce a fifth of its present amount. Yet then it produced enough to feed its inhabitants. Now, with all its increase, it needs immense supplies of foreign grain, &c. Population has so largely increased that it has outgrown the land. Agriculture has made rapid strides, but cannot keep pace, at least with its knowledge. What are we to endeavour to do? how obtain a greater supply? As the land now yields three or four times as much as it did in the days of the Edwards and Henrys, can it not be made to yield far more, and thus ensure our safety? We have now the advantage of chemistry; we have manures from cloth and other factories: we have guano; the knowledge of herbs and plants converted into manure. We learn that by a change of crops, by keeping our land clean, fallowing is rendered generally unnecessary; by grubbing all useless hedges and trees, taking in all straggling land, we are enabled to increase our acres, as well as throw our land open to the sun and air. We have also the knowledge of machinery. Where these acts have not been done, let them be so. Let prejudice be put aside, let men be taught their own and their country's welfare; let, also, liberal leases be granted to good tenants, and let them be encouraged to render the land fruitful; let, also, rabbits and hares be placed at the disposal of the farmer. I come now to what I deem more necessary than even the before-mentioned ways of increase. Let no man talk of indolence or idleness. Our Great Creator, when he formed man, made him to live agreeably to his will; and let no fastidiousness curl up its nose at the organs God ordains him to live by. See with what infinite wisdom it is ordained that all we eat or drink, all we wear, even our bodies, can be returned to the earth, and so fructify it that it will reproduce what has been consumed. This is a fact well known to scientific men—nay, even to most agriculturists. Why, then, should not production go on with consumption? Why, because we waste and destroy the means. Thus our towns are rendered unhealthy, our rivers polluted, when that which poisons them might be rendered a blessing. It might not, in the language of the world, repay individuals or corporate bodies, but surely Government might aid in so good a plan. Deep cesspools might be formed, into which all the excreta might run. They might be covered

over to prevent smell by evaporation, and the contents sold for manure. There is a new invention—earth-closets—a plan of which I have before me. These we are now using at the Union, and I believe they will supersede water-closets, &c., in many places, and be the means of easily effecting the purpose of retaining animal manure. Dr. Monckton, in his able paper, to which I had not an opportunity till lately of paying proper attention, urges greater attention to agriculture, though he does not openly state the necessity; yet both he and Mr. Mechi bear me out in pressing it on the public. Let the farmers of England change sides with the public, and extend protection to those who refused it to them. Let us humbly look on the earth in a religious point of view. The Great Creator made it beautiful to man, and from its bosom fruits and flowers sprang, untilled, uncultivated. Man, by his disobedience, brought the thistles and weeds, and what then seemed to be a curse upon the ground. But, even then, in His severity, the mercy of God held out a remedy: "Thou shalt labour, and by the sweat of thy brow shalt thou raise thy bread." There was health and happiness in the command. Man has found health and content; he has restored, by that labour, the earth to its fertility; fruits and flowers have again sprung forth, and thus man only obeys the command of his Maker when he applies all his diligence to the cultivation of the earth.

A letter was here read from Messrs. Haynes and Sons with regard to the use of earth-closets, and the advantage which they had proved on their own premises and elsewhere.

Mr. HAYES said he could fully endorse what Messrs. Haynes said, as he had used a similar closet on his own premises, and found it to work admirably. There was still, however, great prejudice to be overcome in the matter, as he had found that labourers had refused to use them. He thought they were greatly indebted to Mr. Elvy for bringing the subject forward, not only as farmers but as Englishmen. No doubt the question of feeding the people concerned every one in the country. Mr. Elvy had touched two points in his paper which were received with cheers, and therefore he imagined his views met with their approval. The questions were the providing of greater security to the tenant, and that their lands should not be overrun with game. According to the agricultural statistics issued lately, the population was twenty millions, and the acreage under wheat three millions two hundred thousand in round numbers. He had no doubt that if expense was not considered, one-half or two-thirds of the wheat land could be made to yield very much more than it now did. But then, under present circumstances it would not pay. The tenant was suffering from want of capital, and he wanted greater security given for what he did, and the destruction of the crops by hares and rabbits avoided. No farmer would object to give reasonable and fair sport. Might the time never come when country gentlemen could not find fair sport. But there was no sport, in his opinion, in shooting down flocks of game as if they were barndoor fowls. It was frequently said that he who could make two blades of grass grow where one grew before was a benefactor to his country; and he thought the opposite was also true, that he who prevented two blades of grass growing where one grew before—that any landlord who refused fair security to the tenant, and who allowed his land to be overstocked with game—was not a benefactor to his country, but quite the contrary. He did not wish to see any legal remedies introduced, for he thought over-legislation was a great evil. But all that they could do to call the attention of the country to those defects, by making their voices heard, he thought they ought to do.

Mr. BRIDGLAND (the Chairman) said he thought the question of game was one entirely between the landlord and the tenant. A farmer took his land with his eyes open, and he made his own bargain. He thought, however, they should try to get rid of the annoyance of the ground game, hares and rabbits.

Mr. HAYES said he wished to see the land produce as much as it possibly could of the food of the people. He

spoke not as a farmer, but as an Englishman. He thought no reasonable man would object to a fair, old-fashioned style of shooting, but he did not think it was right that the farmer should have the produce of his fields destroyed by vermin.

Mr. HODSOLL said he thanked Mr. Elvy most cordially for the manner in which he had introduced the subject. He held, however, that the produce of the land contributed but in a small degree to the safety and the welfare of the nation. It really was the subdivision and distribution of labour which contributed so powerfully to the prosperity and safety of this realm. What was it that enhanced and created the value of the produce of the soil but labour? What was the flax which they produced worth until it was dressed and woven and spun? What was the value of metals—of even gold itself—until labour had been applied to it? They would pay, perhaps, two guineas an ounce for an elaborate article in silver, the raw material of which they could buy at 5s. It was true that a great deal of wealth first emanated from the soil, but it was distributed through various streams in which manufactures and commerce took part, and so built up the colossal power and wealth of this kingdom. When Mr. Elvy spoke of Rome and the Pontine marshes, and suggested that England might possibly decline in a similar manner, he forgot that the position of the two countries was entirely different. Rome never encouraged a subdivision of labour, and the extension of commerce and manufactures, so that that country could trade with others, and the wants of one nation could be supplied from the over-productions of another. He was satisfied that, as long as commerce and manufactures existed in England in their present state, we should find markets for the products of our skill, and have plenty of money to purchase of the foreigner the supplies of food we required. But he did not ignore any of Mr. Elvy's conclusions with regard to agriculture. There was nothing to prevent them from producing two blades of grass where one grew before, but everything to encourage them in doing so. Every penny we laid out in corn was so much abstracted from the wealth of this country; and, therefore, the question of liberal leases and matters of that kind ought to be considered. Mr. Hodsoll concluded by calling upon both owners and occupiers of land to assist the efforts of the West Kent Chamber of Agriculture to obtain, without further delay from the legislature, through their representatives, a more fair adjustment of local taxation, which, he said, was only secondary in importance to the increase of their crops.

Mr. T. REEVES, jun., said he fully concurred in what Mr. Hayes had said, that the want of security and the game were the two great things at the present time that hindered agriculturists from progressing. They should be encouraged

to make the land of England produce more than it does now. Mr. Hayes had said that if the present acreage of wheat were made to produce one quarter more than it has previously done, it would feed the population of the country for three weeks. But he said that the acreage of wheat planted at the present time might be made to produce three quarters per acre more than it does now, and that would feed the country for nine weeks. The question Mr. Elvy had introduced was very important as to the safety of the country. If they did not take care of themselves, they would find themselves in a position they would all deplore: and it was for the landowners to look about them and see what was for their own interests as well as for the interests of the agriculturists. They might have increased rents if they would give proper security to their tenants, and do away with their greatest curse, the game, for there was no doubt that it was a curse to them. The question of small enclosures was another matter that should receive the serious attention of them all. In his neighbourhood they saw enclosures of one, two, and two-and-a-half acres surrounded by trees, where there would be but a small patch in the middle where they could grow anything. Then the drainage question was a matter of great importance to them. He believed that the interests of the agriculturists had been too much ignored by the commercial class for many years, and if they had been better upheld by them they would have been in a very different position, and have had more money to have spent upon such improvements, while the commercial class would have been none the poorer. There had been, he considered, too great a tendency in the legislation of late years towards the commercial interests, and ignoring almost—if not entirely—the agricultural interests. The commercial interests would never serve England in the event of famine; neither their money nor goods would feed the people. If at any time the country should be at war with more than one nation, they would find it very difficult to get food for the inhabitants, and, therefore, they should stir heaven and earth, as it was said, at the present time to increase the produce of the land in the country. He was convinced that the produce might be doubled in a few years if the proper steps were taken. If they went through the country they would see all round the fields places that would not produce nearly as much as the middle would. Then came the question of hedgerows and timber, and the game that lived in the hedgerows devoured what sprang up. On that account they would find that in the Weald of Kent the produce of many farms was not one-quarter of what they might be made to yield in the course of some three years.

The discussion was continued for a short time after this, but with nothing of moment in it.

## TOPDRESSING.

At the dinner of the Wester Ross Farmers' Society, Mr. ADAM said: I may say that top-dressing is an operation with which our forefathers were little, if at all, acquainted. It is an operation that has become common in these later years through the importation and manufacture of such large quantities of portable manures. Our forefathers would have given to their land with right goodwill, I doubt not, all the manure they could scrape; but with guano, nitrate of soda, and the endless diversity of stuffs with which we are now familiar, they knew nothing; consequently, their crops, having had applied to them beforehand all the disposable manure, had to go on to harvest unsupplemented, unassisted by any addition, and depended exclusively on the sunshine and rain from heaven. We, in this respect, are now-a-days more advantageously circumstanced. In addition to the ordinary farmyard manure, we not only can give, when sowing the crop, a supply of artificial manure, but even after the crop is braided, should there be any appearance of sickness of the plant, any indication of stunted growth, a manure easily dissolved, and readily washed to the roots of the plants, we can apply with immediate and astonishing effects. In this respect, the farmer stands somewhat related to the plant as its medical attendant. His practised eye detects the first symptoms of

disease, by fading colour and lagging step; but, assured of the cause of disease, the fitting manure is applied with the desired result of the restoration of the beautiful hue of health, and of greatly-accelerated growth. The necessity of topdressing arises from the soil being imperfectly supplied with the constituents necessary for the growth of plants. Did the soil naturally contain an inexhaustible supply of all that the plants required for their growth, then manure, either ordinary or artificial, would never be needed. But it is well known that very little of the soil of our country is fitted naturally for the full development of our plants; and it is equally well-known that soil, thus naturally fertile, speedily becomes, by continuous cropping without manure, so reduced and impoverished as to exhibit only the shadow of a crop. The large proportion of the soil of our country is naturally so barren that, when improved, it will grow nothing until supplied at a great cost with plant-growing substances. Indeed, the first outlay in clearing and breaking up ground is often small as compared with the outlay necessary in bringing it into a state of ordinary fertility. But a state of ordinary fertility is not all that is desiderated. What the improving tenant is desirous of, is to have his land in that condition in which he might reasonably anticipate the largest possible yield. True, there are a few favoured spots in

such a condition as this; and to apply topdressing to these to increase the return would be the height of folly, as it would in all likelihood result in a crop early laid and in a diminished return. To apply additional manure to soil already sufficiently supplied with every necessary ingredient, is similar to bringing an additional round to the dinner-table after all the guests are choke-full. But farms in such a state as this are rarer than angels' visits. I once saw, and perhaps only once, 2 cwt. of Peruvian guano given to one acre over and above the supply given to the field generally, without the slightest perceptible difference, either at the hoeing or lifting of the crop, simply because the field had a sufficiency of manure without this addition—there being over 32 tons of turnips per acre. It is not every day that one will stumble on a farm off which a yield could reasonably be expected of 6 qrs. of wheat, 9 qrs. of barley, and from 10 to 11 qrs. of oats per acre, and these are Mr. Mechi's maximum returns. If these returns have not as yet been reached by us, is there not room for top-dressing? and if they have been reached by us, is there not need for abundant manuring still, to keep the ground in a condition in which it can continue to give a return so magnificent? Whether such returns as these can ever be reached as a general rule it is impossible to say, but I am persuaded that ere the soil be brought to its highest possible state of cultivation much has to be learned and much has to be done. The kinds of manure that are more generally used for top-dressing purposes are guano, nitrate of soda, and dissolved bones. Until within these few years guano was more commonly used, but, from the fall in the price of nitrate of soda, it is now coming more generally into use, and from its facility of solution, it is very easily washed into the soil. To specify any one kind of manure as the best for top-dressing purposes generally would be unwise and misleading. The kind of crop to which it is to be applied, and the nature of the soil in each particular case, must be fully considered, and the manner adopted thereto must be selected. To all our cereal crops, top-dressing in ordinary seasons, if wisely applied, will be advantageous. True, in such dry summers as we some time ago had, top-dressing was of little or no value; whilst in dry shallow soils it was really disastrous, greatly assisting the drought in its withering effects. But fortunately such seasons as these are the exception, not the rule, and without somewhat of the prophetic spirit cannot be foreseen. To grain crops the quantity to be applied must be carefully considered, as it now and then happens, when nitrate of soda is largely used, that there grows an abundance of straw, but the grain may be nearly entirely wanting, and when this happens the straw is inferior also. A large dose may be much more safely applied to grass, either for pasture or hay, as there is less regard to the growing of seed than to the quantity of grass sown, and hay secured. The season I have found most suitable for topdressing is spring. Even to autumn-sown wheat it is more advisable to apply topdressing in spring than when the grain is sown; for I have found, when applied in autumn, that the manure very much exhausted itself in forcing on an undue growth in winter and early spring, which was again cut down by the later frosts, leaving the wheat in a worse condition than it would have been if it had received no topdressing at all. To wheat and grass, topdressing may be applied at any time in spring, care being taken, however, that the soil be not too wet, so that the manure would be in danger of being carried away, and that there be rain either at the time of sowing or the prospect of its immediate coming thereafter, so as to secure that the manure be washed into the ground as soon as possible. Topdressing of oats and barley is more conveniently applied at the time of sowing the grain. Could present prices of grain, or something even considerably lower, be stereotyped, then there could be no question of the profitableness of topdressing; but should prices fall to nearly one-half their present amount, which we have sometimes seen, it might yet be advisable to topdress, if not for the value of the additional grown grain, yet for the increased quantity of straw raised, which would be so helpful in maintaining or improving the general condition of the farm.

Mr. MIDDLETON said that he topdressed different ways almost every kind of crop, and generally he found himself benefited by it—perhaps not so much as he would desire, but still to an extent that he considered remunerative. The soil on his farm was easily overdone, and therefore he had to topdress carefully. The mixture he preferred for corn crops was

dissolved bones and guano, with a little nitrate of soda. For hay he found guano best, with a little both of nitrate of soda and bone meal.

Mr. BETHUNE said that he generally topdressed his grass every year with nitrate of soda and guano; for his corn crop he used guano chiefly. He never tried nitrate of soda or dissolved bones for his corn crop, and of the guano he usually gave from one to two hundredweight an acre.

Mr. SIM said it had been remarked that the man who made two blades of grass grow where one grew before deserved the thanks of mankind; and he considered that the farmer who top-dressed judiciously would almost accomplish this feat. One thing, however, they all ought to learn, and that was, to mix manures properly; for sufficient attention was not usually paid to this important point. In corn crops, a great deal depended on judicious mixture, so that they might not find a handful of nitrate here, a handful of dissolved bones there, and a handful of guano in another place. He found the following mixtures answer best in his own experience: For wheat, one hundred-weight of nitrate, a half-hundredweight of Peruvian guano, and one hundredweight of superphosphate have the best and most lasting results; and I think the proper time for application is just when the fresh growth sets in in spring. Barley, of all other grains, is the most dangerous to topdress, as, if too quick and luxuriant a growth is induced, you are apt to have soft straw and a lodged crop. He found two hundredweight of best superphosphate most suitable, harrowed in with the seed. Oats, on strong land especially, repay topdressing more than any other grain, as it ensures a strong, quick growth at once, and in dry seasons prevents the crop from becoming set after the strength of the seed is exhausted. He found one hundredweight guano and two of superphosphate most beneficial. Of all crops, the most marked results of top-dressing are produced on potatoes. He found last year, by actual experiment, that it increases the crops by one-fifth; and, in talking the other day to a farmer (who has been a regular grower of potatoes for years), as to the quantity he gave to his potatoes, he told me he never used less than six hundredweight per acre; and he believed it would pay to give more. He found Peruvian guano one hundred weight, potash one hundred weight, and best dissolved bones two hundred-weight to suit him best, two-and-a-half hundredweight put down when planting, and one half-hundredweight when earthing up.

Mr. HOSACK said he had not top-dressed much; but he tried it last year, and he had nearly two-thirds—at least fully one-half—more crop on the part that was top-dressed than on the other parts of the farm. The mixture he used was a hundredweight of nitrate of soda, two hundredweight of superphosphate, and two hundredweight of salt. The soil was very strong clay. He considered that top-dressing was remunerative.

Mr. AKRES, whose experience of topdressing in Roxburghshire was asked, said that he had not yet had very much experience of it, but he had tried it on grass and oats, and in both instances the result was most extraordinary. In regard to the oats, the thing he noticed was that while the rest of the field was very dirty, the part topdressed was comparatively clean, as well as the crop produced being much heavier. By topdressing grass he found the crop improved about one-half; on the other hand, the faggage or grazing was not so good, but the second year the grazing was quite as usual, if not better. The faggage, however, was not nearly so good, especially with nitrate of soda; with Peruvian guano and bones it is not so bad. In Roxburghshire, topdressing was not carried out to a great extent, because the land had not much body in it. He mentioned as an experiment on one occasion that two acres of light soil were topdressed in the middle of a field, and another two acres, not topdressed, were carefully measured off. In the part of the field topdressed the crop became quite flat, and, on being thrashed out, it was found that there was a dead loss of six bushels an acre, compared with the piece not topdressed.

Mr. FENTON said that on all ordinary land judicious topdressing was, in his opinion, beneficial. He recommended as a good mixture two cwt. of salt and two cwt. of nitrate of soda, half-cwt. of Peruvian guano and half-cwt. of super-phosphate; he had found this suit very well both for grass and corn. He advised every one to use two or three cwt. of common salt; it strengthened the straw, and likewise kept it supple.

Mr. ROSS said he had got his farm in very bad condition, but by using a good deal of Dingwall manure he had brought

it into such excellent order that he was afraid to topdress it. He found that so long as he could grow very nearly  $8\frac{1}{2}$  quarters of wheat to the acre he did not require to topdress.

Mr. HARPER: Don't make last year a criterion.

Mr. PETERKIN said that on the farm he occupied before he came to Ross-shire the soil was generally light, and he had to apply a good deal of artificial manure. What he found answer best was a cwt. of guano, a cwt. of super-phosphate, and a cwt. of nitrate. He remembered on one occasion topdressing a grassfield of 25 acres, and giving it of nitrate alone about two and a-half or three cwt. per acre. He had an extraordinary crop of hay, perhaps not less than 300 stones to the imperial acre, and it was thinnish soil; but next year he had nothing. After that he never topdressed with nitrate alone, but used the mixture he had mentioned, along with a cwt. of salt. On the land he required to dress for oats, he often laid down the manure (got from fishing villages, &c.) in September or October, or if not then in spring, and found very great benefit arise from that method. Topdressing, he thought, had always

paid him. As he had said, a great part of his land was thin, and yet he had always had as good crops as others with better land. He considered the farmer should always topdress, especially if he had not such land as their friend Mr. Ross; on the good alluvial soil, such as many of them had about Dingwall, he considered that top-dressing was beneficial.

Mr. HARPER said that topdressing had puzzled him a good deal, and he did not think that his experience was of any authority. The year before last he topdressed a dry field with guano, super-phosphate, and bones, but he was obliged to use extraordinary measures to keep the crop down, and he partly lost it. When in Edinburgh a gentleman to whom he was speaking had told him that nitrate of soda had nearly ruined him. He had a good crop the first year, but the next he had none at all.

The CHAIRMAN then summed up, giving it as his opinion that with proper attention topdressing would pay all farmers. The result of the discussion was that guano, nitrate of soda, and bone meal were considered the best top-dressing mixtures.

## THE WORCESTERSHIRE CHAMBER OF AGRICULTURE.

At a meeting, Mr. G. Whittaker chairman, a letter was read from the secretary of the Central Chamber, requesting the secretary to forward to Mr. Jasper More, M.P., the chairman of that Chamber, the names of any gentlemen this Chamber would like to give evidence before the select committee of the House of Commons on the subject of Financial Boards.

The CHAIRMAN said he thought that perhaps they would have some difficulty in proving their case, but they wanted to show that, if they had Financial Boards, the moment any bill came before Parliament affecting the interests of the ratepayers, the ratepayers on those Boards would immediately oppose that measure, and show to the country that the bill would increase the burdens of the ratepayers.—Mr. BLICK confirmed what had been said by the chairman, and added that with regard to the Lunatic Asylum the magistrates had to carry out the provisions of an Act of Parliament, under the supervision of the Lunacy Commissioners. The management of the gaol, too, was now by a special act placed in the hands of a joint committee of city and county magistrates, subject to the supervision of inspectors appointed by the Home Office; and in a discussion at the Central Chamber of Agriculture it was stated that the magistrates had very little control over county expenditure.—Mr. ABELL remarked that that might be so, but they never found the Government and the magistrates coming into opposition. In nineteen cases out of twenty the alterations were suggested by the magistrates.—A discussion followed, in the course of which Mr. GUEST said he did not think Mr. Wyke's bill went far enough. He thought that the ratepayers could elect all the members of the Board. It was true that they had a great many good financial men sitting as magistrates, but the principle they wanted to do away with was "taxation without representation." A few years ago, at the time of the alterations at the gaol, there were magistrates put upon the Gaol Committee who were not business men. When they got such men on committees they were induced to lay out money without due regard to economy.—Mr. WEBB said that in his district the magistrates had no adequate interest in the matter of expenditure. There were two or three farmers in the neighbourhood who had to pay more rates than all the magistrates put together.—Ultimately it was agreed that Messrs. Whitehair, Webb, and Blick (secretary) be appointed to represent the Chamber.

Mr. BLICK reported that the period for which the *Chamber of Agriculture* was ordered to be supplied to the members of the Council had expired, and he wished to know if it was to be continued.—Several members of the council complained that the reports of the various meetings of the Chamber had not been reported, and Mr. WEBB proposed the following resolution, which was agreed to:—“That the secretary of this Chamber request the editor of the *Chamber of Agriculture* to supply copies of that journal for the next two months for the members of the council, and at the same time state that in the

opinion of this Chamber the reports of the meetings of the Central Chamber have not been as full and satisfactory as they could wish, and also to call his attention to the fact that meetings of this Chamber are sometimes omitted, although he has been furnished with the necessary information.”

The SECRETARY mentioned that Mr. Dillwyn, M.P., had introduced a bill “to amend the laws relating to the holding of fairs in England and Wales.” He had written for copies of the bill, which he expected in a few days.

The CHAIRMAN said that, at the last meeting, it was pretty well agreed that they should call a general meeting of the Chamber to consider the subject of local taxation. He considered it the most important subject that had come before them for some time, and he had a notion that a public meeting would go a good way towards ventilating the subject. A long conversation ensued as to the desirability of having the public meeting immediately or postponing it for some time, and this was decided by the following resolution, proposed by Mr. ABELL and seconded by Mr. SMITHIN, being carried, “That a public meeting be held this day fortnight on the subject of local taxation, at half-past eleven o'clock.”—The resolutions to be proposed at this meeting—three in number—were then discussed and agreed upon.

At the meeting of this Chamber, Mr. G. WHITTAKER, chairman,

Mr. TRINDER moved, “That this Chamber, having taken into consideration the great and continued increase in the poor-rates, and local taxation generally, is of opinion that the present system of rating is unequal and unjust.”

Mr. RUSSON seconded the resolution, which was put and carried.

Mr. B. SMITHIN moved the second resolution as follows: “That income arising from personal property ought to contribute with real property to a national rate.”

Mr. WHITEHAIR seconded the resolution, which was carried.

Mr. JAMES WEBB moved “That an income-tax, properly levied, will afford an economical means of taxation, and this Chamber will use its best endeavours to bring about a system of national rating on that basis.”

Mr. J. ABELL seconded the motion.

Mr. WILLIS-BUND objected to the income-tax being mentioned. He thought they would have great opposition to any scheme for taxing personal property, and their endeavour ought to be as much as possible to disarm opposition. The income-tax was a very unpopular tax, and the very name of it would create opposition.

Mr. WEBB, in reply, said he thought that the difficulties suggested with regard to taxing real property could be got over by a national rate being levied, and out of that the amount of the precepts of each union paid.

Mr. RUSSON supported the resolution, and contended that

they ought to be supported by both the borough and county members.

The CHAIRMAN expressed his regret that on the present occasion they had so few landowners of the county of Worcester endeavouring to pull with the tenantry for an adjustment and equalisation of the burdens upon land. It appeared to him that, although the landlords did not pay the taxes, and they fell upon the tenants, if they did not mind it would eventually fall on the landlords. He was very much surprised that the large landed proprietors of this county should take so little interest in the welfare of their tenants. It was time that all parties connected with the land should lend an assisting and helping hand to promote the one cause. There was no wish to put class against class, or tenant against landlord, and he was sure that the tenantry of the kingdom were not opposed to the wishes or the interests of the landlords, but they did feel, and felt justly, that burdens crept on time after time which had to be borne exclusively by tenant-farmers. With regard to Mr. Willis-Band's observations relative to the income-tax, he could not agree. He did not think they had anything to apprehend from adopting the income-tax; it was not for them to suggest the mode of legislation. Mr. Pearson had suggested one remedy, and Mr. Webb another, the latter gentleman suggesting that a proportional amount be paid out of the Consolidated Fund; but he would not detain the meeting by dwelling on these subjects, as it was so simple a matter. He would, however, say that he did not think the adoption of this course would at all do away with local government. This Chamber was not a political one, and he hoped it never would become political, but where matters of interest to the tenant-farmer was concerned it was their duty as a class to insist on the county members attending in their places in the House of Commons and voting on all important clauses. He thought that on Mr. Wylde's Bill to establish Financial Boards it was their duty to have attended, but the fact that only twelve county members were present on that occasion did not show that they took a deep interest in the affairs of the farmers. He thought that when any vital subject was brought forward they (the Chamber of Agriculture) would not be doing their duty if they did not write to the borough and county members to beg of them to support any measure which the Chamber might think ought to be passed.

The CHAIRMAN then put the motion, which was carried.

#### THE WESTERN CHAMBERS OF AGRICULTURE.—

At a meeting at Falmouth, during the Bath and West of England show week, Mr. Brydges Williams in the chair, the subject of poor-rates and local taxation, and a motion which Sir Massey Lopes brought before the House of Commons a short time since, were discussed, and the following resolutions passed: Sir Massey Lopes, M.P., proposed, and Mr. Whevenen seconded,—“That it is the opinion of this meeting that the direct tax of eleven millions per annum now levied under the name of poor's rates bears unfairly on income arising from real property; and that the exemption of income arising from personal property is not only unjust, but also impolitic and prejudicial to the public interest.” Proposed by Mr. H. G. Andrews, and seconded by Mr. Peter,—“That, whereas the majority of ratepayers in towns are deeply interested in the removal of the exemption from poor's rate of income arising from personal property, means should be taken through the medium of the several Chambers of Agriculture in the Western counties for uniting their co-operation in this movement.” Mr. H. G. Andrews said that at a meeting of the Somersetshire Chamber, held at Bridgwater on the 27th of May, he was deputed by that Chamber to present the following resolution to Sir Massey Lopes: “Resolved, that the thanks of this meeting be given to Sir Massey Lopes, M.P., for the able manner in which he has brought before the House of Commons the present unjust exemption from poor-rate of income arising from personal property.” The Chairman said that the meeting could not do better than follow the example set by the Somerset Chamber. He would therefore propose that the best thanks of this meeting be given to Sir Massey Lopes for having treated the subject with so much ability, and having given so much attention to that important question.

#### THE MORPETH CHAMBER OF AGRICULTURE.

The usual monthly meeting of this branch was held at Morpeth, Mr. Thos. Bell in the chair.

Mr. THOMAS LAWSON, of Longhurst Grange, having read a short paper on local taxation, Mr. J. ANGUS moved, and Mr. T. LAWSON seconded, “That this Chamber strongly recommend the council to send at least one witness to give evidence before the Select Committee of the House of Commons upon the present system of county finance, and that such witness specially bring before such committee the expenditure of £2,250 in the purchase of premises adjoining the Moot Hall Courts, for the sole purpose of removing the danger which might accrue to such courts in case the aforesaid premises took fire; the said Moot Hall Courts having always been regularly insured against fire.”

Mr. JOHN MOOR moved, and Mr. JOHN RUTHERFORD seconded, “That the local rates press severely on the landed-interest, and that this severity arises by a large amount of property of a local description being exempted from assessment, and that in consequence not one-half of the property ability within a parish is assessed to the relief of the poor.”

Mr. YOUNG moved, and Mr. MOOR seconded, the following: “That many matters of rather national than local purpose have been added to the local rates, and that such ought, in whole or in part, to be repaid to the local treasurer from the national treasury.”

Mr. RUTHERFORD moved, and Mr. ANGUS seconded, “That there is no subject of greater importance, or more immediately requiring the full consideration of the general council of the North of England Chamber of Agriculture, and that our local council members be requested to press the council to take such steps as will define what would be a more equitable assessment of local property for local purposes.”

**EAST RIDING CHAMBER OF AGRICULTURE.**—At the ordinary monthly meeting of members at Beverley, Mr. W. Bainton presiding, on the motion of Mr. Langdale, seconded by Mr. C. Dixon, the chairman was selected as a witness to be examined before the House of Commons Select Committee on the disadvantages of the present system of county finance. A very lengthy discussion then took place by adjournment, on a paper read by Mr. R. W. Parke, of Catwick, at the last meeting, relative to the present system of rating. After two hours' debate, Mr. Parke proposed “That it is the opinion of this meeting that the maintenance of the poor, highways, police, and militia falls unfairly upon real property alone, and that all property and income whatsoever ought to contribute its reasonable proportion.” Mr. A. Crosskill and Mr. Norfolk objected to a division taking place at that hour, as two-thirds of the members had left the room. The objection was overruled, and the motion was carried by 12 against 7.

**A CURE FOR THE RABBIT COMPLAINT.**—Farmers never make a greater mistake than when they allow their worst farming to be round a wood. It is precisely there that should be the largest expenditure in cake and corn, and the greatest amount of manure. Farmers ought to be made aware, if they are not now, that when we have heavily folded a piece of white or red clover, the sheep having been well supplied with cake, corn, malt combs, bran, and hay, the second growth will be so rich and rank that it will kill many sheep, whether lean or fat, and is almost certain death to lambs. This applies equally to rabbits. The same remarks apply in degree to pasture or Italian rye-grass, for I dare not sewage-manure the first or spring-growth when it is intended for sheep and lambs. They cannot stand such rich food, nor can the rabbits. A friend of mine who farms 1,200 acres told me an amusing story about this. His bailiff was desirous to have some rabbits in a grove, to which my friend waggishly assented. His fat sheep were closely folded and heavily caked round the grove, and the rabbits soon departed this life. Those who intend following my example of close-folding will do well to take note about the dying of sheep as well as of rabbits. I have a great respect for pheasants and partridges; they can hardly be too numerous, and are the farmers' best friends. Of course the pheasants should be fed in covert.—J. J. MCHT.

## HANTS AND BERKS AGRICULTURAL SOCIETY.

## MEETING AT WINCHESTER.

The show of this society took place on June 5. The entries almost in every class showed an increase, though in some few of the subdivisions there was scarcely what could be called keen competition. The cart-horses, although not numerous, included some excellent animals; and some were descendants from previous winners at these meetings. Among the mares in-foal there was nothing very striking, but the mares as a class were very good. The cattle presented some moderately good specimens, more especially amongst the cows; but perhaps the exhibition was chiefly remarkable for the sheep shown. The Hampshires were particularly noticeable for their splendid quality, and one of the judges—Mr. Saunders, of Watercombe—declared he had never before seen such sheep; and some Cotswolds sent in by Mr. Tombs, of Lechlade, Gloucestershire, deservedly attracted much attention. In pigs there was a marked improvement on the show of two or three years since as to number, variety, and quality, and that they were excellent will be at once manifest when we say that a sow sent by the Marquis of Ailesbury, winner of a Bath and West of England prize, came off here with third prize, and was, though of splendid quality, admittedly inferior to those placed before it by the judges. There were in all only three "hunting horses." The show of agricultural machinery was large; made up as this was by Tasker, of Andover; Wallis, Haslam, and Stevens, of Basingstoke; Sutton, of Shirley; Burgess and Key, of Newgate-street; The Reading Iron Works; Brown and May, of Devises; Gower and Son, of Hook; H. and G. Kearsley, of Ripon; Fitt, of Bishopstoke; Taylor, of Headbourne Worthy; Samuelson, of Banbury; Watson, of Andover; and Bradford, of Fleet-street, London.

There was a trial of grass-mowers, all the machines being drawn by two horses. The competitors were—The Reading Iron Works; Woods, of Upper Thames-street, London; Samuelson; Hornsby, of Grantham; Burgess and Key; Howard, Bedford; and H. and G. Kearsley, Ripon; but the majority of the machines entered were in the hands of local agents. One acre of clover and rye grass was cut by each, and the prizes were awarded thus:—1, Woods (48 min.); 2, Howards (52 min.); 3, Burgess and Key (76 min.). These three had an additional trial in order to place them, after being selected as the three best. The work was considered to be very good.

The dinner under the presidency of Lord Northbrook was but thinly attended, and the proceedings were rather tame; Mr. Beach, Mr. Bonham Carter, and Mr. Barrow Simonds, the three M.P.'s present, keeping carefully clear of "Farmers' Politics."

## PRIZE LIST.

## SHEEP.

**HAMPSHIRE, OR WEST COUNTRY DOWNS.**—Ewe Tegs not separated from the flock.—First prize, a cup, value 10 guineas, J. Warwick, Martyr Worthy; second, £5, G. K. Budd, Cliddesden, Basingstoke. Highly commended, J. Warwick. Commended, W. Pain, T. and M. Arnold, W. and J. Cordery, and J. Reeves.

Ewe tegs not separated from flock before 1st April.—First prize, a cup value £5 5s., J. Barton, jun., Hackwood Farm, Basingstoke; second, £5, G. K. Budd. Highly commended, W. E. Fitt, Littleton.

Ewes of any age.—First prize, a cup value £5, F. S. Schwann, North Houghton; second, 50s., J. Rawlence, Bull-bridge, Wilton. Highly commended, J. Palmer, Cliddesden. Commended, W. Pain, W. E. Fitt, and J. Wigg.

Rams of any age.—First prize, £5, R. Coles, Middleton Farm, Norton Bavant, Warminster; second, 50s., J. Moore, Littlecott, Pewsey. Highly commended, W. F. Bennett, Chilmark, Salisbury. Commended, J. Moore, and T. and M. Arnold.

Shearling Rams.—First prize, a cup, value £10 10s., E. Olding, Ratind, Amesbury; second, £5 5s., S. King, Bockhampton, Lambourn; third, £3, S. King. Highly commended, A. Morrison, Berwick, Tisbury; J. Parker, Lasham, Alton.

Ram Lambs.—£5 5s., A. Morrison; £3, L. Lewis, Chilton Candover. Very highly commended, G. Edney, Whitchurch. Highly commended, J. Moore and A. Twichen. Commended E. Cole, G. Edney, F. S. Schwann, W. F. Bennett, J. Barton, jun., and E. Olding.

Rams of any age.—First prize, a cup, value £5 5s., C. Child, Lower Wyke; second, £2 2s., J. Warwick. Highly commended, J. Warwick.

Ewe Lambs.—£3, J. Warwick; £2, G. R. Budd.

**SHEEP OF ANY OTHER BREED.**—Rams of any age.—£5, J. K. Tombs, Langford, Lechlade, Gloucestershire; 50s., T. B. Brown, Salperton Park, Andoversford. Highly commended, J. Wheeler, Long Compton.

Shearling Rams.—A cup value £5, J. K. Tombs; 50s., J. K. Tombs. Highly commended, J. K. Tombs.

Ram Lambs.—£2, Mrs. Clift, Shereborne St. John; £1, Mrs. Clift.

Ewe Lambs.—£2, J. Atkins, Barton, Peveril; £1, H. Portsmouth.

Ewes of any age.—£5, J. Atkins; £1, J. Atkins.

Ewe Tegs.—£2, H. Portsmouth.

Fat Lambs.—£3, W. E. Fitt.

## CART HORSES.

Stallions.—£5, W. H. Gale, Manor Farm, Burbage, Wilts; 50s., J. M. Earwaker, Peak Farm, Warnford. Commended, W. E. Fitt.

Two-year-old Stallions.—£3, R. Gringham, Shalden; 30s., R. Gringham.

Mare and Foal.—£5, J. G. Attwater, Britford, Salisbury; 50s., W. B. Stubbs, Tichborne, Alresford. Highly Commended, J. Atkins. Commended, Messrs. Follett.

Cart Mares.—£5, F. M. Ross, Fobdown, Alresford; 50s., F. B. Bailey, Brown Candover; £1, F. M. Ross. Commended, F. R. Hulbert.

Three-year-old Filly.—£3, J. Atkins.

Two-year-old Filly.—First prize, W. Woodward, Owalebury, Winchester.

## HUNTERS.

£5, R. P. Fitzgerald, North Hall, Preston, Candover; £3, J. Canning, Sutton Scotney.

## CATTLE.

Shorthorn Bulls.—£4, J. Atkins; £2, J. Taylor, Headbourne Worthy.

Bulls of any other breed.—£3, J. Turvil, Hartley, Alton; £2, E. Curtis, Dummer Grange.

Two-year-old Bulls of any breed.—£3, J. Atkins; 30s., W. L. W. Chute, The Vyne, Basingstoke.

Yearling Bulls.—£2, T. R. Hulbert, Old Alresford.

Cows in milk.—£3, J. Turvil; £2, Mr. C. Charlwood, Padworth Mill, Reading. Commended, W. Goodall, Winchester.

Heifers under three years old.—£2, C. Charlwood; £1, W. Nicholson, Basing Park, Alton. Highly commended, J. Atkins, J. Turvil.

Heifers under two years old.—£2, J. and M. Arnold, Westmeon; £1, C. Charlwood. Highly commended, J. and M. Arnold.

## PIGS.

Berkshire Boars.—£4, H. Humfrey, Kingstone Farm, Shrivensham; £2, H. Humfrey; £1, J. H. Clark, Attwood, Maidenhead.

Berkshire breeding Sows.—£3 and £2, H. Humfrey; £1, the Marquis of Aylesbury.

Boars of any other breed.—£3, Captain R. P. Warren, Worting House, Basingstoke; £2, J. Wheeler, Long Compton, Shipton-on-Stour. Commended, Capt. R. P. Warren.

Sows of any other breed.—£3 and £2, Capt. R. P. Warren. Commended, T. Baring, M.P.

## EXTRA STOCK.

Highly commended, Miss Taunton, Stockbridge, for shorthorn cow; commended, T. Chamberlayne, for three pigs 14 weeks old; C. Charlwood, for shorthorn heifer; A. C. Sayers, Bishopstoke, for a cow.

The Judges were—*Sheep*, T. Saunders, Watercombe, Dorset; G. Butler, Tufton, Whitechurch; and J. Allsopp, Wellow, Romsey. *Horses, Cattle, and Pigs*, J. B. Spearing, Beaham Lodge, Reading; J. White, Odham; and W. C. Spooner, Eling. *Hunters*, W. W. B. Beach, M.P., and J. Deacon, Master of the H.H. *Poultry*, J. Bailey, Mount-street, Grosvenor-square, London. *Mowing*, J. Lancashire, C. Hart, and E. Portsmouth.

## TO FALMOUTH AND BACK.

BY A PRACTICAL FARMER.

I must confess that the primary reason of my visit was the circumstance of the show being held in a part of the country I had not yet visited. I had been to Exeter and Torquay, but no further—hence my desire to pass through Devonshire into and through a considerable part of Cornwall. I was greatly delighted with my journey down. My first day's journey from Waterloo Station ended at Plymouth. The country through which I passed down to near Basingstoke is comparatively uninteresting—wild heaths, desolate and dreary; bad land, and worse farming. Energy, intelligence, and capital only are requisite to improve most of it. Much of it is undoubtedly bad enough; but in these days of abundance of capital, and no great lack of enterprise, the wonder is that it remains unproductive so long. In getting into Wiltshire I was truly struck with the remarkable improvements manifest since my visit to "The Royal Meeting" at Salisbury, 1857. It may be the season—it may be my fancy: be that as it may, I was much pleased with the satisfactory prospects everywhere before me. The crops on all sides were nearly clean (only a few yellows here and there), and almost all good. The sainfoin crops unusually plentiful, clean and good—the grass seeds very promising—the fallows forward and cleanly. In the breeding of cattle and sheep I could occasionally notice signs of crossing, or attempts, as I thought, to improve their breeds. This is as it should be. The chief end of migratory societies is to import or introduce the knowledge of departmental agriculture, and excite native energy and talent wherever they go. Beyond Salisbury I soon got into some very pleasing and fine dairy districts; but as I had no opportunity of taking notes, and evening was coming on, I reserved my remarks thereon till my return. I reached Plymouth too late to notice the district. The town itself is most interesting: The Hoe is unsurpassed by anything I have seen. My next day's run down to Falmouth was rapid and interesting in the extreme; but as I purposed taking agricultural notes of my journey on my return, and was enabled to do so, I give them as they struck me on, so quickly passing. I left Falmouth at 10.10 a.m. We were soon in the country; and at Penryn, about two miles from Falmouth, the land along our route clean and well farmed; over viaduct No 1 country exceedingly pretty; the hills very steep, and valleys narrow and deep (apparently, as we passed along, averaging from 200 to 500 or 600 yards in width, and chiefly laid upon wood frame-work), and positively looking dangerous to pass over. The fields are very small, surrounded with hedges, not cut into shape, but laid in some fashion on the banks on which they stand. More beautiful valleys; arrive at Perrenwell-station. The bridge or viaduct fine! Presently a mining district on our left; small paddocks, too small for fields, on our right, with hedges round and timber; now some heath, and over a long viaduct very high, and then through a cutting to Truro, which is beautifully situated, surrounded by richly-wooded hills and still richer valleys, deep and picturesque, with a pretty river flowing through it. The grass fields small, but rich in verdure, and nicely grazed, chiefly with dairy stock. No crops to any extent. The church on the hill to our left very imposing, and extremely rich. The stock seen along our route chiefly shorthorn cattle and Leicester sheep. The town is almost beneath us, we being upon a long and high viaduct. Some crops of wheat. We soon pass into a high and poor

country, along a bank, then a tunnel, then a bank, and into a fine country on our right, well-farmed. The stock, shorthorns and Leicesters. We keep passing fair crops and good seeds; the soil now free, now strong; the crops, wheat, oats, and barley. The soil now looks like a stony, gravelly district. Reach Grampound-road—now a slaty soil; the farming still good. A small flock of rams. Now viaduct after viaduct; then a cutting; get amongst mines, and in a higher country, and broad, with larger fields; the seeds and farming good. Now into the white clay district, i.e., "decomposed granite." Much is raised and sent to the potteries. On our left a fine country comes in, and a view of the sea to the right. We noticed that the implements seen are poor and very homely-made. Saw establishment for stamping ore, &c.; pass two viaducts, high and very fine, overlooking it. Austel: We are now getting to a high elevation, and travel nearly along the tops of hills, with most richly-wooded valleys below us, all extremely beautiful for many miles together, and nicely grazed or in meadow: the country to the right very undulating—now in a cutting, now a view of the sea; field with much garlic; now amongst the mines—tin—krolin. At Par-station: much white clay shipped from hence to various countries, as well as to Staffordshire. We pass along steep hills, and over romantic valleys, to a better country, and well grazed—to Lostwithiel. The soil clay or clayey loam, grass lands abounding in buttercups. The fields far too small, with big hedges and trees: the sheep Downs, and the cattle Devons. We pass along the country: extremely pretty grass-seeds; good Leicester and Down sheep here. The rich woods and varied foliage of a park, with nice residence near Bodmin-road station, are very fine. We are at a great elevation: country wild, and abounding with mines. The hills higher: we are dragging hard—now upon a high viaduct, about three hundred yards over a beautiful dell, extending to our left and far below us. Now another viaduct, very deep: the hills on our right not cultivated, but on our left good farming; now wild again—our viaduct over the tree-tops. Another remarkably deep—all trees under us again; another still deeper and narrower. These narrow gorges, spanned by these wondrous viaducts, created singular emotions on passing. They don't appear to average above two hundred yards in length, and the depths must be from one hundred to two hundred feet. We now go along the hill-sides: the country to the left very fine. I never saw such a succession of deep viaducts before. We arrive at Doublebois-station. We are soon along some fine land, fairly farmed, and notice Devons, Shorthorns, and I thought a small flock of Cotswolds and Cotswold lambs: again over a very fine viaduct. Liskeard: again a fine viaduct and fine hill. Menheniot station—a nice country now—Devons and Leicesters. The soil a sort of slate stony loam, of singular appearance. The roads mended with slaty stone; viaducts again long and high; country more expansive and good—quite a relief to get away from the little crowded fields, the hedge-row timber almost meeting across them, to their larger fields well-farmed and growing good crops: noticed mangolds given to some fine lengthy sheep. We soon reach St. Germans; all very fine. Now come to the river, clothed with beautiful trees to the water's edge. A park or beautiful wood opposite, all very rich. The river, along which we rattle, broad and very attractive. We soon ap-

proach Saltaash, with its wonderful viaduct. The woods and scenery of Mount Edgcombe from this point is very fine.

I would here observe that amongst the answers to many inquiries I learnt that flock-masters never wash their sheep prior to shearing, and that the average difference in price of washed wool is from 4d. to 5d. per lb. I learnt that landlordism is at its height in Cornwall. On many estates the tenant must not destroy a rabbit; no, not for his own table! nor any game; that rabbits are sold by landlords by 200 or 300 couples together; that the tenant must give twenty-four days' notice before he can plash a hedge, so that the steward, with his paint-pot, may come and mark the saplings intended to stand. I was told one telling fact. An old and good tenant applied to the steward for a couple of rabbits. *He sold him a couple, and gave a receipt for the money!* The tenant bought a handsome frame with glass front, and therein is displayed this bright specimen of landlordism. I was told that the tenants, as a class, were kept down; and although there were many good and liberal landlords, open to every improvement, yet there were "exceptions to the rule." How is agriculture to flourish under such auspices? Tenants are now becoming enterprising capitalists. Only let them the land upon proper terms: they, by their expenditure, will make it productive, and greatly to the advantage of landlord and tenant. This land of paddocks must be turned into fields. The tenant must graze sheep and cattle instead of rabbits and game, and that only for his landlord. "Property has its duties as well as its rights." I believe it is false economy. A good tenant would amply compensate a landlord in rent for destroying rabbits. I trust the visit of the Bath and West of England Society to this remote district will open the eyes of both landlords and tenants to their best and permanent interests. It is to a modern agriculture that England looks for her progress and prosperity; and landlords neglect their duty in withholding the requisite encouragements. Well, we are now in Devonshire: we leave Plymouth, and are again on "the line," and soon into a rich and well-cultivated country, the fields of fair size: the stock grazing are chiefly Devons, Shorthorns, and Leicester sheep. Have a view of Dartmoor to the left, over a beautiful valley. Now a high viaduct; deep valley very richly wooded; and a view of the sea to our right. The land rich and well-farmed at Wybridge. We noticed the beautiful establishment for making paper held by J. Allen & Sons. It is in a charming valley, crossed by a long viaduct. I again notice that these viaducts appear to be all upon timber supports. Dartmoor now close to us: it extends from hence across to Oakhampton. The country is very fine to our left, and we have a view of the sea to our right. We reach Kingsbridge-road. The country is still remarkably pretty; the fields very nice, but too small, and fences large, and trees overshadowing the land; the farming fairly done; the grazing stock, Devons and crosses of heavier-woolled sheep are seen. Near Brent we come upon the first water-meadows seen, and the fields near are much larger and much more like profitable farming. Herefords and Devons seen here, and notice large herds of dairy cows. Totnes: the country steep and abrupt, the soil on the red sandstone, or red-land. Note: Heard that the like custom, with regard to notices before plashing hedges, is customary in these parts of Devonshire. Newton: Near this station is a fine hill, covered with new houses, upon a dry red-land district; no doubt healthy for residents. We now approach the sea at Teignmouth, and from thence along the coast to Dawlish. The line of route by the sea, and along the marshes of the river, is very interesting. The marshes are good and extensive, but not equal to Romney Marsh. Exmouth stands immediately

opposite, as we leave the sea for the river side. Star-cross appears to be the home of many Exeter citizens, and is the station before reaching Exeter. We scarcely rested at Exeter; were soon in the country, which is very richly wooded. The land good red-land, and well farmed, and grazed chiefly with dairy cows and sheep, although but few of the latter are seen. The country along which we are now passing is very pretty to the Ottery-road station. There is a fine valley to the right, and the country is nicely undulating, and rich in woods; the fields much too small, and hedge-row timber very injurious, but rather better than some districts already passed. I have said very little about the crops thus far; in fact, we have not passed much arable culture, it being chiefly grazing and meadow; but the whole country appears in great freshness and beauty, having had plenty of rain, and the general report says it never looked better. We now pass Sidmouth to the right, down the valley, and enter a long cutting emerging upon a rich valley well grazed with Devons and Leicester sheep; the crops good and forward, evidencing no want of rain. Leaving the red-land we come to a district more of clay and stones, pass a very rich country on the left, but fields still far too small and sadly burthened with hedges and hedgerow timber: now a ridge of good high land, extending to the sea; through a cutting, to another charming valley, and rich to Honiton Station; again a very pretty country, overdone with wood and hedge, the grass in great plenty, the hills steep and abrupt; pass a broad valley to the left, hills to the right; the crops good and grass abundant; crops of beans seen, denoting a clayey district; enter a long tunnel; the cattle chiefly Devons, valley deep, hills like immense banks, and full of wood; no sheep seen; still small fields, and much wood. The whole country throughout for many miles appears as if it was laid out for ornamental scenery rather than profitable farming; the grass lands are not heavily stocked with cattle, and no sheep are seen; meadows plentiful. Coryton Junction: We are now passing through a region of dairy farms; much of the land is laid in as meadows; see many dairy cows, some very fine ones; a few Leicester sheep and Downs. Now in a sandstone district, the country very good, but small fields still, full of wood, and the lands not well-managed; much of the grass land under meadow. I would here remark that notwithstanding the large dairies around us, I have not seen a good modern farmstead along my whole route: nearly all are very homely, and thatched with straw, and not very extensive or commodious. Down sheep here, and a cross apparently of Herefords near. We come upon sheep-folds now—yes, and a creditable farmhouse, not thatched; but wood, wood, wood, and not much corn. Orchards now become prominent: a very pretty valley to our left, with more corn and fewer cows, but more sheep, chiefly Downs; some large flocks seen. The country varied—now red land, now clay, now red land, and well-farmed and properly grazed; a good farming near; a good dairy of cows, Shorthorns and Herefords. Pass Forde Abbey, a fine old place; mowing commenced near and making clover hay. We find more flocks, and large dairies of cows; the country a heavier soil, and fire-furrow lands; Italian rye-grass grown, beans cultivated. The dairies along this part of my route are large, varying from 40 to 70, or even 90 cows; nearly all of them are let out to dairymen at a stated price per cow. These dairymen undertake the sole management, and make their cheese and do all their business upon the farmer's premises. We now enter a portion of Somerset—Yeovil to Sherburne; very rich to our left. The Vale of Blackmore, which we soon reach, is a very fine agricultural district, and extensive; it is capital land—the arable is cleanly farmed, and the rich grass land is fairly grazed; the

tent under cereals, exclusive of wheat and oats (chiefly maize), and under tobacco. The whole acreage under wheat in all the Colonies is nearly 1,000,000 acres, whilst vines now cover 18,819 acres. The acreable yield of wheat, oats, and hay is highest in Victoria; New South Wales gives the highest acreable yield of maize and other cereals; the average yield of potatoes and tobacco is highest in Tasmania; and most wine per acre is made in South Australia.

Returns of the machines and implements in use upon farms and stations in Victoria, and of their value, are given: from these, it appears that 165 steam-engines, of an aggregate power equal to that of 1,239 horses, are used by farmers, and 23 steam-engines of 142-horse power by squatters. The total value of the plant or machines and implements possessed by farmers amounted to £804,515, whilst that in the possession of squatters is only valued at £61,182. The crops reaped and sown by machinery covered 160,649 acres, of which all but 1,100 acres were upon farms. The number of persons

employed upon farms is 42,211, and upon squatting stations 9,640.

There are 114 mills for grinding and dressing grain in the colony; 106 of these are worked by steam and 8 by water power. The amount of horse-power employed is 2,952. There are 355 pairs of stones at work, and the quantity of grain operated on was 4,000,000 bushels. The flour made during the year was 85,586 tons. The approximate value of the machinery and plant of the flour-mills was £176,425. There are now 86 breweries in the Colony, employing 648 hands and 471 horses. Nearly 9 million gallons of beer are made, in the manufacture of which 539,000 bushels of malt, 603,289 lbs. of hops, and 6,290,000 lbs. of sugar are used.

In closing this summary, it may be added that as there are stated to be officially 43½ million acres of land available for agricultural or pastoral purposes in the colony and as not 8 million are yet occupied, there is ample room for expansion of population and stock, even at the rapid rate at which they have been shown to be increasing.

## THE MISMANAGEMENT OF LANDED PROPERTY.

The following account, extracted from a local newspaper of the district in which the estates are situated, gives an account of changes made and about to be made on the Saverlake estate—a very extensive property in Wiltshire, belonging (so far as an entailed estate can belong) to the Marquis of Ailesbury. The estate is chiefly on the chalk formation, some part of it extending to the green sand and marl formations respectively, cropping out below the chalk. Part of the high lands are poor and thin clay above the chalk; the greater portion consists of thin soil upon chalk, which under high cultivation may be made largely productive, and carries sheep well, while the lands on the green sand and marl are naturally fertile, but require skilful management. This is particularly the case with the marl soil. By far the greater part of the estate consists of poor or light land; there are very large woods on the property, and Saverlake Forest is an enormous tract of uncultivated land, stocked with fallow deer and game, in which the tenants of many of the adjoining farms have the liberty of turning in some of their stock during the summer half of the year. A "run in the forest" is, however, only available for stock of a third or fourth class character, as the natural growth of the soil is not sufficiently fertile to carry anything like good stock. It may form a tolerable summer's run for sheep during the day, but, practically, the deer and game consume nine-tenths of such natural produce as there is. The terms said by the *Marlborough Times* to have been recently imposed on the tenants would seem to be about as complete examples of the mismanagement to which estates in England are subjected as could well be brought together: "THE SAVERLAKE ESTATES: Very important changes are about to take place in the relative position of landlord and tenant on the Marquis of Ailesbury's estate, consequent on the late revaluation of the whole of his lordship's property, which has been made by Mr. Carey, of Shrewsbury, on the accession of Mr. Bolam to the stewardship. Not only has the rental been, in most cases, increased, and in all re-adjusted in accordance with the valuation, but the terms of holding have been considerably altered. Day by day, during the past week, by request of the steward, the farm tenants have attended at the Saverlake Forest Office, to receive the new proposals and future terms of holding. These, with the re-adjusted rent, are to be acceded to before Lady-day next; but we are sorry to hear that the increase of rent has in many cases given great dissatisfaction, and that the future rental-change is pronounced to be excessive. The rent of some farms has been raised upwards of 35 per cent.; in one instance we are informed the rent of 130 acres has been increased by £80 or £70 a-year, and another tenant has to pay about £200 additional rent per annum. The agreement varies in many respects from the former terms. Provision has been made for quarterly payments of rent—instead of half-yearly—and for twelve months' notice to quit to be given on either side. The

agreement also reserves to the landlord all game and rabbits. The tenant is to keep the buildings in good repair; to pay one-half the cost of labour for landlord's repairs, and one-third the cost for outside painting. All the 'hay, straw, haulm, fodder, clover, tares, artificial grasses, cabbages, root crops, and other produce' are to be consumed and converted into good manure, and to be used on the land. Then there are some additional regulations as to cropping, and the 14th clause, which must surely be equivalent to additional rent, provides that the tenant keep insured to a fixed sum, in the name and for the benefit of the landlord, all farm buildings against loss by fire, in an office approved by the landlord, and to produce, when required, the policy of insurance, and receipts for the current year's premium. The occupiers of house property—particularly in Marlborough—must also be prepared for a considerable increase of rent, if we may judge from the exalted ideas we know to have been entertained of the property by Mr. Carey. It is to be hoped, however, that Mr. Carey has not based his calculations on the relative value of house property in his own county town of Shrewsbury. The trade now done, and for many years past doing, in Marlborough, will not warrant any increase of rent, nor can a grave reduction in the income of the agriculturist be made without being proportionately felt in the town." An increase of rent to such an extent as is mentioned could only be justified by giving to the tenants at the same time additional security and length of tenure; but it would seem that, besides advance of rents, new restrictions and burdens are imposed on the tenants. They appear to have held, hitherto, simply as yearly tenants, governed only by the custom of the country. This is perhaps, the least satisfactory form of a yearly holding. If there be a reasonable confidence between the tenants and the landlord—or perhaps we should say the steward—husbandry may be carried on in a moderately good manner, though it is not likely to make any striking advance. But when that simple—homely—system is departed from, and the yearly tenant is required to sign a written agreement containing an elaborate system of restrictions, game reservation, cropping, manure, and crop-consuming clauses, such as are indicated by the foregoing extract, a new system of petty and vexatious interference is inaugurated, which must soon drive from the property all the best farmers, and will assuredly deteriorate the cultivation. There is, perhaps, no greater mistake than to bring a surveyor from a different district to re-value an estate, especially when it is intended to lessen the free action of the tenants.—*The Economist*.

WORTH KNOWING.—It may not be generally known that Indian corn given whole to horses, is a very dangerous feed. I have seen two cases, one a very narrow escape from death through inflammation, brought on by this feed; the other resulted in death in a very short time this week. It swells the stomach, and is bad to digest.—R. R.

## ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.

At the annual meeting on Wednesday, June 17, the following report was read and adopted.

Premising that the year ending the 31st of December, 1867, was fraught with a larger amount of commercial stagnation and social disorganization than any which had preceded it within their recollection, the Council have just reason for self-congratulation in the well-assured fact that the Royal Agricultural Benevolent Institution, whose affairs they have the honour to direct, has not in any degree retrograded from that sphere of expansion which for eight successive years it has been gradually developing. Whatever might be thought in quarters where the "utilizing" principle is advocated, in exclusion of all prospective considerations, the Council are unanimous in thinking that too high a value cannot be set on that wise forethought which has directed, year by year, the investment of capital, not only as a means of imparting strength and efficiency to the Society, but as a guarantee for the punctual fulfilment of any engagements to which the Council, in the execution of the trust confided to them, might hereafter find themselves pledged. Pensions for life, once granted, cannot be revoked without manifest injury and injustice to the recipients. Having moreover due regard to the importance of creating new and enlarged sources of relief, the Council are strong in this conviction—a conviction based upon eight years' practical experience—that the course which has been pursued is the safest and the best for all the practical purposes for which this charity was called into existence by its excellent founder. The Institution now stands on a solid foundation, and may take a foremost place amongst those which adorn and dignify this country. During the past year fifteen pensioners have been placed on the books of the Institution, making up the total number since the first election to one hundred and six. The financial position

of the Institution is not less gratifying. The donations and subscriptions amounted to £4,860 17s. 11d., being £969 13s. 2d. in excess of the previous year. In addition to the balance of £621 9s. 4d., £507 10s. have been received from dividends, making the total receipts of the year £5,979 0s. 6d., of which £1,475 have been paid to pensioners, and £2,768 15s. have been added to invested capital of the institution, leaving a credit balance at the bankers, after payment of all expenses, of £760 8s. 8d.

Messrs. Johnson, Naish, Hudson, and Brown, retiring members of the Council, were re-elected, and Messrs. Beddell, Baldwin, and Donald Nicoll were elected in the room of Messrs. Pain, Rigden, and Sanday, who also retired by rotation. After some other formal proceedings, the Council proceeded to the election of pensioners. The following are the names of the successful candidates: Male pensioners at £26 per annum—Edmund Painter, John Steel, Thomas Barnett, David Unthank, William Turvill, Charles Theedam, Josiah Jerrard, and William Pingley. Married pensioners at £40 per annum—Walter and Hannah Mansfield, Thomas and Hannah Hughes, and William and Anderson Des Forges. Female pensioners at £30 per annum—Elizabeth Sandon, Jane Hulls, Ann Harris, Ann Carter, Sarah Wheeler, Elizabeth Clarence, Sarah Brett, Mary Needham Brett, Arundell King, Jane Haviland, Rebecca Davie, and Eliza Jones. The following orphan children were also admitted: Andrew Anascomb, Earl Spencer, Thom Giddings, Edward M. Stanford, Annie Gearing, Louisa C. Grant, Elizabeth Back, Ann C. Fell, Ann Eliza Adams, Elizabeth Belliss, Sarah Polley, Kate Spencer, and Mary E. Hall.

The thanks of the meeting were voted to Viscount Enfield, M.P., for his kindness in presiding at the anniversary of the Institution, and to Mr. Shaw, the Secretary.

## STAFFORDSHIRE CHAMBER OF AGRICULTURE.

A meeting of this Chamber was held on Saturday, June 13, at Stafford; Mr. R. H. Masfen presided, and there were about twenty members present. The first business on the circular convening the meeting was as to "the appointment of well-informed witnesses to give evidence before the House of Commons Select Committee upon the disadvantages of the present system of county finance, and as to the best machinery for establishing a representative control of the expenditure."

The CHAIRMAN said he was rather at a loss to know whom to nominate to represent them on such a question.

Mr. J. NEVILLE (Haselour) said that so far as this county was concerned they had reason to be satisfied, the financial board being composed of thorough business men who would not allow any unnecessary expenditure of the funds over which they had control. But there were many counties which were not so well represented, and the funds of which were not so well managed; and as the principle propounded was a good one, that Chamber ought to assist in obtaining such a measure as was thought desirable to improve the working of the present system.

Mr. MAY expressed a similar opinion. Though he did not think there was any unnecessary or wasteful expenditure of the finances of this county, he considered that they ought to be ready to assist others who were not so favourably circumstanced. He suggested that they should request Mr. Startin, of Exhall, near Coventry, to give evidence before the committee. Mr. Startin was a gentleman well-acquainted with financial matters, and a short time ago he read a very excellent paper on "The Rating Question" at the meeting of the Midland Farmers' Club, at Birmingham. Very probably Mr. Startin might be nominated by the Warwickshire Chamber, but even if he was it would be strengthening his hands if nominated to represent this Chamber as well.

The CHAIRMAN referred with disapprobation to the course

which he said had been taken by the magistrates with reference to the dissolution of the Burton Highway District. When the ratepayers petitioned the magistrates to allow the district to be dissolved, the magistrates would not listen to them. The subject was brought forward a second time, and with a similar result, although no magistrate in the Burton district would second Mr. Bass's amendment in opposition to Mr. Lyon's motion.

Mr. MAY said the Chairman was in error. The magistrates at the last Quarter Sessions granted, by a majority of 21 to 10, a provisional order, which was all they could do.

Mr. May's suggestion was agreed to, and the Secretary was instructed to write to Mr. Startin to know whether he would consent to represent the Chamber.

The next business on the programme was to appoint a maltster, brewer, or other person of the consuming interest, to give evidence in favour of the repeal or transference of the malt duty.

Mr. MAY remarked that they should endeavour to select some gentleman who was not only practically acquainted with the subject, but who, being in an extensive way of business, would carry some weight and influence with him in whatever evidence he might give. It was pretty evident that the Government would not sacrifice the revenue arising from the tax altogether, amounting as it did to six millions annually, and he thought the aim of the committee would be to transfer the tax from malt to beer. They wanted some one, therefore, who would give evidence favourable to such a transfer, and he did not imagine that the brewers as a class were so favourable.

Mr. NEVILLE said they were decidedly unfavourable.

The names of several gentlemen were mentioned, and amongst the rest that of Mr. M. T. Bass, but at the same time an opinion was expressed that he would be opposed to the transfer of the tax from malt to beer. It was decided that

the Secretary should write to Mr. Bass and inquire what his views were on the matter, and that in case they were favourable he should be asked to give evidence.

Attention was next called to a public meeting proposed to be held at Leicester, on the Friday of the show week, of the members as of the various chambers of agriculture, one of the subjects for discussion being, "The Pressure of Local Taxation upon Real Property."

The CHAIRMAN and Mr. PERRY said the subject referred to was the great question of the day, so far as the agricultural interest was concerned.

Mr. NEVILLE hoped that at the meeting referred to the question would be taken up in an earnest manner, for one expense after another was being thrown upon the rates, and there was only one species of property that could bear the burden.

## FOREIGN AGRICULTURAL GOSSIP.

The Hohenheim Agricultural Institute in Wurtemberg has just celebrated the fiftieth anniversary of its foundation. Herr von Goether presided over this celebration, which collected an imposing number of old pupils of the Academy, among whom were 202 Wurtembergers, 10 from North Germany, 7 Austrians, 5 Bavarians, 4 Swiss, 1 Russian, 7 from Baden, and 2 representatives of the new world. After the songs, without which no *fête* would be complete in Germany, and after the customary speeches and felicitations, when the pupils had welcomed those who had preceded them in their career, and when the company assembled had visited the workshops and collections, the sound of a gong gave the signal for a *déjeuner*, which was served on the terrace before the château. Neither the King nor the Academy of Hohenheim nor its director Herr von Werner was forgotten in the toasts which terminated the repast; and Herr von Goether was not the least applauded of the orators when he assured the joyous meeting that all plans for the extension and improvement of the old and celebrated institute would meet at his hands, as a minister, with a reception all the more sympathetic, as he was sure beforehand of the agreement and good-will of the King. This good-will was, indeed, proved by the presence of his Majesty, who, accompanied by the Queen, arrived subsequently, and caused to be presented to him some of the foreigners who "assisted" at the interesting agricultural jubilee, and then proceeded to the trial field, where a reaping machine and other apparatus were tried before him. This unexpected visit was greeted with enthusiasm by those present, who saluted the royal couple with much applause, since they saw in this act of good taste a proof of direct interest and effective solicitude for the first and most ancient establishment devoted to agricultural instruction in Germany.—By a contrast which has excited regret among French agriculturists, the Grignon school has not been able to celebrate its fortieth anniversary in so striking a manner; and notwithstanding the splendour of its past, its slow re-organization for the future and its half existence in the present are subjects of grief among those devoted to the progress of agriculture.—In Bohemia, questions relating to the organization of exhibitions and agricultural instruction are exciting but little interest at present, the whole attention of proprietors and farmers being directed to the cultivation of beet-root and to manufactories of indigenous sugar, which, according to a local expression, come up literally like mushrooms. In some localities where habitations made themselves remarked neither by their number nor by their importance, and where cultivation might even pass as negligent, persons travelling are now much surprised to perceive fields of beet-root of a very fine appearance and great works, the high chimneys of which command general attention. These results are due in great part to the development of the spirit of association, as the majority of these enterprises are constituted by shares, and among the principal persons interested are landed proprietors, who have undertaken at the same time to devote a certain portion of their land to the cultivation of beet-root. It was important also to assure the co-operation of small cultivators, and with this object associated manufacturers have concluded with such persons contracts which, for the season of 1868, fix the price of beet-root delivered at the works at 1s. 3d. per cwt., roots from marshy lands being excluded. This fixed price assures the producer from all eventualities; but it is further stipulated that in case, in the months of October, November, and December, the price of mixed sugar should be quoted on the Prague market above 30 fl., the sum paid to cultivators shall be slightly increased. But manufacturers do not content themselves with associating

cultivators, to some extent, with them in their profits: they also make advances to them of money, without interest, in proportion to the quantity of land cultivated with beet-root: these advances are made to the extent of £3 10s. per acre. The refuse left from the beet-root after treatment is also supplied to cultivators for manurial purposes, the charge made being deducted from the price paid for the raw material delivered. Finally, transport indemnities, calculated according to the distance of farms from manufactories, are granted to producers. These indemnities are payable in money or in refuse at the pleasure of those entitled to them. These are advantages which deserve to be taken into serious consideration; but some persons look back and affect to regret the time when the proprietors of large farms sold their beetroot on better terms than at present. But, if the present state of things is not so good for some, it presents an improvement for the majority; and it cannot be doubted that sugar-producing industry has become a real source of prosperity for the agriculture of Bohemia.—June is the month for the meetings and exhibitions of French agricultural commissions, and at all the meetings lately held the new Society of Agriculturists of France has evoked sympathetic adhesions. "Instruct yourselves; make an interchange of your ideas," said the Viscomte Cormedet to the Chénérailles Committee; "there is the principal advantage of meetings like ours—in seeing, you learn to do better; in meeting each other, you can take concert with each other—and thus the wants and aspirations of agriculture can be declared, expressed, and summed up. Moved by this thought, a certain number of eminent agriculturists—some of whom honour me with their friendship—have sought to found at Paris a vast association, which forms French agriculturists into a living and compact body. Your president—whom I applaud on finding him here in his old place—and myself have been among the first to welcome an idea which seems to us likely to be attended with fruitful results, and which now comprises nearly 1,200 adherents. Under the presidency of one of our statesmen, who disdains not in his leisure hours to occupy himself with agriculture—I mean M. Drouyn de Lhuys—this vast society, divided into several sections, will assemble every year at Paris, in order to discuss the interests of agriculture, and to affirm and defend them if necessary. This will be, in fact, a Parliament for our agriculturists." At a meeting of the Château Thierry Committee, the president, M. de Tillancourt, deputy to the *Corps Législatif*, spoke to the same effect. A special exhibition of mowing and reaping machines, held by the Meaux Committee, was also an occasion for bidding welcome to the new association. We should note, in passing, that the jury of the Meaux competition awarded the first prize to the mowing machine of M. Lallier; that of Wood, exhibited by M. Peltier, less fortunate than at Senlis, was classed in the second rank. A machine of smaller dimensions, on Wood's system, modified by M. Peltier, worked separately. The jury was very well satisfied with its manner of working, and awarded it a first prize of £16.—The annual exhibition of the Committee of the Seine-et-Oise was held on the lands of the farm of St. Germain-les-Corbeil, belonging to M. Darblay, jeune, and cultivated by M. Renard. The committee more than fulfilled its programme by organizing a very fine horticultural exhibition, and instituting steam ploughing trials, which proved perfectly successful. One of Fowler's apparatus, belonging to M. Decanville, of Petit-Bourg, was worked during the day. On the report of M. Lucien Rousseau, of Angerville—who did not allow the occasion to escape him of rendering homage to the idea which originated the Society of Agriculturists of

France—the prize of honour of the committee was awarded to M. Duclos, of Marolles-en-Brie. A banquet of 600 covers terminated the *fête*. Toasts were proposed—by M. Darblay, to the Emperor; by M. Boelli, Prefect of the Seine-et-Oise, to Agriculture; and by M. Féray, of Essonnes, to Agricultural Associations. All these toasts were warmly applauded; but what took the fancy of the meeting most was a humorous and forcible, although hastily-improvised, speech of M. Victor Borie, editor in chief of the “*Echo Agricole*.” “I do not wish,” said M. Borie, “to raise complaints against any one; it has been the same from all time and under all Governments, but it is a fact of which Agriculture is not proud, that while our war budget is £16,000,000 our agricultural budget is but £160,000. Some days since there assembled at Paris a body

composed of honourable men, belonging to all religious beliefs and all opinions: this was the Peace League. The members of this Peace League are very brave men, who have the goodness to believe that you can make men very happy without shooting them. Well, I think like them, and we all think like them. What is the Agricultural Committee of the Seine-et-Oise but a league of peace and a league against misery and famine? And what is this new Society of Agriculturists of France, of which we have heard, but a league of all agriculturists to render the soil fruitful and combat misery and famine? . . . Make roads; they are a veritable encouragement of Agriculture. Found some cannons the less, and make roads; manufacture some chassapots the less, and make roads—roads, and still roads.”

## CALENDAR OF AGRICULTURE.

Finish the sowing of turnips, as directed last month. In the eastern counties, turnips sown in in this month escape the fly better than in June, the insect being not so prevalent as in the former month, and the plants are less liable to be mildewed. Horse and hand-hoe potatoes, mangold wurzel, and the earliest sown Swedish turnips. Those plants growing on lands with stiff under-soils are best ploughed in the intervals of the drills by the miniature plough of wood or iron. The narrow-pointed share with one wing pierces the subsoil more effectually than the duck-footed share, raises fresh soil to be scarified by the light implement with two knives, with the power of one horse for both operations. The hand-hoeings are done betwixt the scuffings, loosening the soil between the plants, and cutting all weeds that escape the ploughings. The single plough requires more time than the double-knived scufflers; but the work is better performed; and true economy consists not in getting things cheaply done, but in getting them well done. The processes are repeated till no weeds appear, and the land is completely fallowed, with nothing growing on it except what is sown or planted for crops, exhibiting a true specimen of the cultivation of land. The young plants derive much benefit from the frequent stirrings of the intervals of the drills, and most in dry weather: it causes evaporation of moisture, which is imbibed by the leaves. Tall weeds are pulled by hand, if any rise after last scuffing and hoeing.

Clay fallows for wheat are prepared by ploughing, harrowing, and rolling; and after each earth of cultivation the weeds and stones are picked by hand and removed from the ground. The dung and lime intended to be applied to the land are prepared and brought forward.

Draining of wet lands is done with the greatest neatness and cleanliness on a surface of grass, as the turf is present to cover the stones or tiles, and the surface is not puddled as on arable lands in wet weather. The proper direction of the drains must be marked out in winter, when every wetness shows itself. The drains may be dug to the required depth beforehand, and the bottoms only to be cleaned when the cavities are filled, the turf inverted on the materials, and the excavated earth replaced in the drain. On fallow lands the drains must be excavated, filled with the stones or tiles, the covering

laid on these materials, and the loose soil placed over all, with much force, not to impede the working of the land.

Wean the latest lambs, and place them on the best pastures. Put mares to the stallion regularly.

Attend that the pasture fields have a supply of water, and that no gaps are continued in the fences of the fields, and that no dilapidated or awkward moving gates are seen to mark a slovenly management and a careless profession.

The sheep flocks will require attention. Protect by the contents of the dredging box the deposit of the eggs of the maggot-fly on the body of the animals. Dress clean the posterior parts of the animal from the adhesions of the excrements.

The corners of all pasture fields, both natural and artificial, which includes the whole farm, are very usefully widely planted with trees of spreading branches, as beech, ash, and sycamore, to afford shelter to cattle and sheep from heavy rains and scorching heats, and coolness in hot seasons. In arable lands, the corners of plantations may be extended to a circle, which the plough go round without turning at the corners, and thus relieve an inconvenience. Shelter-sheds for cattle may be placed in the subdivision fences, with a roof sloping into each, with a central height of 15 feet, a front height of 6 or 7 feet, and a bottom width of 12 or 14 feet. Permanent pastures should have these provisions as a necessary furniture. Sheep are much benefited by small thatched cots in the corners of the fields, 5 or 6 feet in the central height, 4 feet in front, and about 5 feet wide. These provisions are very useful in any localities of a high or low elevation.

Hay harvest will be general during this month. Dry the herbage in two or three days, by alternate tedding and cocking; build it into long stacks, lay it lightly together, and allow it to settle by its own weight. It is a mistake to tread the herbage firmly together. Pull nothing from the sides of the ricks till well settled; then dress it into any form, and thatch it without delay. A scaffold of boards is raised to pitch the hay to a high rick. When the hay is damaged by rains, mix salt in the rick, as directed last month. A tarpaulin cloth will cover the stack from rains, when the building is interrupted, and removed in dry intervals to allow the escape of the gaseous evaporations. A light sail-cloth will defend day showers, suspended from a

rope passing along the rick, fastened to an upright pole at each end, and raised and lowered by pulleys.

Corn harvest will commence this month in early localities with the most forward grains. Early peas, barley, and rye will be cut first. Tie the barley and rye into sheaves, to be placed in shocks of twelve together; lay the peas in small heaps, and turn them frequently. Carry the grains quickly when dry, to be lodged in barns in a clean readiness, or built into ricks on stands of stone ready in position, or on the ground with straw spread beneath.

Vetches are now the green food of the farm. Cut the herbage fresh in the forenoon for daily use, for maintaining the work-horses, the milch cows in the yards and sheds in the evening feed; the sheep consuming the crop on the ground, or cut into

troughs along with oats and cake for being fattened. This most valuable plant admits a large application in affording a most nutritious green food to all the animals of the farm—horses, cattle, sheep, and swine, and in acting as a smothering crop on the land, covering the surface, killing all weeds, and in mellowing the surface of the ground into a moist and clammy state of fertility. The crop must be thick on the ground, from thick-sowing of seed, and a careful heavy rolling of the land in the young condition of the plants, in order to lock with a key the moisture that is in the ground and what may fall from the heavens for future use. The vetch in the winter and spring varieties form the green food of the farm for four months of the year, and demand a much larger attention than has been yet bestowed.

## CALENDAR OF GARDENING.

### KITCHEN GARDEN.

Sow peas of any short kinds in the earliest days of the month, and again soon after: the crop may be fine, and therefore acceptable in September. Sow endive twice in the month, from the 8th to 12th, and from 20th to 25th. Plant kidney beans, French beans, and scarlet runners; round-leaved spinach early, and the winter, or prickly sort, in the latter end of the month. Sow lettuce, radish, and a large succession of turnips in the red and white varieties; early Dutch, white, and yellow, to come in late in the year and through winter.

After the second week, sow cabbage seeds, York and Varack, for coleworts, called "greens," one of the sweetest of spring vegetables; and at the close of the month, in some situations, for early hearting spring cabbages. Sow small saladings as may be required, as carrots and onions, to be drawn young, and, on peorish land, a few of the large bulbous to stand the winter, and subsequently to be transplanted for an autumn crop.

Transplant celery, the last crop: it must be carefully earthed up; and in doing this for the first and second times, hold each plant compactly with one hand, while the other applies fine earth close around the lower part of the leaves, but not so high as the growing heart. Give water copiously along the trenches, if the weather be dry, for the first good stand is most important.

Transplant broccoli at various times for early and later spring supply, choosing, if possible, a moist state of soil; otherwise, if the weather be dry, every hole must be filled with water. The ground should be rich in nitrogenous manure; and therefore some soot, mixed up with spit dung, would be useful, as it contains salts of ammonia. May-sown cauliflower may be treated in the same manner.

Transplant leeks; dig and manure richly a plot for a row or two, and use with the dung 2 oz. of sulphate of ammonia to the small barrow. Very prime guano, to the extent of a pint to the same bulk, would comprise phosphates of ammonia and of lime, several ammoniacal and nitrogenous compounds, common salt, and neutral sulphate to the soil. It is the comprehensiveness of pure guano

which stamps its value, and therefore it should always be added to the less powerful manures as a restorative. In planting leeks, make deep case-like holes, and drop therein, applying water in a small stream, so as to fix the roots of each.

Transplant vegetable-marrow and cucumbers already raised in heat. Dig a hole for each in a warm open spot of ground; put in a barrow or more of leafy, rich manure, and cover it with some light rich soil; plant, water, and cover with hand-glasses till growth be established, and then gradually train out the runners. Stop the points occasionally to obtain laterals.

Propagate herbs by slips. Collect camomile flowers.

At all seasons, and under most circumstances, while crops are growing, the following are required to be done: Stick and top peas, also kidney and broad beans; earth-up legumes and potatoes; peg down and train the regular advancing shoots of vegetable-marrow, gourds, and cucumbers; hoe and move the surface among crops; give weak guano-water to plants of the cabbage family. These directions are not many, nor any way expensive.

### FRUIT DEPARTMENT.

In the end of the month, plum and cherry-trees may be trained in the best placed shoots; apple and pear-trees next month. Budding is now performed with wall-fruit, and will succeed if done adroitly, by always recollecting that both stock and scion be in a moist condition, when the bark detaches freely from the wood. Success depends upon attraction between the vital organizable juicy membrane, which exudes, or is deposited between the yearling wood and the inner bark. The bark must rise freely, owing to the exudation of the proper juice between the new wood and the bark. If the operation be timely and skilfully performed, the fluids attract each other, solidify, and cause a union between the secreting surfaces. The art may be learned by watching the operations of a jobbing gardener or workman, which are found in most country places, and are occasionally employed by farmers of the higher grade to perform the upper

works of the garden. To these persons the above directions can only apply.

Lay strawberries at the first joint into small pots of free loam. They will root speedily in moist weather, or if watered when dry.

#### FLOWER GARDEN.

Roses are budded by the rules that have been given for fruit-trees. The largest plants must be chosen in health and strength, and which are judged, from appearance, to contain the juices in abundance. Experience will soon enable to judge these appearances, and also perform the dissection with skill and utility. It is a very pleasing and instructive employment.

Keep all parterres, flower borders, lawns, walks, and shrubberies in neat order, free from weeds, and duly regulated.

The collection of manure for the kitchen garden claims a chief attention, as no articles need be imported as auxiliaries, guano-water being only recommended for some broad-leaved plants. All

lands in farm or garden cultivation should maintain its own fertility—light lands of sands, downs, and commons excepted—for green food and sheep food. The garden requires a liquid pit of brick and cement, to contain every vegetable and earthy refuse, cattle droppings, and all large weeds cut into short lengths, saturated with the soapy waters and urinary liquids of the dwelling-houses, all carefully preserved for the special purpose. A dry compost-heap may be added of lime and all earthy bodies, to make a change of manure. The water-closets to hold the excrements in box on wheels, to roll backwards into an uncovered position, in which to receive fine earths as a mixture, to absorb the moisture, and kill the odour, and from which the contents are lifted for use. One or two common privies will collect on the largest farms, the farm dwelling being always separate. These three sources will supply most amply every demand for manure, all gathered on the farm, at little expense, and not by any extra trouble or interference.

## AGRICULTURAL REPORTS.

### GENERAL AGRICULTURAL REPORT FOR JUNE.

In the early part of the month, a severe drought was experienced throughout the country. It enabled the hay-makers to complete their operations at an early period; but it completely parched up the crops in many districts. The wheats upon light soils have suffered to some extent, and it is anticipated that their yield will fall short of previous expectations. Upon strong lands, however, very little damage has been sustained. It is hoped, therefore, that the entire crop will come up to a fair average. The barley and oat crops will, we apprehend, fall short of last season, owing to the want of an adequate supply of moisture. Beans and peas, however, are likely to yield well.

Owing, chiefly, to the rapidly diminishing stocks held by our farmers, very small supplies of English wheat have been brought forward during the month. The millers have, therefore, been compelled to pay an advance of 2s. per qr. from the lowest point, and very little disposition has been shown to force sales by the importing houses. As far as we can judge, the value of both English and foreign wheat will be supported for several months. The sale for barley and oats has been very inactive, on easier terms, and at Mark Lane the top price of flour has fallen 4s., or to 60s. per 280 lb. We have very little change to notice in the value of either beans or peas: for the most part, sales have been wholly in retail.

In the forward districts, nearly the whole of the crop of hay has been secured in very fine condition. The quantity, however, is considerably less than last year; but there is every prospect of a heavy second crop. In the metropolitan markets new meadow hay has sold at from 36s. to 80s., old 70s. to 95s., clover 70s. to 110s., and straw 30s. to 36s. per load.

The reports from the plantations, in reference to the appearance of the hop bine, are favourable. For the most part, fly is scarce, and the burr promises well; indeed, it is supposed that the crop will be unusually large and of fine quality. On the continent the bine looks remarkably well. The sale for hops in the Borough has been much restricted, and the quotations have had a drooping tendency.

The scanty supply of moisture has retarded the progress of the potato crop. Very few complaints respecting disease have reached us, and most of our correspondents agree in stating that there is every prospect of a large growth. Very few old potatoes have been brought forward; but new qualities have sold at from 6s. to 12s. per cwt.

The colonial wool sales held in London have been brought to a conclusion at one time, owing to the large quantities of wool taken by continental houses; prices showed an advance of  $\frac{1}{4}$ d. to  $1\frac{1}{4}$ d. per lb., compared with the March sales; but, prior to the close, that improvement was lost. Considering that over 200,000 bales were brought forward, it is surprising that the quotations were so well supported.

The drought has had a most prejudicial effect upon the beet and turnip crops. In some counties they are partly destroyed, and it is believed that even the late fine showers will not improve them to any extent.

There has been a moderate demand for most kinds of produce in the Scotch markets, and prices generally have been well supported. The country has suffered much from the late dry weather.

Very small supplies of wheat have been exhibited in the Irish markets. The demand has fallen off; yet prices have been well supported. The island has been visited with copious showers of rain, which have greatly improved the appearance of vegetation.

# REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Owing to the serious drought experienced in the early part of the month, the supply of food in the pastures has fallen off considerably. Many of the graziers have, therefore, been compelled to withdraw their stock, and the consumption of food has fallen partly upon hay. This has led to an increased supply of beasts in our leading markets, and to much inactivity in the demand for most breeds. The fluctuations in prices have as a consequence been somewhat extensive. At one period, the best Scots and crosses sold at 4s. 8d.; but, owing to the limited quantities of dead meat on sale in Newgate and Leadenhall, the quotation has since advanced to 5s. per 8lbs.

The numbers of sheep brought forward have been extensive; but we have observed a falling off in their general weight and condition. Although a good business has been doing, the rates have fluctuated. The best Downs and half-breeds have ranged from 4s. 8d. to 5s. per 8lbs.

Lambs have come freely to hand. The demand has fallen off, and the leading quotations have been 5s. 6d. to 6s. 6d. per 8 lbs.

We have very little change to notice in the value of calves. Prices may be quoted at from 3s. 8d. to 5s. 2d. per 8 lbs. Fair average numbers have been brought forward.

The best small pigs have supported previous rates, with a fair demand; but inferior pigs have sold heavily. The former have changed hands at from 3s. 10d. to 4s. 4d., the latter 3s. 4d. to 3s. 8d. per 8 lbs.

The following figures show the total supplies of stock exhibited in the Metropolitan Cattle Market during the month:—

	Head.
Beasts ... ..	18,650
Sheep and Lambs ... ..	177,690
Calves ... ..	2,875
Pigs ... ..	1,480

## COMPARISON OF SUPPLIES.

	Beasts.	Cows.	Sheep and Lambs.	Calves.	Pigs.
June, 1864 .....	25,890	550	138,460	2,786	3,280
1865 .....	24,050	646	165,720	4,278	3,210
1866 .....	18,820	130	139,880	1,864	1,782
1867 .....	16,270	120	146,660	2,600	2,048

The comparison of the arrivals of English, Scotch, and Irish beasts is as under:—

From—	June, 1866.	June, 1867.	June, 1868.
Norfolk, Suffolk, &c. . .	9,000	5,570	9,000
Lincolnshire .....	—	400	370
Other parts of England.	1,930	2,240	1,920
Scotland .....	59	737	97
Ireland .....	20	20	220

The imports of foreign stock into London were as follows:—

	Head.
Beasts ... ..	5,327
Sheep and Lambs ... ..	16,849
Calves ... ..	1,910
Pigs ... ..	569
Total ... ..	24,655
Total in June, 1867 ... ..	48,508
" 1866 ... ..	47,425
" 1865 ... ..	61,935
" 1864 ... ..	38,020
" 1863 ... ..	30,059
" 1862 ... ..	22,841
" 1861 ... ..	32,751

From the above comparison it will be seen that the imports of foreign stock are falling off considerably, notwithstanding that prices continue remunerative. We learn, however, that on many parts of the continent both beasts and sheep are higher in price than in England. Whilst high quotations continue abroad, we can hardly anticipate any important increase in the importations.

Beef has sold at from 3s. to 5s.; mutton, 3s. to 5s.; lamb, 5s. 6d. to 6s. 6d.; veal, 3s. 8d. to 5s. 2d.; pork, 3s. 4d. to 4s. 2d. per 8 lbs. to sink the offal.

## COMPARISON OF PRICES.

	June, 1864.	June, 1865.
Beef from .....	s. d. s. d. ... 3 4 to 5 0	s. d. s. d. ... 3 6 to 5 2
Mutton .....	3 6 5 2 ...	4 4 6 4
Lamb .....	6 0 7 0 ...	6 0 7 8
Veal .....	4 0 5 0 ...	4 0 5 4
Pork .....	3 6 4 0 ...	3 6 4 10
	June, 1866.	June, 1867.
Beef from .....	s. d. s. d. ... 3 10 to 6 0	s. d. s. d. ... 3 4 to 5 6
Mutton .....	4 0 6 0 ...	3 8 5 4
Lamb .....	6 8 8 0 ...	6 0 7 0
Veal .....	5 4 6 4 ...	4 0 5 6
Pork .....	4 0 5 2 ...	3 4 4 6

Scarcely any foreign meat has been on sale in Newgate and Leadenhall; and the arrivals from Scotland and various parts of England have been on a limited scale. On the whole the trade has ruled steady. The leading quotations have been as follows:—Beef, from 3s. to 4s. 6d.; mutton, 3s. 2d. to 4s. 8d.; lamb, 4s. 6d. to 5s. 4d.; veal, 3s. 6d. to 4s. 6d.; and pork, 3s. to 4s. 6d. per 8 lbs. by the carcase.

## WEST SUSSEX.

The state of the growing cereal crops is now a matter of vast interest and importance. I see there are persons as last year who are telling the public of the grand appearance of the crops generally, but I think these will turn out as last year to be false prophets. In this division of the county, which has such variety of soils, my report must have reference to locality. On the good land of the sea-coast I think the wheat crop is generally looking well, and with favourable weather will produce a fair average yield. On the hills, except some pieces which have been thin of plant all the winter, from the ravages of slug and wireworm, I believe the prospects are good. In the stiff land of the Weald I do not think appearances are in favour of an average. It is a question also whether on all soils the present unexampled weather (for the sun shines from morning till night) will not injure the crop, and bring on premature ripeness. I know old farmers say "nothing like dry weather for wheat." I say so too, but this is rather beyond ordinary dry weather, and in addition we have now a parching east wind. Barley and oats, except on the very best soils and where got in very early, must, I think, be short in straw and deficient in yield. In the clay lands of the Weald a large proportion of the oat crop will be a failure. All root crops must suffer from the present dry weather. Mangold wurzel came up badly, and swede turnips may be considered hitherto a failure. Both lean and fat stock are falling in price, and feed is becoming scarce. The hay crop, a very light one generally, has been carried so far in capital order.—June 19.

## AGRICULTURAL INTELLIGENCE, FAIRS, &c.

**BANBURY FORTNIGHTLY FAIR.**—The demand for cattle was very slow; and few sales were effected, even at a reduction on the prices of last market. The mutton trade was also dull, and the price obtained was about 4s. per stone.

**BANNOCKBURN FAIR** drew together a large attendance of dealers and farmers from all parts of the country. The show of stock consisted principally of Ayrshire milch cows, grazing cattle of the sound, useful, and profitable breed, and several lots of calves and stirks from Ireland. The market opened flat for all descriptions of stock; and the dullness which so early indicated itself was not relieved as the day progressed. For milch stock the sale was especially dull; and the same remark is applicable to the Irish cattle. Home-bred animals for grazing purposes were easier got quit of. In the horse fair there was a quiet sale for all kinds; and at the finish of the market the want of customers was made apparent by the number of animals which remained unsold. From Ireland there was a fair show of cob and harness-horses; but a very dull demand took place. The following were among the chief transactions: Mr. Potts purchased calving heifers at from £10 to £12. Mr. Crawford sold a lot of fourteen Crosses at £5, and a lot of stots at £6 10s. Mr. Keir sold

calving queys at from £9 to £10, and milch cows at similar prices. Mr. Goodwin sold calving queys at from £7 to £9, milch cows at from £11 to £12 10s. Mr. Graham sold milch cows at from £10 to £14, fat cows at from £14 to £14 10s., and queys at £7 10s. Mr. McGhie sold milch cows at from £10 to £15. Mr. Brook sold milch cows at from £12 to £14. Mr. Liddell sold milch cows at from £14 to £14 10s. Mr. Waddell sold calving queys at £8, and milch cows at from £10 10s. to £13. Mr. Scott purchased milch cows at from £10 to £14. Mr. Yaill purchased draught-horses at from £28 to £30. Mr. Christie sold draught-horses at from £20 to £43. Mr. Walker sold draught-horses at from £20 to £35, and harness-horses at from £20 to £40. Other sales of a similar nature were recorded.

**BOROUGHBRIDGE HORSE FAIR.**—There was a good attendance of both local and foreign buyers. First-class hunters and roadsters still continue to keep an upward tendency, and the best descriptions were readily sold. A poor show of cab and trap horses, but they had good sale. The best draught horses for town purposes went at paying figures, but other descriptions, which were abundant, went at very irregular prices.

**BOSTON SHEEP MARKET.**—There was a fair supply of fat sheep at market; but, the demand being small, trade was dull, at from 5d. to 6d. per lb.

**BRADFORD FAIR.**—There was quite an average show of horned cattle; but the continuance of drought had an adverse influence on business, and prices had a drooping tendency. The quotations for milch cows ranged from £12 to £21 each, and for geld cows from about £9 to £16 each. Stock of the choicest quality, and commanding the best prices, were in fair demand; but this was quite an exceptional feature in the market. The chief business done was in good draught-horses, which were scanty in number, and commanded good prices.

**DROITWICH FAIR** was well attended. There was a larger quantity of stock for sale than on several previous summer fairs; but the business transacted was somewhat limited. The prices may be fairly quoted as follows: Beef 7d. to 7½d., mutton 6½d. to 7d., lamb 8d.

**LEDURBY FAIR** was rather a small one, except in regard to store sheep, of which there were a good number. Fat sheep were scarce. Stock for the most part were somewhat lower; dealers not numerous. Beef sold at 7d. to 7½d., mutton (wethers) 6d. to 7d., fat ewes 6d. The pig trade was brisker.

**MENHENOT MARKET.**—A large number of cattle were offered for sale. Fat bullocks realized from £3 6s. to £3 10s., per cwt., but there was not a brisk sale. There was a good supply of neat Devon store steers, which, from the plentiful supply of grass, realized good prices. There was a small supply of sheep and lambs. Shearing sheep 6½d. per lb., in the wool 8d. per lb., lambs about 8½d. per lb. There was a plentiful supply of cows and calves, the prices of which had a downward tendency.

**NEWARK FAT STOCK MARKET.**—A good supply of both beasts and sheep, and a fair number of buyers; but trade was slow, and sellers were obliged to give way in favour of purchasers before sales could be effected. Beef ranged from 7s. 6d. to 8s. 6d., the bulk being sold at 8s. Sheep 5½d. to 6d. per lb. Lamb 2½s. to 2½s. each.

**NEWTON-STEWART MARKET.**—Business opened stiffly, the recent fall in the price of sheep having a visible effect on this market. Holders of stock in many instances would have been content with the current figures of last market, but buyers were offering from five to ten per cent. less; consequently, trade ruled very heavy. Three-year-olds ranged from £10 to £12 each, two-year-olds £7 7s. to £9 9s., stirks from £3 to £5. A few left unsold.

**ROSLEY HILL FAIR.**—Horses in great numbers were brought for sale, and there was no lack of buyers. The condition of the horses was good, though of course liberally interspersed with inferior nags. Anything really good was quickly picked up at a very good price; and, indeed, good prices might be quoted for all classes. A good business was done all through the day. Prices for the best class shown ranged from £30 to £50, other classes coming down according to merit.

**ST. AUSTELL MONTHLY MARKET** was well attended both with buyers and sellers, and many good bargains were made. Fat cattle sold at from £3 6s. to £3 10s. per cwt.

**SOUTHMOLTON FAIR.**—There were not so many bullocks exhibited as previous to the outbreak of the cattle-plague, a good deal of business being now done at the homes of the breeders. Fat bullocks sold well, and were eagerly bought at 12s. 6d. per score. One prime lot sold at 13s. per score, but those were the best in the fair. Cows and calves were dear, so were young bullocks and steers, a pair of the latter fetching £30. There was about the usual number of sheep penned; ewes 6d., wethers 6½d. to 7d. per lb., with a rather slack sale.

**STOFORD FAIR** suffered in two ways—from the prevailing dry weather, many farmers being in the midst of their hay-harvest, and those who attended being rather apprehensive about the keep. The sale consequently, on the whole, was dull. Considering the length of time that the fair has been closed, there was a large quantity of fat beasts and yearlings, the best beef moving off at 12s. a score. Yearlings druggish. An average number of sheep, which we quote—ewes 30s. to 48s., lamb 18s. to 27s.

**TARBOLTON FAIR.**—There was a large display of stock, entirely composed of Ayrshire cattle. There was a good attendance of dealers and others. The market proved a dull and sluggish one, and prices were back from recent district fairs. The prices of two-year-olds ranged from £4 to £7, of stirks from 30s. to £4, and of calving cows from £9 to £18.

**TAUNTON FAIR.**—Cattle were not so numerous as in years gone by. Good animals sold readily at the following prices: Fat beasts £16 to £27, store ditto £10 to £15, cows and calves £12 to £18, fat sheep 40s. to 47s., grazing ditto 32s. to 39s., rams £6 to £14. Business in horses was very brisk; the number was much larger than last year, and, taken as a whole, the quality superior, especially those for the road and for agricultural purposes. Hunters fetched £28 to £55, carriage horses £14 to £38, cart horses £10 to £30, hacks £10 to £26, ponies £9 to £18.

**THORNE FAIR.**—The show of horses and beasts was above an average, but very inferior in quality; from £15 to £30 was about the range of prices. For Irish calves £11 to £12 was asked, and small bullocks were sold at £5 15s. each. For English cattle the prices were higher; but very few lots changed hands, good year-old heifers being from £8 10s. to £12, and calves £12 to £16.

**WORCESTER FAT STOCK MARKET.**—Owing to the shortness of keep, there was a very large supply of stock brought to the market, and consequently prices were dull, and in many cases much lower. Beef was ½d. per lb. lower, and mutton ¼d. to ¾d. per lb. lower than last market.

**IRISH FAIRS.**—**MULLAGHCREW:** Prime specimens of beef went to fully 65s., second class from 56s. to 60s. per cwt., and third class from 48s. to 52s. 6d. per cwt. Three-year-old heifers brought from £13 to £15 for those in best condition, two-year-olds from £9 to £11 10s., yearlings from £4 to £7 each. Three-year-old bullocks from £12 to £16, the latter figure being obtained for a prime lot, two-year-olds from £8 to £11, yearlings from £4 to £8. Young springers went from £15 to £17 10s. each, while inferior springers and milkers rated from £9 to £12 10s. per head. There was an immense show of sheep and lambs, and busy buying for shipment. Prices were, nevertheless, a shade lower than late fairs. From 5½d. to 6½d. per lb. were the quotations for wether mutton in the skin, ewes in proportion, lambs from 2s. to 30s. each, hoggets from 32s. to 38s. a-piece. The swine fair was well attended. Bacon rated from 6½d. to 7d. per lb., still holding a smart price. Stores went from 40s. to 55s., and the weanlings from 16s. for the smallest to 24s. for the best.—**NEWTOWN-BARRY:** Beef went up to 61s. per cwt. for prime animals; new milch cows and springers averaged £13 each, strippers sold from £8 to £11, three-year-old cattle from £10 to £16 each, two-year-old £9 to £10, yearlings £3 15s. to £6. Mutton sold from 5½d. to 6½d. per lb., hoggets from 30s. to 40s., lambs 19s. to 26s., fat pigs from 54s. to 57s. 6d. per cwt., stores varied from 34s. to 50s., slips from 16s. to 25s., bone-hams from 11s. to 16s.—**CALLAN:** Yearling bullocks and heifers rated at from £3 10s. to £6 6s. per head. Two and three-year-olds ranged from £7 to £13. First-rate milkers and springers near the dropping realized from £13 to £15 10s. per head, second and third ditto eight to eleven guineas. Young bulls were bought at from £6 to £10 10s. per head. Half-fat cows and strippers ranged from £12 5s. to £15 10s. per head. Some prime ewes averaged 38s. per head, hoggets and lambs 17s. to 30s., and mutton 6d. to 6½d. per lb. Small

pigs in kishes and creels went from 16s. to 23s. each, clips and stores 32s. to 40s.

**CORK BUTTER MARKET, (Friday last.)**—First 102s. seconds 99s., thirds 92s., fourths 90s., fifths 77s., sixths 60s.; mild cured—firsts 106s., seconds 102., thirds 96s. Number in market, 1,590.

**GLASGOW CHEESE MARKET, (Wednesday last.)**—The supply of cheese moderate, 630 having been laid down, chiefly new. To clear off some lots that were lying over, lower prices were taken. Business upon the whole slow. About 18 tons sold. Old Cheddars 51s. to 57s., new ditto 44s. to 49s., old Dunlops 48s. to 55s., new ditto 42s. to 45s., new skim-milk 21s. to 23s.

**THE HARTSIDE SALE.**—A sale of stock at Hartside, in the Cheviots, took place on Friday, May 29, under the direction of Mr. Samuel Donkin. Upwards of 3,000 sheep and lambs were brought to the hammer, besides horses, cattle, and other farm stock. The sheep sales were the great feature of the auction, and the Greensides averaged as follows:—Young ewes and lambs £2 5s. 10d., four-year-old ewes £2 6s. 1d., five-year-old ewes and lambs £2 3s. The Hartside three-year-old ewes £2 7s. 3d., four-year-old ewes £2 6s. 3d., five-year-old ewes £2 5s. 8d., gimmers £1 17s. 5d., ewe hogs £1 8s. 9d., wedder hogs £1 2s. 4d., Dinmonts £1 12s. 2d., old wedders £1 16s. 7d., tup hogs £2 15s. 6d., old tups £2 4s. 5d. The competition was very keen.

**SHORTHORN SALE.**—On Thursday, June 4, a draft of shorthorn dairying cattle, from the celebrated herd of Sir Curtis M. Lampton, of Rowfant, Sussex, were sold on his estate by Mr. Strafford. There was a large company present from various parts of the country, and several of the cattle were purchased for foreign exportation. Among the principal lots sold were a roan milch cow (Fancy) of known blood and from a prize family, to Mr. Roberts for £315, and the auctioneer remarked that this was the highest value ever recorded for a cow in Sussex. A yearling heifer, the produce of this cow, was purchased by Mr. Cheney for £152 5s., and a calf (now but two months old), from the same cow, realized £52 10s., to Mr. Sartoris. Brannette, a milch cow, was sold to Mr. Rigg for £105. Mr. Tracey bought Hebe at £70 7s.; Mr. Akins took Nancy at £79 16s.; and Mr. Downing had Princess at £78 15s.; two other yearling heifers fetched £81 18s.; and three other calves under four months of age produced £69 6s. The sixteen dairying shorthorn cows realized an average of £69 19s. each. The three heifers made an average of £78 4s. 6d., and the four calves brought the average of £30 9s. each, and the herd, consisting of 23 head of cows, heifers, and calves, produced the aggregate amount of £1,475 5s.

**SALE OF A DRAFT OF MR. HARWARD'S SHORT-HORNS.**—Mr. Strafford sold, at Winterfold, near Kidderminster, on June 17th, 34 cows and heifers, and 15 bulls and bull-calves, announced as bred with great care from the stock of the Duke of Devonshire, Lord Ducie, Messrs. Bowley, Maynard, and Rich, and others. Amongst the bulls was Charleston, the sire of many of the cows and heifers offered. A number of gentlemen, farmers, butchers, and others attended. The total produce of the sale amounted to £1,453, the average for the 49 animals being less than 30 guineas each. Lady Jane 2nd, a roan, sire Duke of Bolton, was bought by Mr. Beaseley for 41 guineas; Oxford Lassie, a red, sire Duke of Ormond, by Mr. Mann for 40 guineas; Forest Queen, a roan, sire Fitzroy by Mr. Nash at 37 guineas; Phœnix, a rich roan, sire Archduke, by Mr. Holland at 37 guineas; Duchess of Gloucester, white, sire Mandarin, by Mr. Canning at 31 guineas; Cleopatra the 8th, red and white, sire 10th Duke of Oxford, by Mr. Norris at 45 guineas; Charming Woman, red, sire Royal Arch, by Mr. Blakeway at 34 guineas; Cleopatra 9th, a rich roan, sire Lord Oxford, by Mr. Davis at 58 guineas; Yorkshire Lass, a roan, sire 7th Duke of York, by Mr. Cutler at 38 guineas; Maid of Oxford 2nd, a roan, was the highest-priced female, her sire was 7th Duke of York and dam Maid of Oxford, and she was knocked down to Mr. Cutler for 80 guineas in calf. Charleston is a rich roan, and 5 years old, by Lord Oxford; and his dam, Countess of Berrington, was bought by Mr. Morris for 46 guineas. Mark Antony, 11 months old, made 46 guineas, to

Mr. Munns; and Lord Waterloo 2nd, 6 months' old, 35 guineas, to Mr. Cutler. The local papers speak to "the spirited competition," but according to the prices realised the sale must have been by no means a success.

## ENGLISH WOOL MARKET.

**CITY, MONDAY, June 22.**—We have no change of importance to notice in the English wool-market. The trade continues languid, and the quotations are almost nominal. Stocks are on the increase; but there is soon likely to be a revival in the export demand.

CURRENT PRICES OF ENGLISH WOOL.		s. d.	s. d.
FLEECES—Southdown hoggets.....	per lb.	1 3½	to 1 4
Half-bred ditto .....		1 4½	1 5
Kent fleeces.....		1 4	1 4½
Southdown ewes and wethers ..		1 3	1 4
Leicester ditto .....		1 3	1 3½
Sorts—Combing .....		1 0	1 1
Clothing .....		1 2	1 6

**BRACKLEY WOOL FAIR, (Wednesday last.)**—Business was dull, owing to the absence of the large manufacturers. In the fair there were about 13,000 fleeces of Wool—a larger number, we believe, than on any former occasion. The highest price obtained was 39s. 6d. per tod, the average being 38s.

**BRADFORD WOOL MARKET, (Thursday last.)**—The continuance of a moderate consumptive demand for wool, principally the lustre sorts, is reported to-day. The tone of the trade is rather firmer, owing to the improvement which has taken place during the last few days in the Liverpool cotton market, but staplers allege that they are unable to realise prices proportionate to country rates, which are gradually hardening. As, however, there is a large quantity of wool to come forward, and the drought, should it continue, will have a very injurious effect upon the crops and upon the state of trade, they are not very eager as yet to replenish their stocks.—*Bradford Observer.*

**CUMBERLAND WOOL FAIRS.**—At the annual wool fairs held in Cumberland prices generally have had an upward tendency, and a fair amount of business has been done. At both Longtown and Brampton the prices were nearly the same. The following were the average: Half-bred hoggs 1s. 7½d. to 1s. 8d., Cheviot hoggs 1s. 4d. to 1s. 5½d., mule hoggs 1s. 2d. to 1s. 3½d., Leicester and half-bred ewes 1s. 3d. to 1s. 4d., and Cheviot ewes 1s. 1d. to 1s. 2d. per lb.

**DONCASTER WOOL MARKET, (Saturday last.)**—Another immense market, not far short of 1,800 sheets. These great supplies naturally check business, and trade ruled very flat. Still fine lustre wools were not quotably cheaper, and inferior runs scarcely so. About 6d. per stone would cover the greatest reduction, but for all business purposes last week's prices must be quoted with a slow trade.

**GLASGOW WOOL MARKET, (Saturday last.)**—Fine weather having now set in, clips are coming into the market more freely, and during the week a fair average of bred wools has changed hands. Rates have been well maintained. A few clips of laid Highland have also come in, but as buyers are evidently waiting the result of the sales next week, little business has been done. Rates, it is expected, will be fully tested then. White Highland is not in request.—*F. H. M'Leod.*

**HEREFORD WOOL MARKET, (Wednesday last.)**—There was again a fair quantity of Wool at market, and prices were about the same as last week—viz., wethers 16d. to 16½d. per lb., mixed wool 16d. to 17½d., and hoggs 18d. to 18½d.

**LEEDS (ENGLISH AND FOREIGN) WOOL MARKET, (Friday last.)**—The consumption of English wool is well maintained, and prices are firm, especially for the best quality. The farmers are asking higher rates than can be got for some sorts in the manufacturing towns. Colonial wool is barely maintaining the prices given at the beginning of the sales, and as there is still a large quantity to offer the necessities of buyers can be easily met. Inferior wools are selling at losing prices for the colonists and others.

**LEOMINSTER WOOL FAIR.**—Wool ruled from 16d. to 18d., and to fetch the latter price about one-half of the fleeces were tegs. Lambs' wool was 12d. and 13d., but not so much on offer.

**MALTON WOOL MARKET, (Saturday last.)**—The full clip of wool now being available, there are numerous sellers among the smaller farmers; buyers, however, were not so

eager to purchase as a week ago, and the best wools are not quite so high, the extreme rates not being given. The average prices may be put at 23s. for hogg fleeces, 21s. mixed, and 18s. ewe per 14 lbs.

**STOCKTON WOOL MARKET, (Wednesday last.)**—A good supply of wool, which made the following prices: Leicester, all hogg 21s., two hogs for one ewe 20s., half-and-half 18s. 6d. to 19s.; Cheviot hogg 17s. 6d. to 19s., ditto ewe 14s. to 15s. per stone; Scotch 6d. per lb.

**YORK WOOL MARKET, (Thursday last.)**—To-day there was the largest show of Wool that has ever been known in York, the number of sheets pitched amounting to about 1,500. The business done was consequently slow, and last week's prices could not be maintained. Pure-bred fleeces fetched from 17s. to 22s. per stone as per count of hogg, ewe, and wether fleeces; and clean condition and cross-bred wools sold

at from 12s. to 16s. per stone; locks from 9s. to 10s. 6d., and cots 12s. to 14s. per 14 lbs.

**BRESLAU WOOL REPORT, June 18.**—Owing to the continuance of the German wool-fairs, which are attended by our customary buyers, business is completely at a stand-still. In the meanwhile, large supplies are arriving from Prussia, Posen, Poland, and Hungary, which, added to our remaining stock, form a quantity of about 35,000 cwts. The recent fairs of Landsberg, Dresden, Rostock, Halle, Weimar, Leipzig, and Augsburg had very nearly the same result as our own, and only at Stettin was an indifferent revival noticeable, as combers were purchasing rather freely, and paying for good washed a little more in proportion than at other fairs. The Berlin fair, which begins on the 19th inst., will be a deciding one for the further march of the wool-trade.—GUNSBERG BROTHERS.

## REVIEW OF THE CORN TRADE DURING THE PAST MONTH.

For three weeks the month of June followed the dry hot month of May, with greater intensity of solar power, until general apprehensions were entertained that the drought would seriously affect the yield of corn, as it has already that of hay, which proves a very scanty produce. Some fine rains began to fall on the third week, with more frequent falls subsequently, and we hope they will save much of the spring corn, which was in great jeopardy. Wheat in the light lands suffered quite as severely, whole fields with a gravelly subsoil going off as if by blight, and such lands must be past recovery; but the deep highly-farmed loams scarcely ever looked better, and have been put about a month forward by the extraordinary heat. This is no slight matter at a period of exhausted stocks, being perhaps equal to an import of two million quarters. So the pinch apprehended by many can now never be felt, unless there should be disasters in harvest time. These, however, we have no right to expect, but rather to be thankful that a critical period has thus been met by the kindness of Providence—though, as in all these cases, at the smart expense of some. The rain, we fear, has arrived too late to make a good crop of peas, though it will wonderfully alter the market gardens. The beans, being later, have received great benefit, as well as the late pieces of barley in the cool soils, and also a good portion of the oats. But enough has passed to remind us of our constant dependence, in the midst of the most industrious and intelligent efforts, on the soil; and it affords a striking comment on those sure words: "Neither is he that planteth any, nor he that watereth, but God that giveth the increase." In France, it would seem, opinions vary; but the general expectation is not beyond an ordinary year. Belgium and Holland appear satisfied with their prospects, the soils of both countries, though so different, better bearing the heat. Germany has had rain. There are some complaints in Poland, Russia, and Spain; but America promises an average surplus for export. Our rates have materially altered for wheat under these changed circumstances, the decline being on the first Monday

about 3s. to 4s., fully 1s. of which was subsequently recovered. The following were the recent quotations at the several places named:—The best white wheat at Paris 76s., red 70s. 6d. In Belgium rates varied from 66s. to 68s. 6d., white Zealand at Rotterdam 71s., Holstein red at Hambro' 69s., Saale 67s. 6d., red at Cologne 57s., at Mayence 60s., Berlin 61s., the best high-mixed at Danzig 71s., Serbian yellow at Pesth 38s., red Banat 43s., Upper Canada spring 54s. 6d. per 480lbs. No. 1 spring American at New York 59s. per 480lbs.; No. 2, 67s.

The first Monday, which happened to be the first day of the month, was the time of deepest depression. The weather was most splendid; the home supply of wheat only small; and, though the foreign arrivals were large, they were by no means excessive. Very little was exhibited on the Kentish and Sussex stands; but a sort of panic seemed upon the trade, and, though English factors had not much to clear, they would gladly have done so at a decline of 3s. to 4s. per qr.; but millers seemed in a state of alarm, and left the stands pretty much as they found them. The foreign trade was very little better, factors being willing to submit to a reduction of 2s. to 3s. per qr., without finding more than the most retail custom. The same influence was felt in the floating trade; and some time holders sacrificed several cargoes of Odessa Ghirka wheat at 54s. 6d. per qr., which at the end of the week brought 3s. 6d. per qr. more. The depressed advices from London had considerable effect on the country markets. A few went down more than London—viz., Bury St. Edmunds, Bristol, Gloucester, and Sheffield noting a decline of 4s., and Hull of 4s. to 5s.; but more generally 2s. to 3s. was noted as the decline, and several did not exceed 2s. per qr. Liverpool, which gave way 6d. per cental on Tuesday, recovered on the following Friday. Glasgow was quite panic-stricken, and noted a fall of 2s. to 3s. per boll; but Edinburgh was more moderate, the reduction not exceeding 2s. per qr. Dublin submitted to 2s. per barrel, with but little doing at the decline.

On the second Monday there was a more limited supply of native wheat, but a greater abundance of foreign. The Essex and Kentish stands exhibited very few fresh samples this morning; and the weather having become colder, some reaction was experienced, and 1s. per qr. advance was realised on good samples. More confidence was exhibited in the foreign trade, there being no disposition to force sales; and floating cargoes were fully 1s. dearer than on the previous Monday. The reaction evinced in the London market was much more marked in those of the country; but they varied materially. Though more money was generally demanded, some were only firm; some reported a rise of 1s., as Ashford and Alton; more were up 2s., as Birmingham, Bury St. Edmunds, &c.; others rose 2s. to 3s.; and not a few were up 3s. to 4s., as Boston, Ipswich, Leighton Buzzard, Sleaford, and Stockton. Edinburgh advanced 2s. per qr. Glasgow was only slightly dearer. Dublin reported a great trade, with very little change.

On the third Monday there was a small supply of English wheat, but plenty from abroad. There were but few fresh samples showing on the Essex and Kentish stands; and some were asking more money, say 1s. to 2s.; and in one or two instances, we hear, it was made, but generally we could only note more firmness in the trade. There was, however, more demand for foreign, at the previous currency; and cargoes afloat were a better sale, at fully as much money. With scanty supplies again in the country, and the weekly sales further reduced, there was a hardening tendency in prices. About half the reports were 1s. per qr. higher; a few were up 1s. to 2s., as Ipswich, Leeds, Lynn, Market Harborough, and Market Rasen; yet some places were dull, as St. Ives and Sheffield. Edinburgh was up again 1s. to 2s.; but Glasgow was only slightly improved. All that could be said of the wheat trade at Dublin was, that it was firm.

On the fourth Monday the native supply was again small, but the foreign was the largest of the four weeks. Some fine rains had fallen, and done much good to the wheat on the light lands. A few of the previous week's samples were yet on the Essex stands, increased by a small number of fresh. An effort was again made to realize some advance, but it did not succeed, though everything good was fully as dear. Fine Danzig being very scarce was held high. A steady demand was experienced for the better qualities of Russian and spring American, but low qualities were rather in favour of buyers, and somewhat difficult to place. Floating cargoes were fully as dear. The subsequent advices from the country showed little difference.

The London imports during the four weeks were 8,698 qrs. English wheat, 131,747 qrs. foreign; against 14,947 qrs. English, 103,775 qrs. foreign for the same period in 1867. The London averages commenced at 73s. 9d., and closed at 68s. 5d. per qr. The London exports were 52 qrs. wheat, 63 cwt. flour. The general averages opened at 73s. 10d., and finished at 67s. 6d. The imports into the Kingdom for four weeks were 2,976,449

cwt. wheat, 164,303 cwt. Flour; against 2,330,211 cwt. wheat, 370,608 cwt. flour for the same time in 1867.

The supplies of country flour have kept up very well, considering the difficulty of procuring wheat in the interior; but the foreign arrivals have been moderate. A decline of 1s. to 2s. per sack took place on the first Monday, in sympathy with the state of the wheat trade, bringing Norfolks to 48s., and the better markets in proportion. There has been no quotable change since, business having been quiet. The foreign trade has been also on a small scale, the best American barrels scarcely being worth over 36s. On the third Monday town millers lowered the top price from 64s. to 60s., at which it remains, and does not seem for the present likely to change. The imports into London for four weeks were 50,754 sacks country made, 9,396 sacks 6,540 brls. foreign; against 69,977 sacks country, 20,643 sacks foreign for the same period in 1867. The Paris market has fluctuated much, but closed rather dearer, and above profitable shipments to England.

The arrivals of maize have been moderate, and so has the demand, at about 1s. decline in the course of the month.

Very little British barley has come to hand, but little has been wanting. The foreign receipts have lately been somewhat liberal, though chiefly of a grinding description. The market, though weak in prices through the month, and giving way 2s. per qr., subsequently hardened, in consequence of unfavourable reports as to the influence of the late drought on the growing crop, which in some localities have suffered much; and though the late moderate rains will doubtless save a good many pieces, they have come too late for some that were prematurely forced into ear. Malting prices are of course nominal, but good Saale could be had at 36s. to 37s., and good grinding has lately sold freely at 32s. The imports into London for the four weeks were 1,367 qrs. British, 34,631 qrs. foreign; against 2,075 qrs. British, 24,934 qrs. foreign last year.

The malt trade was very quiet during the earlier part of the month, and tending downwards; but the late reports respecting barley have caused more business, at rather firmer rates.

The entire supply of oats from the United Kingdom has been very scanty, but the foreign arrivals have more than made up for the deficiency, and been very large for the time of year, generally exceeding the expectations of importers from the previous foreign reports. Steamers have helped to swell the amount with Russian sorts, and these with the inferior qualities have given way in value during the month about 1s. per qr.; but so scarce has been fresh heavy corn, and so small its proportion to the bulk of our receipts, that it can hardly be considered any cheaper. Good 38 lbs. sweet corn is worth nearly 28s., but light and inferior has been selling at 23s. As there seems little now left in the country, we shall principally depend on foreign arrivals. It is well some fine rains have fallen, for this crop; as, though forced on at a rapid rate by the powerful sunshine, it was very unpromising a little while back, and we fear now cannot be a plentiful

one. As we know the hay has suffered, we may have another dear season for this corn. The imports into London for four weeks were 957 qrs. English, 130 qrs. Scotch, 880 qrs. Irish, 160,069 qrs. foreign. This grain has lately risen again in France from injury done there, and we may once more have the French in the market for Russian corn, as they have all along been buying in Russian.

The bean supply has been moderate, both English and foreign, yet prices gave way on the first Monday 1s. per qr.; but they have since been hardening, as the haulm is very short and the drought is said to have lessened the number of pods as well as prevented their filling. The imports into London for four weeks were 1,702 qrs. English, 3,280 qrs. foreign, against 2,037 qrs. English, 7,924 qrs. foreign for the same time in 1867.

Scarcely any English peas have appeared at market, and there have only been two small shipments of foreign white. There has, however, been little demand for hog feed, maize being cheaper and barley also; but white sorts, from the shortness of stocks, have kept steady, being worth 45s. to 47s. per qr. The imports into London for four weeks were 79 qrs. English, 1,400 qrs. foreign, against 294 qrs. English, 4,333 qrs. foreign in 1867.

Linseed, in consequence of the short supplies, has been rising till it has gained 2s. to 3s. per qr. from the lowest point, and seems likely to be dear.

In Cloverseed a limited sale has been sometimes made, at about late rates, and it is now held for more money. New samples of trifolium have appeared in France, and trefoil here. Prices not fixed.

#### HOP MARKETS.

BOROUGH, MONDAY, June 22.—Our market remains without alteration, trade showing no improvement, and prices continuing only nominal. The fine weather which has prevailed during the past week has improved the appearance of the plant; but rain is much needed in some districts, fire-blast having already been noticed. On the whole, however, the reports from the plantations must be considered satisfactory. Continental prospects are equally good, making the markets flat. Belgium shows more inquiry, the stock held being small. New York advices to the 9th inst. report the market as very inanimate; and the bine, with few exceptions, is healthy and vigorous in every section.

POULTRY MARKETS.—Goings 5s. 6d. to 7s., Ducklings 2s. 6d. to 3s. 6d. each. Surrey Fowls 10s. to 12s., ditto Chickens 6s. to 8s., Barndoor Fowls 4s. 6d. per couple. English Eggs 8s. to 9s., French to 7s. to 7s. 6d. per 100.

Printed by Rogerson and Tuxford, 205, Strand, London, W.C.

fields too small; and for the first time we saw some underdraining in progress. We are now in Dorsetshire, amidst capital dairies; much meadow land. The country near Gillingham nicely undulating, mostly under grass; the land a heavy soil. Shaftesbury-on-the-Hill to our right; the same order of dairying and culture, with an occasional water-meadow, are seen; the crops of wheat,

oats, and beans are good, but oats late. We now have more culture; the valleys good and grass superabundant; culture good, and preparations for turnips going on. Near Dinton we observed small fields, much grass, and all roughly managed. We come upon much wood again to our right; the Dorset and Wiltshire Downs in the distance. We soon reach Salisbury, where my notes cease.

## ON GREEN MANURING.

The progress which has been made in every department of industrial art during the last twenty years is considerably greater than we are ready to acknowledge, until a careful consideration of the subject gives evidence which proves beyond doubt that advances and improvements, which may be small in their individual character, have carried us far onwards in the path of economy and productivity. The practice of agriculture has during this period advanced as rapidly as any of the industrial arts, and those who have so ably co-operated in promoting improvements may congratulate themselves upon the results which have been obtained. It often happens that when the stream thus steadily progresses, we find that we overlook some matters of interest to which we may again turn with advantage.

One important detail of agricultural practice which has been somewhat overlooked during the interval referred to is again attracting the attention of those who are likely to encourage its extension. We refer to the practice of green-manuring. This proceeding, as is well known, consists in the growth of green crops for the express purpose of the vegetable matter so produced being added to the soil, and thereby increasing its productivity. In some parts of the country the employment of green manures is a well-established and very successful practice—one that is steadily persevered in, and with highly beneficial results, and it will be readily acknowledged that its more extended adoption will in many cases prove to be advantageous.

It does not involve any abstruse theories if an explanation be given of the practice here referred to. In the growth of a crop, we have two sources of food which are available for its requirements. We have the soil, as the source from which all the mineral matter of the plant is derived, together with a small portion of the organic or combustible portion; and the atmosphere, from which the growing plant draws the chief portion of its organic constituents. If the soil had been the only source of food, the growth of a crop could not have added any new material to the land, and could not have increased its fertility in this manner. It is perfectly true that the materials would by the processes of growth have been altered in their condition and modified in their character. Scattered as they might previously have been, and in a condition only slowly available for vegetation, they have been collected by the fine searching roots of the plant, and are in a condition more ready for use than prior to their being absorbed into the growing crop. As a natural consequence, even the mineral matter required for one crop is thus gathered and rendered more immediately available by the assistance of the preceding crop. But when we consider the large amount of vegetable matter which is accumulated from the atmosphere and then incorporated with the soil, we cannot fail to be struck with surprise at the fertilizing matter thus added to the soil. Rich as such manure is in its composition, it has the advantage of being ready for use by the succeeding crop just as the nourishment is required—not liable to be washed from the land and wasted; but as the process of decay pro-

ceeds, so does the decaying matter liberate the imprisoned elements of nutrition, and place them at the disposal of the growing crop.

We must not look upon this increase of nutriment as the only action resulting from the use of green manures; for, if so, it would become a simple matter of calculation whether or not we could purchase these supplies of manure, and add them to the soil, at the same cost. This is, undoubtedly, a very interesting subject for research, and one which will well repay the scientific agriculturist for the consideration it demands, and in its economical bearings will be most important. Few will be prepared for the diminished cost at which a given quantity of ammoniacal manure can be gathered from the atmosphere by a growing crop, and then added to the land, as compared with the purchase of the same quantity of manure, even when obtained in its most economical form. It is, however, upon the mechanical influence of green manures, as well as on their chemical action, that their value so much depends.

Upon the strong clay soils this mechanical action is exceedingly important. Many of these soils, whilst containing abundant stores of fertility, have such a dense and compact character, that there is great difficulty in carrying out the ordinary tillage operations whereby the soil is prepared for the growth of the crop; and after the necessary preparation has been well performed, such soils are predisposed to revert to their original condition, and become as dense and compact as ever. The peculiar influence of green manures upon these soils is that by their incorporation they impart a porosity and friability to the land which very much encourages the growth of the roots. They are thus able to penetrate the soil more freely and more perfectly, and to search for the nutriment required by the crop. This enables the crop to take advantage of the natural fertility of the land; and the cultivator obtains practical proof of its pecuniary importance.

The action is materially modified upon sandy and loamy soils, where we have to contend with an absence of that density and tenacity of character which we desire to overcome in the case of strong and tenacious clay soils. When green manures are ploughed into sandy soils, the action which is observed upon them is an increased capability for retaining moisture; and even manure, which previously could not withstand the wasting action of the rain, but was liable to be soon carried down into the subsoil, is preserved by the vegetable tissues thus added to the land. The influence has been of very great importance upon very light and frequently blowing sands; for by the agency of green manures these have been ameliorated so as entirely to alter their character, and thereby a foundation has frequently been laid, preparatory to the more ordinary tillage operations; and superior turnip and sheep-farms have thus been formed upon barren and worthless tracts of land.

There are, however, certain qualities of growth which should characterise the crop selected for the purpose. Rapidity of growth and a suitability for the soil upon

which it has to be grown are essentially necessary. Mustard, buckwheat, and lupin have been most extensively used, and offer a choice according to the character of the soil and district, each possessing its especial merit, and becoming, under various circumstances, most suitable for cultivation for the production of green manure.

It is also very desirable that the age of the crop at the time it is ploughed into the land should be carefully controlled. Whilst the plants are in a condition of luxuriant growth, and just as they are preparing to bloom, the juices are most fully charged with nitrogenised matters, and are in their richest condition. This stage being passed the condition of the fertilising ingredients changes

in its character, and some of the more valuable become imbedded in woody fibre from which they are not readily available. An overgrown crop is therefore not only more injurious to the land, but it is less useful as a preparation for any succeeding vegetation.

There is another beneficial result which has followed the use of green manures, and especially mustard, which is the destructive influence it appears to exert upon the wire-worm, one of the wheat-farmer's greatest pests. So beneficial has its influence been regarded that in some districts its cultivation is especially encouraged for this reason.

## AGRICULTURAL STATISTICS OF VICTORIA.

We have recently received an official copy of the agricultural statistics of the colony of Victoria for last year, and as there are some important facts to be gleaned from a careful perusal of this document, we shall abstract a few of the statements for the information of our readers. Although some attention is still given to gold mining, the exports of gold averaging about £6,000,000, agriculture and sheep-farming occupy now very prominent places in the industry of the colony. The export of wool now reaches 43,000,000 pounds, or more than double what it was at the time of the gold-seeking mania in 1853. The horses in the colony have quadrupled, there are double the number of sheep, and the cattle keep steady in number and quite adequate to the wants of the increased population; the population in the colony having doubled in twelve years.

The occupied land in the colony now amounts to 7,947,455 acres. The area occupied during the last ten years amounts to 5,840,930 acres, or more than three-fourths of the whole extent of land at present under occupation. The average size of holdings is 325 acres; that of the lots usually devoted to farming pursuits, 104 acres. The average area in occupation to each individual in the colony is 11.5 acres. In the last ten years, settlement has progressed in a faster ratio than population.

The land enclosed amounts to 6,970,106 acres; of this 1,151,228 acres were fenced-in in 1867. The average area cultivated by each holder is 21.7 acres, of which freeholders contributed 70 per cent., and non-freeholders 30 per cent. The average area cultivated by farmers is 25½ acres, and by squatters 52½ acres. Farmers cultivated 18 per cent. of the land they occupied, and squatters 1 per cent. of the alienated land attached to their runs. The extent cultivated by each occupier was greatest in the year 1861, when the average was nearly 31 acres; since that period the tendency has been for settlement to outstrip cultivation, so far as the number of occupiers is concerned. Comparing the land in cultivation with the population of the colony, on an average, 100 acres are cultivated to every 109 individuals. Should cultivation advance in the same ratio, in relation to the increase of population, the next returns should show a proportion of not less than an acre under tillage to each head of the population. This proportion has already been exceeded both in New South Wales and South Australia. In the former colony, according to the latest returns, with a population of 431,000, the number of acres placed in cultivation amounted to 451,000, or a fraction over an acre per head; and in South Australia, during the last season, no less than 4.37 acres were placed under tillage to each individual in the community.

The numbers of live stock returned for Victoria are as

follow: Horses, 121,381; cattle, 598,968, of which 140,414 were milch cows; 8,833,139 sheep, and 74,708 pigs. In ten years there has been a net increase of 73,549 in the number of horses, of 4,191,591 in the number of sheep, and of 22,481 in the number of pigs, but a falling off of 47,645 in the number of horned cattle. There are nearly 15 head of stock of all descriptions to each man, woman, and child in the colony, consisting of about one-fifth of a horse, one head of cattle, 14 sheep, and one-tenth of a pig; and about 111 head to the square mile, namely, 1½ horses, nearly 7 cattle, 102 sheep, and less than one pig.

In all the Australian colonies, including Tasmania and New Zealand, there are upwards of 600,000 horses, nearly 4,000,000 cattle, 38,500,000 sheep, and nearly 400,000 pigs, or more than 43,000,000 head of stock of all descriptions distributed throughout the group. New South Wales still heads the list in 13¼ millions; Victoria stands second, 9,628,000; Queensland third, 8,264,000; and New Zealand fourth, 5,297,000. New South Wales and Queensland are still the great grazing colonies, as they own 2,700,000 head of cattle, and Victoria has under 600,000. As a sheep-breeding colony Victoria stands in an equally good position, surpassing Queensland by nearly 2,000,000, but outstripped by the older colony New South Wales, which owns more than 11½ million sheep.

Passing now to an examination of the agricultural resources and production of Victoria, we find that the most important crop cultivated is wheat, which covered 208,588 acres, and produced 4,641,205 bushels. The average produce per acre was—wheat 22.3 bushels, oats 30 bushels, barley 30.2 bushels, potatoes 2.7 tons, hay 1.7 tons. Four years ago vines only covered about 2,000 acres in Victoria, less than one-half the extent of ground now devoted to that culture. The vines number 8,231,022, more than half of which are in bearing. The grapes gathered last year amounted to 60,659 cwt., of which 43,395 cwt. were made into wine. The cultivation of tobacco is not increasing in Victoria, the acreage having declined from 623 acres in 1864 to 243 acres in 1867.

If we inquire into the area of land in cultivation and the extent sown with different crops in all the Australian colonies, including Tasmania and New Zealand, we find that close upon 2,500,000 acres are under tillage. The greatest amount of cultivation (739,714 acres) and of lands under vines, wheat, and miscellaneous tillage is in South Australia, as is also the largest extent under hay, if New Zealand (which only returns sown grasses and not hay) be excluded. Victoria can boast of the largest extent under oats and potatoes, and New South Wales the largest ex-

### PLATE III.

#### MOUNTAIN DEW: A PRIZE HUNTER.

THE PROPERTY OF CAPTAIN E. N. HEYGATE, OF BUCKLAND, LEOMINSTER.

Mountain Dew, bred by Captain Heygate, in 1862, is by the Era, out of Whisky by Windhound, her dam by Linguist—Dick Andrews.

The Era, foaled in 1840, was by Plenipotentiary, out of Sister to Memnon by Whisker, her dam Manuella by Dick Andrews. The Era, a very neat horse, was successful alike on the turf and the show-ground, having won some good races at long distances, and taken a number of prizes as a stallion calculated to get hunters.

Whisky, bred somewhere in the neighbourhood of Dumfries, and foaled in 1853, was purchased, when a four-year-old, by Captain Heygate, of Mr. Daggs, of Annan, tracing her title to a libation over which the bargain was sealed. The mare, a black brown, was hunted for four seasons, by Captain Heygate, in Leicester, Yorkshire, and Cumberland, and a wonderfully good one she turned out. She never tired, and was a famous jumper, particularly at water, taking one day, at the finish of a long run with the Hurworth, the river Wisk, when no one else would have it; and her owner there and then declining a long price for her from Mr. Cookson. At eight years old, although still quite sound, she was put to the stud, her first foal being born dead; her second, Mountain Dew by the Era; her third, Denmark by the Era; her fourth, Britannia by Ancient Briton; her fifth, Curacao by Kempton; her sixth, a yearling filly O. D. V. by Double X, and a foal, Norma by Ancient Briton, now at her foot. With Denmark at her side, Whisky took the second prize for hunting brood mares, at the Royal Society's meeting at Worcester, and the first prize at Ludlow and Leominster, in the same year; while all her stock have been winners. The successes of the two brothers, Mountain Dew and Denmark, are well known; Britannia, now at the stud, won several premiums as a two and three year old; and Curacao, although only a week up from the field, was the best of her class at the last Birmingham show. The yearling, said to be a beautiful filly, has, we believe, never been out; but the foal was another credit to her dam, as they walked round the ring at Leicester. Whisky herself is rather a coarse-looking mare, showing more power than breeding; but with capital clean

limbs, and she was here again a good second in the brood-mare class.

Mountain Dew is a black horse, now six years old, standing sixteen hands and an inch high. He has a good sensible head, with a neck that was somewhat light; but this has thickened so much since our portrait was taken, that it can now be scarcely called so. He has good shoulders, with hunting withers, and a deep barrel; but he is just a trifle flat in his ribs; he has good loins and quarters, with lengthy muscular arms and thighs, and first-rate joints, while the knee and hock are well let down to the ground. But it is not as a stand-still horse that Mountain Dew is seen to perfection, or even when going round the circus at Islington, or over a course as hard as a turnpike road at Leicester. Let him the rather extend himself on a good reach of ground, with a bit of a bite for his feet, and then will he bring his hind legs well under him in a style never to be forgotten by those who can appreciate the action of a hunter. Mountain Dew, in fact, is something more than a mere show-horse, great as has been his success in this way. He was put into work at three off, beginning the season in Herefordshire, and going on into Leicestershire with his owner's other horses in December. Captain Heygate's own weight is about 12st., but that of his groom nearly 14st., though this difference is apparently none to Mountain Dew, who goes as well with one as the other. Last winter he had a very hard season of it in Leicestershire, coming three days a fortnight, or frequently twice a week, with long distances to cover and home again. Mrs. Heygate often rode him with hounds as a three and four year old, as she still does in the summer as a hack; and he is a very charming lady's horse, with a temper so good, that when lying down in his box, the Captain and his little boys will sit on his back, and he will eat out of their hands. He is a capital horse through dirt, and altogether a perfect hunter, at least until he took to public life; but on this point we shall prefer to let Captain Heygate speak for himself: "I think the horse has been much spoilt by jumping at shows, the worst thing ever introduced, except to collect a crowd. During the early part of last season I could hardly ride him at a fence, he

was so excited; but towards the end I got him much quieter; though this was the reason he refused at Islington." When will gentlemen and sportsmen refuse to give any further countenance to this mountebank business? which, as Captain Heygate so well puts it, is only useful to draw crowds and shillings, and that goes so far to spoil a good horse.

As a young one Mountain Dew did not make much mark in the show ring, having been paraded several times, with nothing more coming of it than an occasional commendation. Handy home, indeed, at Leominster they told the Captain his colt was only fit for a carriage-horse; while at the Bath and West of England Meeting at Hereford in 1865, Mountain Dew, with the stranglers on him, was merely commended in the three-year-old class, while his brother Denmark took the first prize for two-year-olds. A friend of ours, who acted as judge here, maintained from that moment that Denmark was the better horse of the two, but we joined issue in favour of his elder brother, and we ourselves have since "assisted" in awarding prizes to most of the family. At the Bath and West of England Meeting in the year following at Salisbury, however, Denmark again took his first prize as a three-year-old, and Mountain Dew was again commended in his class, being lame at the time from an over-reach which he got when hunting in the spring. In the autumn of this year 1866, Mountain Dew's merits came to be more recognised, and at the Abergavenny Horse Show in October he took the special prize of £25 in a large class of all-aged hunters up to 14st. In the December following, at Lord Tredegar's show at Newport, in Monmouthshire, he won the first prize of £20 for hunters up to 14st., when one of the judges thus wrote to us of his prize horse: "He pleased us more than anything we had seen, having fine even action, and doing all his leaps in splendid form. He must, if all go well with him, turn out a very valuable animal." In 1867, at the second Bath and West of England Meeting at Salisbury, Mountain Dew took the second prize in the All-aged class of hunters, being beaten for first by the famous Irish-Yorkshire prize horse Voy-

ageur; while his brother Denmark was the first for four-year-olds, and his half-sister Britannia the first for three-year-olds. In the following month, at the Bury St. Edmund's Meeting of the Royal Agricultural Society, Mountain Dew was placed third, with a prize of £25, in the weight-carrying hunter class, against Master of Arts first and Voyageur second, of which award we thus wrote at the time: "The more we see of Master of Arts the more are we satisfied that he is a glutton for prizes, and nothing but a show horse after all. He is very well strutting round a circus, but his gallop is nothing like the strong bold stride of a hunter but short and scratchy, as if his knees were tied together. He wants a lesson from Mountain Dew." At the Manchester Meeting of the Liverpool Agricultural Society the black horse got "righted" again with the first prize of £20 for hunters up to 14st., beating amongst many others Master of Arts placed third, The Baron second, Voyageur, Sprig of Nobility, and Buffoon. At the Lichfield Meeting of the Staffordshire Agricultural Society he took the first prize of 20 gs., with Denmark highly commended; and a second prize of £10 at Tamworth, an award which led to an essential difference amongst the judges, the Yorkshireman giving his colleagues a bit of his mind *coram populo*. At Chester he took the one prize of £10 for hunters, at Wirral the first prize of £10, and later on in the autumn the first prize of 20 gs. again at Abergavenny, without any conditions as to weight. In 1868, at the Islington Horse show, he took the first prize of £80 for weight-carrying hunters up to 15st., in a class reaching to fifty of "all sorts," with Voyageur and Master of Arts amongst them. At the Birmingham Horse Show, in another large field, he took the first prize of £25 for hunters up to 15st.; and at the Leicester meeting of the Royal Agricultural Society the second prize of £25, being beaten for first by the Yorkshire mare, Lady Derwent.

Captain Heygate refused £400 for Mountain Dew at Manchester last autumn, but the horse and his brother Denmark are now for sale, as they are rather over-stocked at Buckland.

## PLATE IV.

### THE RETURN PROCESSION.

"English sportsmen will give almost anything for good grouse-shooting; and Scotch proprietors have taken advantage to demand rents which, twenty years ago, would have been incredible. No sooner is a moor in the market than it is snapped up; and thus a large amount of capital is introduced into the country, in addition to the circulating medium which is brought in at the time of the shooting season." So says Murray's *Handbook for Scotland*, as just issued—certainly one of the best works of the kind ever brought out. Although intended more especially for the use of the tourist, there is no class of traveller but who may profit

by occasionally consulting such a guide. The information is *honestly* given—a great point; and if a view or a hotel be not worthy of a visit, the stranger must be very obtuse if he cannot gather as much from his pocket-companion. The advice in this way must be particularly serviceable; but the sportsman, as usual, raises the tariff wherever he goes or whatever business he goes on, and "in some of the more solitary districts of Ross and Sutherlandshires, as the inns are limited in size, they are frequently monopolized by sportsmen;" so that the more general traveller will often find that "even chairs and sofas are not

to be obtained." The laird in the print, however, looks very much above that sort of thing. His house is his Castle; the Hill his own property; and the mountain-hare, the black cock, and the dun deer will receive the attentions of a man-cook, and have their funereal rites flavoured with the best of Burgundy. The pro-

cession has been re-formed early this afternoon, and the dinner-hour may be observed accordingly; but the late Duke of Athole, a very keen stalker, was occasionally out until 11 or 12 o'clock at night; and dinner, of course, was never served until his Grace's return.

## THE MILK WE CONSUME.

BY CUTHBERT W. JOHNSON, F.R.S.

The use of milk naturally commenced with the birth of the first mammalian. The provision thus made by Creative Wisdom for the nourishment of the new-born is far too remarkable to escape the observation of the most careless. When we proceed to examine the composition of that milk our interest and our admiration are increased. We cannot indeed fail to reflect that it was essential to adapt the food of the young animal, not only to its sustenance, but for its growth. This provision, too, was needed, not only for the enlargement of its purely organic parts, but for its bones also. Now, these requirements are all supplied in milk. We shall presently see that in it is contained an ample supply of matters essential not only to the formation of flesh and fat, but also of the phosphate of lime, of which bones are so largely composed.

We here again see the contrivance of a Divine Architect, by which every requisite is provided, every present and future want anticipated, even before the calf is born. The use by man of the milk of our domestic animals dates from a very early period. We find it noted in the earliest book in our possession (Genesis xviii. 8), and also that butter was then made from it. For many centuries the consumption of milk was confined to its use as a beverage, the manufacture of butter and cheese, or in cookery. It was only about two centuries since that its great modern employment in tea and coffee commenced. It is chiefly to the use of milk in this way and its composition that I propose to address myself in this paper. One or two valuable reports indeed have been lately made on this subject, and moreover the supply of milk to the metropolis and to other densely populated places has become of increasing importance to many of my readers.

Milk as an addition to tea and coffee is unknown in China. In that peculiar empire the infusion is made by putting the tea at the bottom of a cup and pouring upon it boiling water; it is then allowed to cool, and drunk without any admixture. Mr. Fortune, who travelled over the tea districts of China, only on one occasion met with sugar and a teaspoon. The Celestials, it appears, regard tea as of a cooling nature, so much so indeed, that the lower orders are wont to counteract this supposed effect by adding to it ginger and common salt.

Before we examine the composition of the cow's milk consumed in London, let us see what is its chemical composition as drawn from cows of different breeds. This important inquiry not long since engaged the attention of Professor Voelcker. He observes in one of his valuable practical reports (*Jour. Roy. Ag. Soc.*, vol. xxiv., p. 308):

"The Shorthorn, though more particularly distinguished for its precocity and excellence as a meat-producing animal, is nevertheless an excellent milking cow. Some families of even pure-bred Shorthorns are, indeed, distinguished in this respect; for, when well fed, they will yield much milk; and at the same time go on improving in condition. On this account they are preferred by many to Ayrshires,

Alderneys, and other breeds of peculiar or local merit, and are becoming more and more the principal dairy breed of England.

"The Yorkshire cow, essentially a Shorthorn, is the favourite breed of cow-keepers in London and other large towns, as it surpasses all others for the quantity of milk it yields. The milk, however, compared with that of the smaller breeds is more watery and less rich in butter, and better suited for direct consumption than for the making of butter or cheese. The statement made by some that pure-bred Shorthorns are not good milkers, is emphatically denied by others. The truth is, there are Shorthorns which are good milkers, and others which are not. As a rule, animals remarkable for the rapidity with which they put on flesh and fatten are not the best milkers, and *vice versa*. Shorthorns, on the whole, perhaps, are more useful for general dairy purposes than any other breed.

"In 1860, I made some experiments with a view of ascertaining whether pure-bred Shorthorns gave more or less, and better or worse milk, than cross-breeds. In the month of September, 1860, three cows from the common dairy stock, and three pedigree Shorthorns, belonging to Mr. Thomas Proctor, Wall's Court, near Bristol, were kept on the same pasture, and the milk from each set of cows carefully measured and subsequently analyzed. The pasture was good and the supply of food unlimited.

"The daily produce in milk was as follows:

"Three common dairy cows gave 31 pints in the morning, 21 pints in the evening, making together 52 pints.

"Three pedigree cows gave 28 pints in the morning, 21 pints in the evening, or together 49 pints.

"The common cows thus produced rather more milk, but the differences were trifling.

### COMPOSITION OF MILK OF COMMON COWS (ON GRASS ALONE) ON SEPTEMBER 18, 1860.

"On evaporation, the morning's milk gave:

Water	...	...	...	86.7
Dry matter	...	...	...	13.3
				100.0

"The evening's milk:

Water	...	...	...	86.6
Dry matter	...	...	...	13.4
				100.0

"As there was no appreciable difference in the concentration of the morning's and evening's milk, both were mixed and analyzed together, with the following results:

Water	...	...	...	86.65
Butter	...	...	...	3.99
*Casein (curd)	...	...	...	3.47
Milk-sugar	...	...	...	5.11
Mineral matters (ash)	...	...	...	0.78
				100.00

\*Containing nitrogen ... 0.66

"COMPOSITION OF MILK OF PEDIGREE SHORTHORNS (ON GRASS ALONE) ON SEPT. 18, 1860.—The morning's milk of the pedigree cows contained 87.6 per cent. of water, and 12.4 per cent. of dry matter, and thus was less concentrated than the morning's milk from common cross-bred Shorthorns.

"The evening's milk contained 86.8 per cent. of water, and 13.2 per cent. of solid matter, and therefore was about as concentrated as the evening's milk of the common cows.

"The following numbers show the detailed composition of this milk in the morning and evening, and the average composition of both:

	Morning.	Evening.	Average.
Water ... ..	87.60	86.80	87.20
Butter (pure fat) ...	3.56	4.16	3.86
*Casein ... ..	3.19	3.37	3.28
Milk-sugar ... ..	4.92	4.86	4.89
Mineral matters (ash) ...	0.73	0.81	0.77

	100.00	100.0	100.00
*Containing nitrogen	0.51	0.54	0.52

"Whether we regard quantity or quality, the three cross-breeds in these experiments gave rather more favourable results.

"After some time all the cows, in addition to grass, received 1lb. of good linseed-cake per head per day, and then yielded:

3 common cows ... 28½ pints of milk in the morning and 18 in the evening, or together 46½ pints.  
3 pedigree cows ... 26½ pints of milk in the morning and 22 in the evening, or together 48½ pints.

COMPOSITION OF MIXED MORNING AND EVENING'S MILK ON SEPTEMBER 24, 1860, COWS ON PASTURE AND 1LB. OF LINSEEDCAKE EACH DAILY.

	Common Dairy Cows.	Pedigree Cows.
Water, ... ..	87.10	86.50
Butter ... ..	4.28	4.28
*Casein ... ..	3.06	3.25
Milk-sugar ... ..	4.84	5.30
Mineral matters (ash)	0.72	0.67

	100.00	100.00
*Containing nitrogen	0.49	0.52
Percentage of solid matter ... ..	12.90	13.50

"The addition of oilcake appears to have slightly increased the amount of butter in the milk, but not the yield of milk itself. After the cows were kept for a week upon 1lb. of oilcake and grass *ad libitum*, 9lbs. of cake were allowed to each animal. The average yield of milk then was as follows:

3 cows produced 30 pints in the morning and 19 in the evening, or together 49 pints.

3 pedigree cows produced 26½ pints in the morning and 21 in the evening, or together 47½ pints.

COMPOSITION OF THE MIXED MORNING AND EVENING'S MILK ON OCTOBER 2 (COWS FED UPON GRASS AND 2LBS. LINSEED CAKE EACH DAY).

	Common Dairy Cows.	Pedigree Cows.
Water ... ..	86.90	86.50
Butter ... ..	3.98	4.19
*Casein ... ..	3.37	3.19
Milk-sugar ... ..	4.98	5.34
Mineral matters (ash)	0.79	0.78

	100.00	100.00
*Containing nitrogen	0.54	0.51
Percentage of dry matter ... ..	13.10	13.50

"It will be seen that the milk of the cows when kept on grass alone was rich in butter, and generally speaking more than average concentration. The grass evidently

was of good quality, and as the cows had plenty of it, we can well understand that the additional supply of linseed neither increased the yield of milk nor its richness. Indeed the yield of milk slightly diminished in October, when 2lbs. of oilcake were given, not, I believe, in consequence of the oilcake, but because with the advancing season the produce in milk gradually decreases, whilst its richness perceptibly increases."

We have already alluded to the marvellous provision made for the formation of the bones of the young in its mother's milk.

When milk is evaporated to dryness, and the dry matter burnt, it leaves, says Professor Voelcker, a whitish ash, which consists chiefly of the phosphates of lime (bone earth), and magnesia. The relative proportions of the several substances in 1000lbs. of the milk of two cows were found by Haiden to be as follows:—

	lbs.	lbs.
Phosphate of lime.....	2.31	3.44
Phosphate magnesia .....	.42	.64
Phosphate of peroxide of iron .....	.07	.07
Chloride of potassium .....	1.44	1.83
Common salt .....	.24	.34
Free soda .....	.42	.45
	4.90	6.77

As regards the effect of cake and other concentrated food upon the quantity and quality of the milk, the general result of the Professor's experiments appears to be, that, instead of adding to the produce or richness of the milk, "the additional food had a tendency to go into meat or to produce fat. This shows that we cannot increase or improve *ad infinitum* the quantity or quality of milk. Cows which have a tendency to fatten when supplied with additional food rich in oil and in flesh-forming materials, like linseed-cake, have the power of converting that food into fat; but they do not produce a richer milk, and they may even produce it in smaller quantity. It is this which renders all investigations on the influence of food upon the quantity and quality of milk so extremely difficult. According to theory it would appear that food rich in oily or fatty matter would be extremely useful for producing rich milk; but in practice we sometimes find that it produces fat and flesh instead. Sometimes its influence is even injurious; for cows supplied too abundantly with linseed-cake produce milk which does not make good butter.

"A very curious case of this kind was brought under my notice some time ago by Mr. Barthropp. He had milk which furnished cream that could not be made into butter. When put into the churn it beat up into froth; the casein would not separate from the butter, even in the cold weather of January. Mr. Barthropp had given his cows linseed-cake in considerable quantities; and this cake, perhaps for want of being mixed with a sufficient quantity of good dry hay, evidently had the effect of producing too much liquid fat. On trying to separate as much as possible the solid or crystallized fat from the liquid fat, I found that the latter was very much in excess of the former. This is the most striking instance of the influence of a great excess of oily food on the quality of cream, and consequently on the butter, which has come under my notice.

"In speaking of the quality of cream, I would take this opportunity of remarking, that bad oil-cake, and particularly bad linseed-cake, does a great deal more harm than is generally supposed by dairymen. The inferior taste of the milk is well known. The wholesomeness of the milk of stall-fed cows is further affected by the abominable matters which are occasionally put into linseed-cake. Oilcake-crushers seem now to have the privilege of incor-

porating any kind of oily refuse with linseed-cake; and since this has been the case, we have heard more frequently of diseased milk, and of milk which has a disagreeable flavour. If cows must have extra food, and linseed-cake be preferred for the purpose, the very best and purest kind of cake will answer best.

"Distillery wash, the acid water of starchmakers, and similar refuse, make milk, as is well known, watery; and this dispenses with the necessity of mixing it afterwards with water. Water is not so much added to milk as it is incorporated in the animal system before the milk is produced. It is well known that acid water, and especially water that contains lactic acid, has a tendency to produce an abundance of milk. When animals are fed with concentrated food, such as bean-meal or cake, it may, perhaps, be advisable—in the absence of brewers' grains or distillery refuse—two materials which contain lactic acid—to generate some lactic acid by keeping barley-meal for some time in contact with water, and by letting it slightly ferment, some vegetable matter perhaps being added, which has tendency to hasten the process. By doing this, I am inclined to think that concentrated food like cotton-cake, or bean-meal, or rape-cake, would be rendered more digestible—more readily available for the production of milk of a good quality."

Having thus seen what milk is in its pure state, let us next examine its quality as commonly delivered to the consumer in the metropolis. On this head we have an abundance of information in the valuable recent report of Mr. J. C. Morton (*Jour. Roy. Ag. Soc.*, vol. iv., p. 70 N.S.) Of the amount of water found in that milk, and of the causes which lead to its great adulteration we need hardly a more graphic account than that given to Mr. Morton, by "one recently in the trade," of whose letter the following is a copy:—

"I suppose it is allowed on all sides that the London milk trade is not what it should be, and that very little pure milk is sold, especially to the poor. Before attempting to remedy this great evil the causes must be ascertained. With the poor, milk is a necessary more than a luxury; and, if pure, it is a most valuable article of food. As sold to the poor it yields a much greater profit than to the upper classes, as the former nearly always 'fetch' it themselves, and thereby save the milkman the expense of distribution, which at a West-end shop costs about 0½d. a quart for a wide-spread business, and 0¼d. for a compact one: and besides this, the rent in a poor district is so much lower. But in spite of all this the poor are the worst served, and the reason is that the trade among them has fallen into the hands of such very 'small' men, who sell so little, that the business cannot yield a maintenance without help from the 'cow with the iron tail.' These same small men cannot contract with a country farmer for his milk, and therefore are in the hands of the wholesale dealers. The wholesale dealers, again, give only so low a price to the farmer that he in his turn, to make it pay, must add a little water.

"And if you go below the labouring class to paupers, they are treated worst of all. We have tendered for five or six workhouses at a price which would have given us a profit of less than one farthing a quart, and yet we have not been accepted. Tenders of 1s. 4d. a barn gallon (8 quarts) have been accepted, or 4d. a barn gallon less than our milk now costs us at our shop; and we are only paying the market value of pure milk in large quantities. The fact that a dealer offered to buy a large quantity of our 'skim,' avowedly to supply a workhouse contract for 'new,' shows what the paupers really get.

"Next, as regards the upper classes, the expense of distribution is so great that only a very small margin is left for profit on each quart; but, on the other hand, the

businesses are generally large. The bar to the sale of pure milk among the better classes is the system of percentages to servants. They all expect 5 per cent. on the gross amount of their master's bills, and this is just about what would be net profit on an honestly conducted West-end business. If this is not paid the milkman is 'worked out.' So, to avoid this unpleasant process, he commences by adding water sufficient to pay this tax, and as that seems to pay well he soon doubles the quantity. We lose two or three customers a week from the servants, but we continually get more new ones, as pure milk will draw in spite of all this.

"I have forgotten to mention a rascally trick of the milk trade, which deserves exposure; I mean the selling cream in quantities short of imperial measure. When we began our business we were forced to have cream-cans of correct measure made on purpose, as the tinman assured us that no dairy-man in London sold cream except in measures 25 per cent. short, and consequently he had no others. We have found this to be true by measuring the cans of many other dealers. The milk, however, is sold in proper measures."

The commercial portion of our inquiry is that of which my reader will very naturally wish for information. On this portion of our inquiry, I will again quote from the paper of Mr. Morton, who has pretty well exhausted the question. He observes (*ibid.*, p. 94):—

"From returns, collected some little time since for the Society of Arts, from asylums, schools, and institutions (not infirmaries, or hospitals, or workhouses, where special dietaries exist), it appeared that 2-5ths of a pint of milk a-day is the average quantity which a mixed population of healthy people consumes when its diet is under medical direction. And in some places the actual consumption approaches this quantity. Thus the town of Stirling, which has a population of 12,500 persons, was then supplied by 190 cows in the town, besides 200 gallons a-day of buttermilk (a most nutritive and useful food) brought in by rail and otherwise. There was here a cow to every 60 people; and this, at the average of 800 gallons yearly to every cow in milk gave 100 imperial pints per annum to every man, woman, and child, or about 2-7ths of a pint a-day a-piece, very nearly the medical standard; and indeed exceeding it when the 200 gallons a-day of buttermilk are taken into account, for this would furnish half a pint a-day to the 3,200 belonging to the labouring class in a community of 12,000.

"The English town of Mansfield may be fairly compared with the Scottish town of Stirling. It contains about 10,000 people, and 108 cows. Taking these at 800 gallons a head per annum, and adding 20 gallons of skim milk daily, of which I heard as being sold in the outskirts of the town, there were only nine gallons (72 pints) per annum for each inhabitant, or 1-5th of a pint a-day a-piece—one half the medical standard.

"Take, now, Bedford:—It contained in 1865, at the time of my inquiry, about 15,000 people, and 100 cows: and 123 gallons of milk, the daily produce of about 50 other cows, were brought in daily by railway. 150 cows to 15,000 people are one cow to 100 people, about the same as at Mansfield; and this, at 800 gallons a cow, is about 70 pints a year, or 1-5th of a pint a-day a-piece—one-half the medical standard.

"If then 1-5th of a pint a-day be taken as the quantity, not which ought to be, but which is consumed in general by a mixed population of English people, then the 3,000,000 of our London population require 300,000 quarts a-day; and this, at 10 quarts a-day from each cow or rather from each stall, indicates 30,000 stalls occupied by cows kept upon the London plan as needed for the London milk supply. And if people were fed according

to the medical rule of our selected institutions, twice this number of stalls, representing about three times that number of cows per annum, would be needed for the supply. At the time of my inquiry into this subject, two years ago, I ascertained that the usual number of cows kept within the metropolitan district was about 24,000; and between 30,000 and 40,000 quarts of milk a-day, in addition to the town production, were then being brought in from the country, which must have needed 8000 or 4000 cows for its production; so that the total number of cows then engaged in supplying London fell considerably short of the number indicated by the average of such towns as Bedford and Mansfield.

"During the cattle plague more than half of the 24,000 London cows disappeared, and the railway delivery of milk rapidly increased, and though, as the London cow-houses have again filled, the country trade has somewhat declined, yet the quantity still delivered is very great indeed.

"The following table, of which the figures have been most obligingly supplied to me by four of the leading metropolitan railways, indicates the growth and, in some measure since the spring of 1866, the decline of the trade.

"It is this aspect of the subject which more than any other is directly interesting to the readers of this journal. So large an increase in the quantity of milk brought up to

town as took place during the cattle plague indicated of course a very considerable alteration in the management and industry of many a dairy district. And as the facilities offered by the London railways increase, and the methods of transmitting milk with safety are improved, so no doubt we may expect an extension of the trade between the London milk dealer and the country dairy farmer. The latter cannot generally make more than 7d. a gallon by cheese or butter and pork or bacon; and if the London milk dealer will give that or a little more at a distant railway station, it may be for the interest of the farmer to give up the expense and labour of dairy management, and in their place incur the risks and costs of a new and unaccustomed trade. The exchange has not always been satisfactory: for until, by cooling the milk before starting and by perfectly filling the cans and carrying them without excessive shaking, the liabilities to souring and spoiling on the road have been diminished or avoided, great losses, especially in hot weather, have been and will be suffered.

"I say nothing here of other risks which interfere with the extension of this trade—the risk of bad debts which the farmer runs and the risk of adulterated milk which the dealer runs—for these are common to all commercial dealings. A London wholesale cowkeeper will receive from his customer who comes to his cowhouse and milks his cows 8d. or 4d. an imperial gallon more than the farmer will receive for country milk delivered, with all its charges paid, at the London terminus; not only because it is the produce of specially fed cows and perfectly fresh, but because it is certain to be unadulterated. I was told the other day by a London milkman that every barn gallon of such milk as his would "bear" a quart of water without any chance of the adulteration being detected by an ordinary consumer; and he had known that quart put in before the milk had left the country farm on its railway journey. The mere risk of such dishonesty is enough to lower the market value of the article to dealers, who probably would rather benefit by some such dilution than suffer from it."

These facts (and other practical details abound in the paper by Mr. Morton from which I have quoted so much) will hardly fail to interest the reader. To the general student, the provision of milk for the sustenance of the young, its chemical composition, and its vast importance, when we employ it in our daily food; will all afford matters of abounding interest. To the agriculturist such details will reasonably suggest the inquiry as to a better supply of food to the milch cow, and of pure milk to densely populated places, and an improved mode of conveyance from distant dairies; and above all, the best means for its preservation until it reaches the consumer, from "the cow with the iron tail," will not escape his attention.

**THE ASSESSMENT OF WOODS AND GAME.**—Mr. Sewell Read and Mr. Jasper More have introduced a bill which runs as follows—"Whereas it has been held by the courts of law that woods and plantations, other than saleable underwoods, are not liable to be rated to local rates: And whereas the right of sporting, when reserved by the owner of the land, or let to any person not being the tenant occupying the land, is not liable to be rated to local rates: And whereas it is expedient that such distinctions and exemptions should cease: Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows: 1. From and after the first of January, one thousand eight hundred and sixty-nine, every description of woods and plantations in England and Wales, not now liable to be rated for

the relief of the poor and other local rates, shall be liable to be rated to such rates, and the occupiers of all woods and plantations shall be rated forthwith, under the provisions of twenty-five and twenty-six Victoria, chapter one hundred and three, and such other acts as regulate the assessment of other tenements and hereditaments to local rates. 2. For the purpose of assessing land let for agricultural purposes the gross estimated rental shall be the full rent at which the land, irrespective of any reservation of game or timber, might reasonably be expected to let from year to year, free of all usual tenant's rates and taxes, and tithe commutation rent-charge, if any; and when such land is occupied by the owner the gross

estimated rental shall be so assessed without any reduction whatever for any game or timber which may tend to greatly depreciate the agricultural value of such land. 3. Where any tenant shall pay any increase of rate by virtue of this act on any land which he may occupy under any lease or agreement at the time of the passing of this act he shall be entitled, during the currency or continuance of such lease or agreement, to deduct from any rent he may pay for such land the amount of the increase of such rate from such rent, and the amount of such increase shall be fixed and declared by the Assessment Committee of the union in which the land is situate."

## ON THE SUPPLY OF MOISTURE REQUIRED BY LAND.

The per-centage of moisture required by land to produce the highest degree of fertility is very various—other things, as temperature, being the same. Reduced to the form of a practical question, it may be thus individually put by farmers: What is the degree of moistness required by this or that field of mine, to place it in the highest state of productiveness, for the different kinds of crops, during the different months of the year? The general proposition, therefore, relative to the quantity of water required by fertile soils to produce abundant crops, appears at first sight very simple. It is, however, otherwise when its details are practically entered upon, for then its dimensions exceed in magnitude those of almost all others in connection with successful agriculture.

The supply of moisture to land to produce fertility is so closely connected with that of air, heat, and light, that in any practical proposition the former cannot be separated from the latter. Thus, when air is excluded by moisture, heat is also partially excluded, much of it being carried off by evaporation from the surface; but when the soil has a proper supply of air in its texture, more heat is absorbed and less carried off by evaporation, so that the difference between the two conditions is very considerable.

The grand question of questions, however, is the proper distribution of air and moisture in the soil, so as to produce the best effect. It is a well-authenticated fact, that the heavy showers of rain which fall at this season of the year on some soils displace much air. Hence the manner they cool the land, taking into consideration the amount of heat carried off by the excessive evaporation after a heavy shower. But when the land is properly drained, the excess of moisture is soon drawn off, when the supply of fresh air rushes in to supply its place. But the two processes thus briefly noticed—the first, the filling up of the interstices of the soil with water, and the removal of air from the soil, with the compression of what air remains within the soil; and the second, the drainage of the excessive moisture and the fresh supply of air—are very different on different soils, and in different states of the same soil. And such diversities depend much upon the distribution of the air and water in the soil, whether by normal or artificial means, *i.e.* whether produced by the natural state and quality of the land, or by drainage, cultivation, manuring, and cropping.

Of natural examples the richest soils are those that maintain a highly subdivided state, and which have much decaying vegetable matter in their texture—land that cannot be drowned in wet weather nor burned up in dry. They are soils that always retain a suitable supply of air and moisture at all seasons for every kind of crop sown, that is adapted for the climate.

These important results are due more, perhaps, to the chemical qualities of such soils than to their mechanical construction. The more practical question, however, is the joint co-operation of both these agencies. Thus the presence of a large amount of decaying vegetable matter has a great affinity for both air and water. It has also a powerful capillary attraction in bringing up water from below, to supply what has been removed by the crops grown, or by evaporation when lying in fallow or before the crops cover the ground. By the former—a strong affinity for water—they not only retain the moisture in them, the force of affinity thus counteracting that of evapo-

ration, but they also abstract from night-dews and the air drawn into them from the atmosphere much moisture, which they supply to the roots of crops. Water is also chemically formed in them during the chemical changes that take place. From the air contained in the interstices of such soils and in the texture of decaying organic matter, and also in the pores of decomposing inorganic matter in a highly subdivided state, much less of it is displaced by heavy showers of rain than what takes place on poor soils of a different description. And, as the air thus left is compressed, its expansive action assists in the drainage of the land. The compressed air thus performs a mechanical function, as well as the chemical one of supplying its oxygen in the process of decomposition. And, as compressed air gives out heat, it keeps up the temperature of the soil to a degree favourable to the fertilising process and the supply of food to plants. From experiments made on the Continent by Schönbein, it appears that, "in every case where water is evaporated, the nitrogen of the atmosphere combines with the oxygen and hydrogen of the water, so as to form nitrate of ammonia;" and from experiments made in this country, when similar fertilising results were obtained, the high fertility of such soils, and the continuance of heavy crops produced by them for years in succession, may yet be traced to the above combined function of air and water in the soil. But, be this as it may, farmers have from time immemorial been familiar with the high degree of fertility which such soils possess under the conditions in question.

Of artificial examples, where a high degree of fertility is produced by drainage, cultivation, manuring, and judicious cropping, those are the richest that approach the nearest to the natural examples relative to a finely subdivided state of soil, air, and water. But in examples of this class the presence of decaying organic matter, and also a suitable supply of the inorganic food of plants, are essentially necessary to produce the required chemical affinity for air and moisture, mere mechanical subdivision being insufficient to produce the desired fertilising effect. Thus some of the poorest and most worthless soils in the kingdom are in a finely subdivided state, and possess a degree of capillary action highly injurious to their fertility, as the quantity of water which they raise and contain excludes the requisite supply of air required by most cultivated crops. Hence their proneness to produce aquatic plants, as rushes, &c.

It follows from these preliminary observations under this head, that the works of drainage, cultivation, manuring, and cropping, require each to be carried out with due regard to the quality of the soil and the nature of the season, in order to fit the land for the retention and supply of moisture to growing crops, works which involve a very high degree of professional skill on the part of the farmer, in order to produce the desired effect. Were soils of a uniform quality, it would be a comparatively easy matter to lay down a general rule for the execution of such works; but uniformity of soils being the exception, and diversity the rule, so to speak, farmers must be guided by their own skill and experience, and not by book rules. No doubt book rules may assist; as for example, *Well-drain the subsoil, and pulverise the staple.* But however truthful and generally applicable such a rule may be, yet when taken to the field, it may just as well have been left

at home on the shelf, for the practical farmer requires as much skill and experience to carry it out as if he had never seen it. In short, the day is gone by when such general rules can with propriety be piped into the ears of practical farmers, for proper drainage and pulverization are questions which convey very different meanings, owing to the wide difference in the requirements of different soils. Thus, what would be generally considered proper drainage for one description of land often proves very imperfect for others; and the degree of pulver-

ization to which some soils can be reduced, so as to place them in the most favourable hygrometrical condition, is at all times a very perplexing, if not problematical question, whose proper solution depends more upon future and unknown conditions relative to the weather than upon the past or present circumstances of the case. To provide for the exigencies of the season in our fickle climate, requires no little skill on the part of the farmer to attain successful results. NEMO.

## THE DROUGHT AND ITS CONTINGENCIES.

BY A PRACTICAL FARMER.

The drought still continues, and the heat of the past week has been extremely oppressive, and almost unexampled in its continuance. We have occasionally had single days with the thermometer equally high, but not for several consecutive days, *i. e.*, from Thursday July 16th to Wednesday 22nd, or an entire week. The drought has now been full fifty-four days in full force, and much loss and difficulty is experienced; and what is more, notwithstanding every appearance and foretelling of rain, none comes. Moreover, the drought commenced at the very time when we were most anxious for summer rains or showers, to cause the growth and progress of our green crops for the sustenance of our farm stock during the ensuing winter. All is yet in abeyance. My fear is that it will prove one of the most disastrous droughts England has ever known. Had it commenced earlier or later, better provision could have been made than we shall now be enabled to make. I remember many trying seasons, but never, I think, one so arid and distressing as the present. In 1817 the drought commenced Aug. 31st and lasted till Nov. 2nd, followed by a severe winter, but then we were well provided with turnips and other winter food. In the next year it was much worse and lasted much longer, beginning May 17th and continuing to Sept. 1st, *i. e.*, 108 days, but there were to be found some tolerable crops of turnips, and the hay crop had a start and was fairly gathered. In 1826 the drought began Feb. 28th and lasted till July 1st, 124 days. This was the most severe visitation of the kind I have known, and the distressing circumstances connected with it may be easily imagined. The heat, too, was extremely great. As for grass, turnips, or any kind of green food, there was none, and straw was all we had to fall back upon, and lucky was he who had a supply of this unusual summer food. In 1840 we had a very severe drought throughout the spring, commencing on the 25th of February, and continued to the 4th May. Such a spring seeding and such dearth of spring grasses I never knew. It was nearly midsummer before the farm stock could be put upon summer pastures. In 1844 we had another severe drought. It commenced March 26, and continued till July 1—97 days. Summer grazing was nearly thrown away, and the re-sowing of the green food crops general; but we obtained turnips and coleseed at last, although inferior crops. Hay, of course, was wretchedly bad. In 1852 we had another very severe spring drought, commencing so early as February 15 and without rain till May 6—80 days, which 80 days gave a rainfall of 0.72 of an inch. The difficulties experienced during this spring were exceedingly trying to every cattle-owner and flock-master. In 1864 we had a very dry summer: the drought began June 24 and did not cease till August 28. The green crops were woefully distressed; and in addition to the drought, we had a deplorable attack of the great drab-coloured grub, which literally consumed whole fields of fine healthy plants of mangolds and turnips, so that in

the following winter the farm stock had to subsist upon straw, hay, and artificial foods. We now come to the present season. We have had but a slight shower or two since May 30, and this is the 27th July. In the east of the kingdom the pastures are everywhere parched up, the turnips in many parts unsown, and those sown making no progress; the spring crops now harvesting are the worst known for many years. The water in all the low countries is becoming very scarce and bad: in some districts the stock has to be taken for miles to a watering, or this is brought to them in carts, or barrels, or tubs, as many farmers do not possess water-carts. The expense and trouble no one knows but those who have to resort to such a practice in a hot season like this—the hottest June since 1868, and the driest since 1826. The stock, however, must have water; of food they have scarcely any; and it is surprising how they live, upon the scanty dry herbage they do gather. Of water they drink abundantly; and animals supplied liberally with cake do not shrink to any extent. The reports of the metropolitan and country markets amply testify to the difficulties of the graziers. Many thousands of both cattle and sheep have been sent in half-fatted, simply because the fields were bare of food, and the stock losing instead of progressing. This must tell severely upon the public ere long. It will be worse than the cattle-plague times. Vast numbers of cattle were then sent for slaughter, altogether unfitted for sale as animals of consumption. The like is going on now; and, in addition, sheep in great numbers are forwarded for sale when only “half-meat.” These were an exemption during the cattle-plague trial; but now they must go, or starve upon the land. In reference to store stock, the difficulties are still greater; they cannot be sold at any price. Already the terms of wintering cattle and sheep are ruling very high. For lambs, one shilling per head per week is demanded. The owners of store cattle must, if possible, retain them till the foldyards are ready to receive them; and then I fear they will have to take very unremunerative prices. The depreciation in price now is full twenty per cent.; and animals purchased to graze in the spring, instead of improving and bringing a full profit, have so deteriorated in condition as to entail a loss of equal amount. These are very serious items to our graziers to encounter; but where is it to end? The contingencies are yet to be provided for. There is a long autumn and winter to tide through, and that almost without hay, or straw from any of our spring crops. Hay is already selling at from £6 to £7 10s. per ton; mangolds and turnips *nil*, there are next to none; cake at an exorbitant price; while wheat straw will be tolerably abundant, but it is indifferent food for stock. What, then, is to be done? It is not only a choice of difficulties, but of difficulties of no ordinary kind. From whence are to come the “material” for fattening either cattle or sheep? Store stock we can sustain in a somewhat thriving state, but how are we

to supply the public with fatted animals? This is the hard problem to be solved. My first suggestion is, that every care be taken to secure the present crop in as good condition as possible, in order that the straw may be kept valuable and nutritious. For this purpose let all the corn crops be cut before they are fully ripe. The corn is benefited by it both in quality and yield, and the straw is much more nutritious. Let every thrashing be very carefully done, and all the straw, pulse, and chaff be husbanded as a necessity for food for stock. In its consumption adopt, as seems most desirable, some of the many devices for enhancing its nutritive value. Steam all tainted straw or fodder, and mix with flaxseed tea, or meal, or corn, or bran, or pulped mangolds, and turnips. All other straw and fodder should be cut into chaff, to be damped, and then add a mixture of any of the above-named or other feeding stuffs. It is to many of these and similar devices that we must resort to carry our farm stock through the ensuing winter. So much for the consumption of fodder.

My next suggestion is, that every available piece of arable land on the farm shall be immediately broken up as cleared of its crop, and be sown with turnips or coleseed, or planted with cabbages if plants can be had. It must be remembered that the harvest is an early one, and if every exertion is made to break up land, either by steam, by the digging breast-plough, by the skeleton plough, by

the common plough, by scarifier, or in any other most expeditious way, good may result. We may have tolerable green crops yet. Be that as it may, it is well worth the attempt to get them. My own crop of early peas has already been harvested, thrashed, and sold, and the land broken up, awaiting rains for sowing it with coleseed. I hope to break up my oat land and much of my wheat land for a like purpose. The crops of green food may not be heavy, but "half a loaf is better than no bread." The crop thus produced may be an incongruous one: it may consist of turnips or coleseed, intermingled with oats, barley, or wheat, grown from the shed corn, but it will be food, and this is what I am aiming to procure. I would in these autumn crops avoid sowing other than the quickest growing varieties of turnips. It is preposterous to sow swedes or mangolds. It may in many cases be very desirable to sow rye for spring feed, or tares, or trifolium; if so, by all means do it. If in any field much wheat is shed, and it is possible to pulverize the surface so as to cause its growth, you have a crop at once growing nearly equal to rye. But I need not multiply these simple suggestions. Every farmer must contrive for himself. I only want to impress upon him that in this unusual season he must adopt unusual practices. No landlord will say, "Why do you do this?" but rejoice in the energy of his tenant, be it a deviation or not from lease or regulated cropping.

## THE NEW FARM.

Alack-a-day! that one must needs write, sultry weather or not! It don't matter that one would mightily prefer just to sit down in the now swift, shallow stream of the limpid Wye the day long, listening (if it could be) to sweet music in the distance, and having birds'-eye and bottled perry within reach. It don't matter that the prevailing heat is such—(Bother the comet that will sweep his tail so near to our gasping planet!)—that one could with advantage, as Sidney Smith said, "get out of one's flesh and sit in one's bones for half-an-hour;" but you see, gentle reader, that when one's mind gets on the fret, 'tis like one's wife's talk, or young pop: it must froth over, under risk of an explosion. I am anxious to tell you the result of my experiments: first, as respects the pelargonium seedlings, the history of whose parentage I gave you in a former number. A few have flowered. With what keen anxiety, and almost hourly visits, did one not watch the *début* of that first blossom! It was all I could do to refrain from opening it, *vi et armis*, when the floret had really begun to extricate its petals from the enclosing grasp of the calyx points. I think old Melon did take a surreptitious peep by help of the grape-scissors, for I cannot otherwise account for sundry marks upon the flower when it did appear, that looked far more like bruising caused by human interference than simple veining due to Nature's pencil. How grievously disappointed I was to find that the flower I had produced by dint of so much painful care actually came out identical, to all appearance, with one of the commonest sorts that old women indulge, with a broken tescot, in their cottage window! "Good bye," said I at once, with Celtic perseverance, "to this fan;" but, behold! the next in size and tint is an eminent triumph, although not so rare-looking a sample as one could have wished. And yet the parents of the first (the failure) are superbly tinted flowers, from the stock of about the best grower in England. However, the farmer, if he would succeed in his profession, must reflect over every experiment: and this is what I did conclude, on my river rock and over the

sweetest of pipes—Why you see that's a new proof, young man, if you wanted one, that if you are to succeed as a breeder in the production of fine animals, at all equal to their parentage, you must select for your elements those that are not only symmetrical in form, but whose striking traits and features have become stereotyped in their nature, so that you can safely rely upon "like" being born of "like." More than ever now I appreciate the wisdom of those shrewd, grey-haired men, of whom the auction ring leans forward to take a good look, when the glass runs out, and a small well-shaped heifer is credited to Mr. So-and-so, at bidding of many hundred guineas. Besides her own sweet feminine attributes and graceful style of person, her character went beyond, upon a long, stout stock of most fashionable sires. There will be little doubt of her producing beauties. Finally, then, whether you would breed Shorthorns or South-downs, or any other "fancy stock," you must provide yourself with the *very best* blood, to begin with, in *well-shaped animals* that have a genealogical tree of indisputable value.

It is no good beginning now to start pedigrees. A great and successful breeder, pre-eminent in the prize-list, lately found out this fact, and consequently made a clean sweep of the lot, a grand selection of cows fetching only a few guineas over butcher's price. He was, doubtless, getting aware of what his customers had long since found out, that there was no satisfaction in carrying his new strains on. Himself endowed with rare judgment and taste, he could generally attain success; but when it came to his elements (only just conglomerate and scarcely baked) being put into less experienced hands, the sad fact occurred that no particular development could be relied upon to issue out. It might be this shape, or that shape, or something of all sorts. Hence, he wisely made a clearance, and will, I expect, now be more fortunate in his prices, when his customers find that the seedlings answer to the parent plant.

There is one disagreeable nuisance to which I am sub-

ject. I don't know whether other Shorthorn breeders suffer similarly. It is, that certain gentlemen, exceedingly worthy in all respects but this I doubt not, come and look over one's young bulls. They always select the best, and ask the price. As a matter of course they wince thereat, and reply coldly, "Mine is only a common dairy herd; I cannot afford that." "Ah! then I'll show you what will suit you at one-fourth the figure. Here's a grand young animal, pure bred, but descended from animals whose owners never took the trouble to enter their stock in the 'Herd Book.' There, now, he is as good as any one I have shown you, only excepting his having no recorded pedigree to show." "Oh dear no, not for Joseph at all! The gentleman-buyer wants the best of pedigrees, although his herd is but a dairy lot of cows, and requires this cheap in consideration of that fact. Just look at the logic of it! Is it to be wondered at that one has sometimes not patience to reply to such application. He never calculates (oh dear, no!) that if, in consideration of his cows' poverty of blood, I charitably sell him at about butcher's price the near relative of a twelve hundred-guinea bull, he may the next day pass the animal on at a stinging figure to the enthusiastic cousin or friend who *does* go in for the terribly high-bred kind, because really after all the bull is better than he requires. And if he does make this second bargain, will he remember the first seller? Will he or will he not? Avant! I have no patience to write further of such. Let them learn to reason, before they insult the feelings of those who like myself have launched their bark in trust upon a costly deep.

"Poor little Dandy; how sorry he will be to leave his mamma!" This was the sympathetic remark of our Benjamin, in respect to one of the three terrier puppies which is about to be sent to a distance, as of course one cannot be

keeping such small deer for everlasting; especially as the lamb question makes one sufficiently sore in regard to the children's pets. Benjamin had not reckoned upon the neighbourhood of his brothers and sisters when this tender-hearted reflection gained utterance. Of course a maternal caress reached him; but, alas! the agnomen of Dandy stuck, and hath given an advantage to his mischievous brother.

Talking of mischief—unfortunately, one day, a month since, a lady, who had been with the "Missus" inspecting the poultry at the farm, quite casually cast a glance of inspection over the half-door of a loose box in which a young Butterfly of ten months holds his reign. She had a white floating veil on, the flutter of which so terrified the young animal, that he jumped and knocked himself about the box quite frightfully. He has since given us much trouble. He will not be soothed, and butts viciously at remonstrance of any sort; whereas up to that period he was as gentle as need be. It is so busy at the farm-house now. Such squadrons of ducklings, each officered by a single matron, dabbling about as dirty and as short-clothed as campaigners upon a heap of fresh vetches in apartments damp as I wish the turnip-ground could be. The burnt coach ashes, of which I carted in quite thirsty some fifteen waggon-loads last autumn, and upon which a shoal of pigs was fattened, has sieved out so beautifully fine, and yet so greasily damp, as to put the bailiff into ecstasies. I am not quite sure that he did not actually taste a crumb on the tip of his finger. I trust the swedes may like it. I have not a seed in yet, nor shall I put any in until rain threatens. Mildew always punishes our early sowers. My seed is reposing the meanwhile amidst a bedding of sulphur, as a precaution against the raids of fly.

VIGIL.

## CENTRAL CHAMBER OF AGRICULTURE.

A dinner of the Chamber was held at Leicester in the show week; Mr. Jasper More, M.P., President, in the chair. After the usual complimentary toasts,

Mr. MASFERN proposed "Success to the Chambers of Agriculture throughout the kingdom," coupled with the health of Mr. J. More, M.P., President of the Central Chamber. They had had the opportunity of seeing the rise and progress of the different Chambers throughout the kingdom, and he thought the way in which they had gone on had been a most satisfactory thing to those who had been the promoters of them. He felt it to be one of the most important steps ever taken by the British farmer. They had always been told in their agricultural meetings to keep away from politics, and to a certain extent he agreed with that course; but there were circumstances in which there was a diversity of interests, and there were cases in which that of the occupiers had been forgotten by their legislators. There was an election pending, and they knew the expressions made use of by gentlemen as to the pressure brought to bear by the different Chambers of Agriculture. He hoped they would support men who would act for the benefit of the agricultural community. He did not care whether they returned a Whig, a Tory, or a Radical; but they ought to return such men as would espouse their cause in a way which, he was sorry to say, was not always done by those who professed to be their representatives. Last night, or rather three o'clock that morning, saw the conclusion of a debate which had occupied the House of Commons three times during the present session. The Bill under discussion had been opposed by some of the representatives of the inhabitants of this county; but the result of the division of last night was one which those present must hail with satisfaction. As to their worthy Chairman, he believed that in his place in Parliament he had felt it his duty to study the interests of the men who returned him—the tenant-farmers of the county of

Salop—and such a man they should seek to represent them. (Much applause.)

The CHAIRMAN, in returning thanks, said he was aware he owed the privilege of being chairman of the Central Chamber of Agriculture to the confidence which the tenant farmers of Shropshire showed in returning him. He felt most proud of it, if it enabled him in any way to promote the interests of Chambers of Agriculture. He was glad that they had met for their first dinner in the county-town of their first president, Mr. Pell, and that they had met on a day in which the agricultural interest had been represented in the greatest strength in the House of Commons. He believed on no occasion had the agricultural interest asserted its power by a majority of more than a hundred, as it had done that morning. They must excuse them being tired, for every member present voted five times between one and three that morning in favour of the Metropolitan Cattle Market Bill. It was impossible for them to meet without making some allusion to such a remarkable fact. He knew that some of them might have a prejudice against discussing politics at an agricultural dinner (cries of "No, no.") He was extremely glad to hear them repudiate that. The first division taken was two weeks ago on the adjournment of the debate; and on that occasion the agriculturists reached the extraordinary majority of 148. They had now to consider how to abate the opposition to the bill. All the Liberal party were not their opponents, for last night more Liberal members voted for the bill than the minority that opposed it. They had, all through the divisions, fifty Liberal members supporting the bill. The conduct of one member of the Government might, undoubtedly, have given rise to the opposition, simply from raising the notion that they were not sincere in the conduct of the bill. The notion of the market was originally Mr. Ayrton's. Lord Robert Montagu, only last session, said that the imports to England were so numerous,

that any restrictions would cause an interference with trade which would be intolerable; that the proposal was "a gigantic system of protection." The matter now rested with the Government. In the Chambers of Agriculture they had a great machinery established, which might be used for good purposes. One of these was the obtaining of county financial boards, not as separate bodies, but as including the representation of farmers with the magistrates at quarter-sessions. He had just ended his labours as a member of the committee on the malt-tax; and he thought the best substitute for the tax would be a brewer's licence; but to carry that out, they must tax private brewing; and whether that could be done, deserved their most attentive consideration. With respect to the subject of the night, the House of Lords came to the conclusion, twenty years ago, that every description of property ought justly to be called upon to contribute to that which the Act of 43rd of Elizabeth contemplated should be contributed according to the ability of every inhabitant; and they had to consider the best means of inducing the next Parliament to give effect to the resolution. He had moved for the reprint of the Lords' committee on parochial assessments; it was being reprinted, and he invited their earnest attention to it. He had no great faith in the results of committee, on agricultural subjects. This one had slumbered for twenty years unnoticed. No one carried out the conclusions of the committee which sat on the Game Laws in 1846. On turnpike trusts and on county financial boards, after from ten to twenty years had elapsed since a committee reported on them, the House of Commons merely said, Refer them to a committee again. If they were referred to committees, it would be owing to the action of Chambers of Agriculture if legislative results were gained. He should like to see Mr. Read Under-Secretary for Agriculture. In two counties where there were such departments minute provisions against the cattle plague had existed since the middle of the last century. He rejoiced to see so many foreigners at the show, one of whom, specially sent by the Emperor of France, he had invited to their meeting to-day. They would see that France was 50 years behind England in agriculture, and Italy about 200 years. He had no great confidence in the results of committees, as they were seldom acted on in legislation. In the House of Commons a private member could not carry anything, and their object must therefore be to get the Government to take the matter up. It was worth their while to consider whether they should not try to get a department of Agriculture into the Government, which circumstances had shown would be a great advantage. The chairman said it was clear that personal property had existed so long without being rated, there must be some strong considerations against attempting to rate it. No one said a word against their view, and he was obliged to place himself in the invidious position of asking a question from an opponent's view. He asked if Sir G. Jenkinson's views were carried out, would they consent to tax English incomes for the poor of Ireland and Scotland? ("No, no.") But it was impossible to legislate for England alone in taxation. Then he wished to know if his property consisted of £100,000 in the Funds, how could they be able to rate him? If they tried to do so at Leicester, he should go to London. If they succeeded in rating him there he should go abroad and invest his money in foreign securities. This is merely a difficulty which he suggested to them; but as he did not wish to oppose their views, he would merely ask them to study the evidence given by four very able men before the House of Lords on the subject. By all means let them try every means to gain their end. Let them go in a deputation to the Chancellor of the Exchequer next November, and see what hope he would give them of the Government adopting their views. He believed county rates ought to be reduced, but by a very different method. Some charges, such as the militia, should be entirely taken off the rates; others, such as police and lunatic asylums, should receive an increased grant from Government. But let them rate personal property as well, if they can. Let them remember, however, that they must be weaker in the next Parliament. The majority of electors would be consumers, not producers; and the extinction of the eight small boroughs the other day would make them at least twelve less in a division, such as the one on the Cattle Bill. He begged to conclude with his hearty good wishes for the success of the Leicestershire Chamber. (Applause).

Mr. C. S. READ, M.P., returned thanks as a very young

member of the Council of the Royal Agricultural Society, and he believed the only one present on that occasion, for the compliment paid to that body. This meeting appeared to him to be, from what little he had seen of it, one of the best which the Society had ever held. They had been furnished with a magnificent site, and from the long lines of stock which he had had the pleasure of glancing through, it appeared to him that their cattle had come out of the affliction which had overtaken them, improved and purified, rather than degenerated. It was the custom in these days to look very gloomily upon the finances of the Royal Society; but when they considered that they had gone through the visitation of the cattle plague, and that in 1866 there was no show, and that last year there was only half a show, and when they remembered that they had reduced their capital stock by £3000, it was not to be wondered at that people should take such a gloomy view of its prospects. On the other hand, the Royal Society was not supported by the tenant farmers as it ought to be, and he thought there was very good reason why such support was not given (cheers). He meant to say that the Council was a pocket borough (Hear, hear). The tenant-farmers who were on the Council were the best and ablest of their class, and the great noblemen and large landed proprietors who take a prominent part in agriculture were very properly represented, but he contended that there was a set of gentlemen on that Council who did all they could, and who spoke, whenever they could, against agriculturists, and always voted against them (Shame!). In speaking in the House of Commons in favour of the Cattle Market Bill, or in favour of Malt-tax Repeal, it was very damaging to the little influence he (Mr. Read) had, to have gentlemen of the Council of the Royal Agricultural Society, getting up and making speeches and voting directly against the agricultural interest. They could scarcely believe that the gentleman who drew up the report the other day against the report of the majority of the Malt-tax Committee—a report which said that the malt-tax was no sort of burden to the British farmer, and who drew up the report of the Trade in Animals Committee, which said that there ought to be the same restriction put upon English cattle as was placed upon foreign cattle—was a leading member of the Council of the Royal Agricultural Society (Shame)! Leaving the subject of the Society, he would now allude to one or two things which had been adverted to by the Chairman. He had told them that he did not believe in the value of committees. He did not think that there was ever in these days legislation without either a committee or a commission preceding that legislation. He would ask them to remember particularly the Cattle Plague Commission, of which he was a member. They recommended the stamping out the disease, and, though that was an unpopular measure at the time, they knew how successful it had been. They also reported in favour of separate markets for foreign cattle, and that was the bill upon which they divided so successfully last night. Therefore, he thought, so far as commissions were concerned, he had proved that they were of some use. With regard to committees, they had recently had a committee on financial boards, and they had recommended that all Boards of Guardians should send representative ratepayers to take their seat at the quarter sessions with the magistrates, and assist them in all the financial business of the county (Hear, hear). They also recommended that in all committees, such as police and finance committees, half of the members should be magistrates and half elected ratepayers. If those recommendations were carried out, what more could they wish for? what more could they desire? They did not want to set up county financial boards with separate and distinct jurisdiction, but they wanted the voice of ratepayers heard in the court of quarter sessions, and then he thought all would go smooth and pleasant enough (cheers). As to the Chairman's remarks upon the Cattle Bill, it was true that they were backed up by 50 independent Liberals; but unfortunately for them, with but one exception (Mr. Lowe), the whole Opposition went continually into the lobby against the agricultural interest. For 35 days, when in committee, they were taunted and badgered; it was said that they wished to deprive the poor of their meat, and that they wanted nothing but protection. What they wanted was thorough free-trade, but it must be a rational free-trade, not free-trade in foreign diseases, which were sure to produce first a pestilence and then a famine in meat (cheers).

The CHAIRMAN said Mr. Reed's remarks were likely to convey a wrong impression as to what he said about county financial boards. He had taken a great interest in this question, and he had always thought it better to have farmers represented at the quarter sessions, in preference to having distinct financial boards.

The meeting then proceeded to the discussion of the subject of the evening, "The pressure of local taxation on real property."

Sir G. JENKINSON said, he had been requested to propose the first resolution—"That this meeting declares that the taxation now levied by local rates bears unfairly upon the income arising from real property, and urges that income arising from other sources ought to bear an equitable share of the poor law charges, and other local burdens." He had had the honour of reading an address on the subject to the Central Farmers' Club. He believed if the matter were taken up by all the Chambers of Agriculture, they would be able to bring in a measure, whatever Government succeeded to office next year, and to compel attention to a real grievance and a real injustice.

Mr. PELL moved "That a committee of the House of Lords, in the year 1850, having decided that the relief of the poor is a national object, towards which every description of property ought to contribute, this meeting recommends the Chambers of Agriculture to support by every means in their power legislation for carrying the principle into effect." In attempting to advance the intentions of that committee, it was necessary he should call attention to the evidence that was given before it, as well as to a portion of the report founded upon that, to which the Central Chamber of Agriculture had called attention. He was bound to tell them that the committee of the House of Lords that sat 20 years ago, directed its attention to other points, besides the one which had been selected for him to bring before the meeting. The committee directed its attention first mainly to the way in which the tithe was assessed upon every person in England. Among the witnesses examined there were two important ones, one he was very sorry to say had passed from among them now, but had left a name redolent of good sense and surpassing ability behind him, the late Sir G. Cornwall Lewis, and another was still living and aiding the agricultural interest by his exertions, the present Lord Malmesbury. The report stated that as a general principle it was impolitic, if not unjust, to levy upon one class of the community all those rates which were to be expended for the benefit of all classes of society, that certain property should be exempt from those rates, and that the rates should attach solely to real property. That this thing had been so for the last 50 years was no reason why it should continue for 50 years more. Upon what did the security of personal property depend? It depended upon the happy feeling that existed between the poor and the rich in this country. How was that maintained and substantiated? By the system peculiar to England, the system of the poor law. If he was right in saying the poor laws were essential in giving the full value to personal property in England, he contended that personal property should bear its share in supporting the poor rate. Sir G. C. Lewis considered that it would be fair to levy a tax upon those persons who now escaped all contributions to the local rates; for example, fundholders, mortgagees, and persons whose income arose from the profits of trade. Could they have any better evidence of that eminent man? He thought he understood Sir G. Jenkinson to say the statute of Elizabeth levied the poor rate upon the real property of the land (Sir G. Jenkinson: I said it imposed it upon real property because there was no other to impose it upon). The principle of the statute was that it should be levied upon real property, and also upon every person in the parish according to his ability; and acting upon that principle the Scotch up to 1845 attempted to levy the rate, and, in fact, in certain parishes in Scotland, still continued to do so. It had been laid down by the Judges that property to be rated must be visible—must exist in the parish; and persons had removed property to other parishes to escape the rating. If a man occupied a house at £100 a-year, and another a farm at the same rent, and another a warehouse at a similar amount, did they pretend that if they laid a shilling rate upon each of these men that they were rating them according to their ability? There was no doubt but personal property should be rated as well as real property, and it would be the duty of the Chambers of Agriculture to take care that this matter was pressed upon the attention of the legislature.

Mr. DUCKHAM moved, "That this meeting calls upon the members of all Chambers of Agriculture to support by every means in their power those candidates who declare themselves in favour of a revision of local taxation." He contended that the present system of local taxation inflicted injustice upon one part of the community for the benefit of the other, and that the Chambers of Agriculture would not be carrying out the objects of their promoters if they did not act in accordance with the resolution which he proposed.

Mr. MAY responded to all that Mr. Duckham had said with regard to Chambers of Agriculture, and believed with that gentlemen, that they were to be made of real service to the country. It had been mooted to him by a gentleman who represented a county, that their association was one-sided. If such was the case, then all he had to say was, that he himself was not so. His only wish was to do that which was the best for all men. He trusted that their Chambers would avoid any impression of what might be termed extreme party feeling. Agriculturists had a great work to perform, and he believed they were in the van of doing it. They were very young, and he did not think they had, as yet, put their forces in the right form. It struck him that the present was the time for them to put their forces in order, not for the mere sake of party politics, which would be detrimental to their success, but simply that they should unite, in order that they might somehow or other teach the country that they, as farmers, were, after all, not so far behind other people as might be imagined. The question was, whether farmers as a class should be taxed, and other members of the community set free. He coincided with the gentleman who had spoken before him that such a thing ought not to be, and he thought it practicable that it should be changed. Why should a penny in the pound be levied for the release of the Abyssinian captives, whilst the captives in our prisons and gaols were paid for from another source? Why should not the same thing be paid for in one way as in another? Why should they build ships of war, or any other expensive armament of the Government, paying a penny in the pound, and not pay in the same way for lunatic asylums, and other parochial establishments? Why should they pay their pennies in the pound to teach people how to kill each other, and not pay to teach them how to live amicably together? His rates had increased something about one-third upon his occupation; they used to be 2s. 6d. per acre, now they were 4s. 1d. Still, he should not grumble if the burdens were borne generally—England expected that every man would do his duty. He said, let him do it, in paying as well as in acting. He most sincerely wished that Mr. Hallett, who was a great man in producing pure seed, would take Mr. Reed, and produce more seed like him—(applause)—and that Mr. Mechi, who was so well-known in connection with thin-seeding, would thin-seed Mr. Reed over the whole breadth of the land, and so produce to the farmers a good crop of admirable men such as he was (Cheers).

Mr. ALGERNON CLARKE (the Secretary of the Chamber) said the resolution called upon them to exert some political action in the next election with a view to ensure the return to Parliament of members who would be likely to carry out the objects of the Chamber. He was quite aware that this was the first time that the Central Chamber had officially taken cognizance of any strictly political action beyond deputations, petitions, and so on; but it must be remembered that the Chambers were not merely farmers' clubs, afraid to take any particular action, neither were they about to form themselves into trades' unions; but at the same time, while there might be an element of danger in the resolution which the meeting was asked to carry out, still there was great weakness in being afraid to pass such a one at all. The resolution, as read by Mr. Duckman, called upon them to support in the next election such candidates as declared themselves in favour of what they might call Chamber questions. He was aware there were two words in that resolution which were originally intended to be put into it, and they were "wherever expedient." It might be that an excellent man might come forward, such a one as they would like to elect, but still he might be dead against the reform of local taxation. Another man, in respect to whom they might use every endeavour to keep out of Parliament, might wish to act strictly in accordance with their view of revising local taxation, and therefore it was thought advisable to say "wherever expedient." What was the use of going up to Parliament and asking their representa-

tives to do something for them, and at the same time being afraid to speak to the candidate before he got there. His object in addressing the company was to ascertain what course the Central Chamber in particular, and provincial Chambers also, ought to take in the coming elections. Were they to have a committee sitting in London to act whenever it was advisable to do so, and so as to carry out the views of the members? or were they to act as the Chambers of Commerce did, never interfere in the elections, and by that means offend neither one party or another?

Mr. C. H. FRENCH rose amidst some applause mingled with laughter. (After considerable interruption, the chairman said it was possible that the interruptions came from gentlemen who were not strictly sober. He should advise them to take a stroll, and cool themselves.) He said, as regarded the resolution then before the meeting, he must say that he cordially agreed with it, but he confessed there were, at the same time, a considerable number of practical difficulties connected with it that required to be well considered before any measure for carrying out such a principle was passed into law. He knew from his own experience the great injustice that was inflicted under the present system, and the great practical difficulties that arose from time to time upon the subject of the income-tax. They knew perfectly well that if they only took up the *Times* newspaper they would be sure to see a return of conscience money sent by individuals who had escaped payment of the tax. He thought the principle suggested by Sir George Jenkinson was a very sound one, and could be carried out precisely in the way that half of the expense of keeping up the police force was refunded by the Government to the different districts that supported it. Everyone, he believed, who had examined the question, must come to the conclusion that there was a great amount of unfairness and injustice as regarded the income-tax. He happened to be a commissioner, and he heard it said that the frauds which were committed in some particular neighbourhoods were almost beyond conception.

Mr. GREEN, M.P., could not see how a parish could with justice be called upon to support a national militia, or when a man was drowned and thrown ashore, the parish, wherever it happened to be, should be mulcted with the expense of the coroner's jury. With regard to putting the expense on to the income-tax, that was a question on which he should not like to give an opinion, but certainly they had heard enough to make them think on the subject. He hoped the day had gone by when there would be any class feeling between town and country, because the interests of both were beginning to be so united that they must go hand-in-hand together; and that which was conceived to be justice to both of them would have to be done.

Mr. TURNER said that the subject they had under discussion was undoubtedly the question of the day. He should like to have it written in large letters in every public building, where it could be seen, that instead of paying on the rental of 1s. in the pound, he had to pay on three. There were £300,000,000 paid to the property-tax, but only £100,000,000 paid to the poor-rate. Everybody knew that that was a fact. It was simply a question of the rule of three, and they should think of it night and morning.

The Rev. E. SMYTHIES thought that something should be done so that during the next Session of Parliament the matter might be taken up as it ought to be. There was only one opinion and one voice as to the injustice of local taxation. Surely in the next election they would have justice done to them. He agreed with Sir George Jenkinson that they should have an income-tax; then instead of having to pay 2s. 6d. in the pound, as at present, their payments might be reduced to as low as 2d.

Mr. NEILD, of Worsley, Manchester, considered Mr. Duckham's resolution of vast importance. He besought them not to let anything go forward which had in it anything like a political bias. He believed there was no question of modern legislation which claimed more consideration or was calculated to do greater justice to the agricultural interests than the revision of local taxation; and in whatever shape it might be presented, there would still be left the broad principle that the agricultural interest, so far as local taxation was concerned, must prove the revision of Parliament.

Mr. RANDALL, of Market Rasen, held that the national exchequer ought to meet all liabilities connected with charges of poor-rates by an imperial taxation founded on an impar-

tial assessment on the entire income of the country. At present they were paying in the dark; for instance, one-third of the poor-rate was devoted to other purposes than the relief of the poor. The local taxation was levied on real property alone, whereas real property only represented one-third of the annual income of the country. The experiment of the blind leading the blind had been carried to a considerable extent. However, there was a great hope that the eyes of the leaders would be opened. It was not long since that these Chambers of Agriculture were formed, but they had already gained a standing in the country, which they would honourably maintain (Hear). They were listened to in the House of Commons, and the proceedings that day had been characterized by an amount of mind and well directed zeal, which could not fail to make its mark.

After speeches from several other gentlemen the resolutions were put *seriatim*, and carried unanimously.

Mr. READ in moving a vote of thanks to the Chairman was most anxious that a fair distinction should be drawn between the politics of agriculture and the politics of party (loud cheers). This was a distinction beginning to be felt; and he could not help thinking that the towns would soon begin to regard this question of land taxation as affecting them also. He was glad to see Mr. Goschen, one of the members for the City of London, taking up similar views the other night in the House of Commons. In dealing with this question, therefore, they must be careful to keep its general bearings always in view. He was, on that account, anxious to see all exemptions abolished. Several kinds of real property—woods, mines, game, &c.—were now exempt from local rates, and those exemptions should be got rid of. No doubt it was a great question, but a national rate for the relief of the poor was beginning to be thought of. At any rate all establishment charges, the cost of lunatic asylums, the militia and such other fixed charges ought to be defrayed out of the consolidated fund; but the casual poor, respecting which the expenditure may be lavish or parsimonious as guardians pleased, were burdens on real property which ought to be supported by the district. The land even then would pay its fair proportion of taxation levied by the State for objects in which it had no special interest. He asked, then, but for a simple measure of justice. It is not for us (said the hon. member) that gunboats rot in Chinese seas; it is not for us that consuls are sent to semi-barbarous powers, who land us in an Abyssinian war and extra income-tax; it is not exclusively for us that large additional grants are made year by year for education; it is not for us that a quarter of a million a year is spent by the Government on art and science (cheers). I say, therefore, that we want nothing but justice, and though we may wait long for it, we will be satisfied with nothing less (loud cheers.)

**THE DEVONSHIRE CHAMBER OF AGRICULTURE.**—The quarterly meeting of this Chamber took place at Exeter; Mr. Elias Ward, of Hangridge—in the absence of the president, Earl Fortescue—in the chair. The meeting took into consideration the propriety of establishing a standard weight for the sale of grain. Mr. G. Radmore, of Thorverton, brought forward a resolution recommending the adoption of the following scale: 1st, Bushel of wheat 80lbs.; 2nd, Bushel of barley 50lbs.; 3rd, Bushel of Oats 38lbs. He referred to the anomalies in the present system. At Liverpool the weight of a bushel of wheat was 70lbs.; at Barnstaple, 65lbs.; at Exeter, 62lbs. Mr. Holley, of Okehampton, seconded the resolution. Mr. Norrish recommended that the returns should be made of all grain sold in the market, and moved an amendment embodying his views, but as there was no seconder it fell to the ground. Mr. Radmore's resolution was then carried, with only one dissentient. The Chairman introduced for discussion the subject of the extent of highway districts and highway rates. He moved "That highway districts should be coterminous with Poor-law Unions." Mr. Holley showed that with regard to some matters there should be a national instead of a county rate. The resolution was carried by a majority of 19 against 4. The Chairman then proposed "That the expenses of maintaining the parish roads should become chargeable to the common fund of each district." Mr. Norrish seconded the

motion. Mr. Risdon, of Walton, thought that the principle propounded was good, and that the resolution expressed what would eventually come to pass. The Rev. W. H. Karalake suggested the formation of a small committee to assist Mr. Ward in ascertaining how the proposed alteration, if carried out, would affect the parishes. He much doubted whether the

county area would not be the best with reference to the maintenance of the highways. The resolution was carried by a majority of 10 against 2. Mr. Risdon gave notice of a motion, that as the general election is approaching the election be strongly recommended to press on the candidates for election the great necessity of more uniform and equitable rates.

## AGRICULTURAL STATISTICS.

On Monday, July 20, at a general meeting of the Thirak Chamber of Agriculture, Mr. CRAIGIE, of Brawith, the Chairman, said they had met together to consider the question of agricultural returns—whether good or bad was to be derived from them—whether should give them their support, or raise their voice against the adoption of them. The subject had now been under discussion a considerable time—in Scotland more so than in England—and in the former country agricultural returns had been tried with great success until lately. The primary cause of these returns being instituted was through the cattle plague. The Government were induced, in March, 1868, to issue the cattle census to ascertain what cattle the country contained, and, in June they imagined the idea of ascertaining the wheat crops. The returns were very imperfect at first, a large section of the community having objected on principle to them; but gradually they have improved. The tax-gatherer is mixed up with them, and there is a great dislike to that word—there was rather a dread of Government, and the returns being sent to the tax-gatherer. He thought they ought to discuss the subject as fully as they could, and ask themselves whether they should give the information, and, if they did so, whether that information would be for the benefit of the country. His opinion was that it was a capital thing, and would be found of very great use to farmers, if properly compiled and prepared; but they had not yet the statistics to enable them to see of what real benefit they were, for some of them rather tended to mislead than to form a proper data. They would all have noticed the great discrepancies from year to year, and by them they could not ascertain whether they had advanced or retired. He thought some arrangement ought to be made in classifying these returns, whereby the man in the south might see what his brethren in the north were farming, and he considered that some arrangement of that kind would be the means of promoting a general efficiency. The present returns do not contain all the occupiers, for he knew himself many in the North Riding who had not sent in their returns. In 1861, 7,099 were returned as farmers and occupiers, and, in 1867, this number had increased to 12,631. Now it was impossible that in six years the number would nearly have doubled itself. He suggested also that if the size of the holdings each man held was returned, it would be advantageous. Before they discussed the general principles of that subject, they should take it on its merits, and that is what they ought to discuss first. If any person present would move a resolution, he had another which he would afterwards move as to details, and which he thought would be of advantage to them. He referred to the agricultural statistics prepared in Belgium, Holland, and France, and the satisfaction that was derived therefrom, and said he had no doubt that, on principle, agricultural statistics would be a great benefit to all of them, and not be detrimental to them. A man's means were not disclosed to the public. What would a general do in battle, if he was not acquainted with the supplies to be obtained? and it was the same with the country at large, who ought to know what supplies they had at hand; for if the aid derived from foreign countries was cut off, they would have no idea of the resources of this country. He briefly referred to the question of estimating the total crops, which would, in his opinion, be found very difficult. They knew the area, but he considered it would be injurious to couple the estimate with the area. It was very necessary they should have agricultural returns, and those returns should be as complete as possible (applause).

Mr. RINGROSE (Osgodby) inquired of the Chairman whether, in the Scottish statistics, there was not some estimate of the counties.

The CHAIRMAN replied that it was attempted in three counties.

Mr. RINGROSE agreed with the Chairman that a great deal of objection had been taken to the statistics being associated with the revenue offices, as it then appeared as having a connexion with taxation. He considered that if the facts were collected by the Board of Guardians, it would be less objectionable to the public at large. If the statistics were collected by them, they might form an estimate in committee. Some farmers he knew of would be afraid to give a correct return for fear of their landlords coming upon them for a higher rent; others would make their crops greater than they really were, merely from a spirit of bombast. He thought that on looking over the area they might themselves make a pretty good estimate of the crop. He concluded by moving the following resolution: "That this chamber records its opinion of the value of agricultural statistics, and suggests that that there should be a further development of the system now in force, in order that greater accuracy may be obtained."

Mr. APPELYARD (Angram) thought if the farmers discussed the question as they were doing that day, there would be no more objection to agricultural statistics. If they ask their neighbours why they do not send in their returns, the answer given is that there is no advantage to them in doing so—they did not know what they were for. If every person properly understood the object of the Board of Trade in making out these returns, he was sure there would be no more objection to them. A copy is sent to the farmer, six or eight weeks before harvest, to fill up: he is to give his estimate. If they estimate the quantity of quarters per acre they must be very far wrong; and if the farmers were called upon to do that, there would be a strong objection to it. This, however, is not what he is required to do. He is only asked to give an estimate of his entire crop. If farmers were called upon to give an estimate of quarters per acre, the landlords would see it, and, perhaps, raise the rents. He could not see any objection to the present system, and he had great pleasure in seconding Mr. Ringrose's proposition.

The CHAIRMAN next referred to a discussion which had been raised in the House of Commons, on the advantage of having a separate department for agriculture, having it represented in the Cabinet, and doing away with the returns to the Board of Trade. Perhaps they would not exactly have a minister of agriculture, but some person holding a similar position—a secretary for managing the agricultural affairs of this kingdom. There was no doubt of the failure of agricultural statistics as commanding respect from the farmers, and this would be best removed by having the statistics collected entirely independent of all Government offices. He called their attention to the trouble in gaining information during the cattle-plague; they were referred from one person to another, and never knew from whom they were getting proper information, or from whom the restrictions came. What they wanted was an executive, and under that organization the Chambers of Agriculture would be most useful to them. They would not then be responsible to Parliament, but would be independent of Government altogether. Agriculture formed the great back-bone of the country, and although a large portion of the community could not be occupied in commerce, yet they could in agriculture. A proper system of agriculture was, he thought, a thing that could not be over-estimated, and their object was to make the whole of the agriculture of the kingdom to radiate from one centre. Whatever party be in power, it should be their object to look after the interest of agriculture. He thought that since agricultural statistics had been introduced they had certainly conduced to the benefit of the farmer, and would still more so if collected as they recommended. He proposed "That this chamber considers that

agricultural statistics would be more efficiently collected were they compulsorily done by a national department of agriculture, and in its opinion it would be for the good of the country if such a department was instituted." He next referred to the subject as taken up in the House of Commons by Mr. Acland, and said that more than £70,000 a-year was spent over the services rendered to agriculture, which was very badly represented. What he suggested was that there be a commissioner of agriculture appointed, who would be responsible to Government, and by that there would be not only a considerable saving effected, but the work would be carried out much more satisfactorily than at present.

Mr. BARLEY (Ongodby) seconded the motion, and then proposed "That the best mode of distributing the form of returns would be through the medium of the overseers of the poor for

each township, and such returns to be sent by each occupier under seal to the department of agriculture."

Mr. BARNETT (Birdforth) seconded the motion.

Mr. RINGROSE thought statistics no use unless they were made up soon after sent in, and he considered they should be placed in the hands of a local man, and made up by him.

Several members objected to this, on the ground that their affairs would then become known in the locality.

Mr. WYSE (secretary) suggested that this question stand over until another meeting, and moved "That no mode of collecting these returns be approved of by this chamber that does not ensure perfect secrecy so far as it relates to each particular occupier."

Mr. Barley agreed to withdraw his motion; and that proposed by Mr. West was carried.

## MALT-TAX REPORT.

[We gave the substance of the following report which has just been issued.]

The Select Committee appointed to inquire into the operation of the Malt Tax have considered the matters to them referred, and have agreed to the following Report:

1. Your Committee opened the inquiry by taking evidence from the Board of Inland Revenue, and the chairman of the Board (Mr. Stephenson) put in a statement of the different rates of duty on malt from the year 1897 (when it was first imposed) to the present time, as follows: "In 1897, on its first imposition, it was 6d. a bushel; in 1713, when it was extended to Scotland, it was 6d.; and in 1726, in Scotland, it was reduced to 3d. Then, in England, in 1780, it was raised to 9d. a bushel; in 1780, it was raised to 1s. 4d. a bushel, and to 8d. a bushel in Scotland. Then, in 1785, the duty was imposed in Ireland, at 7d. a bushel; that was raised in 1795 to 1s. 3d. Then in 1802 it was respectively 2s. 6d. in England, 1s. 8d. in Scotland, and 1s. 9d. in Ireland. In 1804, which was a year of war tax, it was raised to 4s. 5d. in England, 3s. 9d. in Scotland, and 2s. 3d. in Ireland. In 1813 it was raised to 3s. 3d. in Ireland; and in 1815 it was raised to 4s. 5d. in Ireland. Then in 1816 the duty was reduced to what it had been prior to 1804—viz., 2s. 5d. in England, and 1s. 8d. in Scotland, but it was reduced to 2s. 4d. in Ireland. In 1819 it was raised to 3s. 7d. in England and Scotland, and 3s. 6d. in Ireland. Then in 1822 the duty was fixed at 2s. 7d. uniformly, at which it stands at the present time, with the exception of 5 per cent., which was added in 1840 to the excise duties generally, making the actual impost 2s. 8d. For a short time, from 1854 to 1856, there was a duty of 4s. during the Crimean war, and after that it reverted to 2s. 8d., as it stands now." Following this statement, with regard to the amount of tax, Mr. Stephenson stated as a remarkable fact, that the amount of malt consumed had remained almost stationary for 100 years prior to 1830, although the population had largely increased; that during this period the consumption was 25,000,000 bushels a year, and that on the repeal of the beer duty in 1830 the consumption rapidly increased, until in 1866 it reached 45,000,000 bush. for England only. In 1866 the amount of malt on which duty was paid in the United Kingdom was upwards of 52,000,000 bushels. These statements lead your committee to the conclusion that a reduction in the rate of duty would lead to a large increase in the consumption of malt.

2. Your Committee proceeded to examine several agriculturists of great practical experience, taken respectively from all parts of the country. These witnesses appeared to your Committee to be generally of opinion that the effect of the malt-tax is to interfere with the due rotation of crops, by causing wheat to be sown where barley could otherwise be sown; that it causes inferior barley to be neglected for malting purposes, though it is well known that such barley would make good malt; that it causes the labouring classes to consume an unwholesome kind of beer; that it prevents the farmers giving their labourers wholesome home-brewed beer; that it prevents to a great extent the agricultural labourers brewing beer in their own cottages; that it prevents the farmers making malt on their own premises, as used to be the

custom, it having been given in evidence that in the counties of Essex and Cambridge few of the farm-houses were formerly without malt-houses attached to them. It has been proved to your Committee that malt is valuable for feeding purposes, and that the Excise restrictions, in preventing barley being sprouted for the feeding of horses and cattle, are injurious to the agriculturist.

3. Your Committee next examined maltsters from the counties of Suffolk, Norfolk, Hertford, Lincoln, Devon, and York; from whom your Committee gather that the number of maltsters has sensibly decreased in the last few years, whilst the quantity of malt manufactured has increased; that although some of the witnesses were favourable to a repeal of the tax, they admitted that the trade, as a whole, were opposed to the repeal, on the ground that it would lead to an increase in the number of maltsters, and to the practice of malting by farmers; that the tax compels the maltster to use more capital in his trade, by at least 50 per cent., than would be otherwise required. The Committee feel bound to observe that it is given in evidence that the revenue officers offer every facility to the maltsters in the conducting of their business.

4. Your Committee examined two eminent corn-factors, who are large buyers of home-grown barley and large importers of foreign barley. Their evidence goes far to show that, although in certain localities abroad first-class barley can be grown, yet that as a rule the best English barley would always command a higher price than foreign barley for malting purposes.

5. Your Committee also examined three gentlemen eminent as public brewers, who generally state that the consumption of beer has increased very much of late years; that more capital is required with the tax than would be required without it; and that public-house beer is not adulterated to their knowledge. Mr. Allsopp asserted confidently that the public brewer can and does deliver beer cheaper to the consumer than he can brew it for himself. Two country brewers were also examined, the first of whom objected to the repeal of the malt-tax, as he could see no good in it, whilst the other was of opinion that it would confer great benefit on the public generally, but especially on the labouring classes.

6. Your Committee also examined Mr. Gurdon, of Brantham Court, Suffolk, who has a plan for commuting the malt duty by levying a duty on the malthouse, according to measurement; a plan which certainly appears to have some merit, but upon which your Committee are not prepared to express any further opinion, inasmuch as it is novel, and requires to be considered by the officers of excise.

7. Your Committee next examined, on behalf of the consumer, a manufacturer employing large numbers of workpeople on the borders of Lancashire and Yorkshire, and a very intelligent labouring man from Playford, Suffolk. The latter, Elias Amos, stated that he was a farm labourer at Playford, and that he brews in his cottage three times a year; that he could brew oftener, and that he and his family should use beer instead of tea if malt were cheaper, as they can do more work on it; that

he can do more work on the beer he brews than on public-house beer, which is not wholesome. He says all labourers in his country would brew if they could afford to do so. The former witness, Mr. Joshua Fielden, of Todmorden, gives important evidence as to the extent to which cottage brewing is carried on at the present time. He caused an examination to be made, from house to house, in seven townships situate in the parishes of Halifax, Huddersfield, Calverly and Rochdale. The total number of families visited was 9,822, and the result is that 76 per cent. of these families brew at home, 8 per cent. would brew but cannot afford to do so, 6 per cent. buy their beer, 10 per cent. do not drink beer.

8. The witness accounts for the prevalence of this habit, by the fact that the wages received by a family in the manufacturing districts are so much more than those received by a family in the agricultural districts. He also states, from his own experience, that those who practise it are the least given to frequent public-houses, and are the most sober, steady, and industrious of the population. This witness contends that the malt tax being laid on the raw material increases in pressure at every stage of the manufacture or change of hand through which it passes, and he arrives at the following results: that, taking the price of barley at 31s. a quarter, the tax, when paid by the malster, is 70 per cent.; that the person who buys malt and brews beer from it pays a tax of 100 per cent.; and that the person who buys beer by retail in a public-house pays a tax of 140 per cent. Your Committee are of opinion that the principle on which this calculation is based is correct, and that the consumer of beer pays a very much heavier tax than goes into the Exchequer.

9. Two large distillers were examined by your Committee, of whom Mr. Menzies was anxious that the distillers should

be allowed to make beer from some portion of his wort, and that the duty on such beer should be charged in the same manner as the drawback is now allowed on exported beer. This witness, with all the large Scotch distillers, presented a memorial to Mr. Gladstone to this effect, in 1866. But your Committee must add, that the second witness dissented from this proposition. He also thinks that a reduction of the duty on strong wines would interfere with the spirit duty.

10. Your Committee concluded this part of their labours by examining Sir Charles Presaly (formerly Chairman of the Board of Inland Revenue), and Mr. C. B. Forsey (Surveying General Examiner of Excise). The first of these witnesses stated distinctly that there would be no difficulty in raising a tax from private brewers; and the second could point out no insurmountable difficulty in substituting a brewer's licence instead of the malt tax.

11. Your Committee consider that the result of the evidence taken by them is, that the malt tax prevents the farmer from cultivating his land to the greatest advantage; that it obstructs him in the use of a valuable article of food for cattle; that, by making it necessary to employ a large additional amount of capital in the important trade of malting and brewing, it has created and tends to foster two large monopolies; and that, by materially increasing the price of beer, it encourages adulteration, and prevents to a great extent the habit of brewing amongst the labouring people.

12. Your Committee, carefully reviewing the whole of the evidence before them, are of opinion that the malt tax might be repealed, provided some means for raising the same amount of revenue, if required, be substituted either in the shape of a brewer's licence or some other form.

July 13, 1868.

## THE CATTLE PLAGUE ACT.

(From the Supplement of the *London Gazette* of Friday, July 24—Saturday, July 25).

From and immediately after the 26th day of July, 1868, Article 26 of the Consolidated Cattle Plague Order of August, 1867, shall, with respect to the metropolis, be read and have effect as if the words "ten days" were therein substituted for the words "six days."

The schedule to the Metropolitan Cattle Plague Order of August, 1867, shall be read and have effect as if the words "eleven days" were therein substituted for the words "seven days;" and the forms of Metropolitan Cattle-market passes shall be altered accordingly.

The word "animal" means exclusively an animal comprised in the definition of cattle; and the word "calf" means exclusively a calf not more than 14 days old; and, subject thereto, words in this order have the same meaning as in the Metropolitan Cattle Plague Order of August, 1867.

Notwithstanding anything in the Metropolitan Cattle Plague Order of August, 1867, cattle may be moved alive out of the metropolis, in accordance with the provisions of this order.

Where any person being the owner of any animal within the metropolis which, except in the case of a calf, has been in his possession not less than eight weeks, or which, in the case of a calf, is born from a cow which has been in his possession not less than 28 days, is desirous of moving such animal alive out of the metropolis, he may give notice of such his desire to the local authority by writing, stating:

The fact of the requisite possession as aforesaid;

The name and residence of the owner of the animal;

The name of the person to whom, and the place to which the animal is to be sent;

A description of the animal, stating its sex, breed, age, distinctive marks, and other particulars sufficient for identification.

On receipt of any such notice the local authority shall, unless there appears to them good reason to the contrary, and on being satisfied of the fact of possession for the time requisite under this Order, proceed, as soon as may be, to cause an inspector appointed by them under the Contagious Diseases

(Animals) Acts to visit the cowshed or place from which the animal is desired to be moved:—

In all cases within three days after the receipt by the local authority of the owner's notice; and again,

In the case of any animal other than a calf, at the expiration of 28 days from the day of the first visit (both days inclusive); but

In the case of a calf, at the expiration of seven days from the day of the first visit (both days inclusive):

And to report to the local authority on the state of health of the cattle in the cowshed or place aforesaid.

If in the case of any animal, the inspector, on each such visit, is satisfied and reports that it and all other cattle in the cowshed or place aforesaid are entirely free from contagious or infectious disease, and that it has not, since his first visit, been in contact with any cattle other than those in the cowshed or place aforesaid, then the animal may be moved alive out of the metropolis at such time within three days after the second visit of the inspector.

Cattle brought to the metropolis by the London and North-Western Railway may be moved alive within and out of the metropolis by the London and North-Western Railway to Willesden station, thence by the West-London Railway to the junctions with the London, Chatham, and Dover Railway, and with the London, Brighton, and South-Coast Railway, at or near Long Hedge, and thence by either of the last-mentioned railways out of the metropolis.

Cattle, the produce of Spain or Portugal, or of Normandy or Brittany, may be landed at any port in Great Britain, along the coast from the North Foreland, westwards to the Land's end, and thence northwards to the Mull of Cantyre, at places approved by the Commissioners of Her Majesty's Customs.

Until cattle landed from a vessel under this Order have been examined by an inspector appointed or approved by the Commissioners of Her Majesty's Customs, they shall not be moved from the place of landing, or be allowed to come in contact with any other cattle.

## LEICESTERSHIRE FARMING.

"A plough in a field arable," says Cowley, "is a most noble and excellent coat of arms." It was a home-truth quaintly told, and one not to be lightly gainsaid. Still the decision of the twenty Midland farmers, who met to celebrate the victory of Salamanca, and then sent off the best score of bullocks in their pastures to "Sir Arthur," touches the real key-note of Leicestershire farming. Drayton, it is true, could think of no other title for the county than "Bean Belly," when he strung together in his "Polyolbion," "the blazons of the shires;" but the lapse of two centuries and a-half has placed bullocks before beans, and wethers before wheat. Its "rich and marly plain" hath, according to Burton, "the proportion of a Hart, broad at the top and narrow at the bottom, which name it truly beareth, for that it lieth almost in the hart and center of the whole continent of the kingdom." Except where Bardon Hill rises more than eight hundred feet, above

"the craggy bound,  
Ragged and high, of Charnwood Forest ground,"

where you meet, as Herbert\* did in harvest-time, those silent workers in cowl and gaberdine, under the shadow of the cross upon the rock, the county is pretty generally a succession of gently-rising hills, of which a south-eastern range separates the basin of the Soar from the Welland. It contains 816 square miles, or about 535,346 statute acres †; and extends 45 miles, north to south, from Normanton in "Bever's bathing vale," to Stanford Park, dear to the Pycheley; and forty, from east to west, between Wymondham and Nether Seal. Its 335 parishes lie in seven hundreds, and the present county valuation is £1,063,686. The population, according to the census of '61, was 243,648, with the males in a minority of 6,202; while the sum total showed an increase in sixty years of more than eighty per cent. By the same tables we find that there were 194 landed proprietors; 3,483 farmers and graziers; 1,051 farmers' sons, grandsons, brothers, and nephews above fifteen engaged on the land; 128 farm-bailiffs; 567 shepherds (out-door); 2,547 servants (in-door); and 16,182 agricultural labourers.

It is not a county of large farms. Nearly half of them, except on the grazing or Harboro' side, are under 50 acres; there are not many above 500, and one of 700 or 800 acres is quite an exception. On the Harboro' side, or "Top Leicestershire" as it is often called, they usually average from 200 to 300 acres, and are let, in some instances, at from fifty to sixty shillings, but more generally from forty to fifty. Large fields, let by the half-year for keeping, will make 24 and upwards. From thirty to forty shillings is the average for plough farms all over the county, but some of the best are let at fifty shillings, and 23 in very isolated cases. Nearly all the farms on Charnwood Forest are small. In the Vale of Belvoir they more resemble those on the Harboro' side in extent, but increase to 400 acres on "The Heaths," or Waltham side of the Duke of Rutland's property.

There are scarcely any leases in Leicestershire, and except upon a few estates competition has increased rents considerably during the last twenty years. The custom of the country as regards unexhausted improvements has grown more liberal, but it is still less so than in Notts. An allowance is generally made to the out-going tenant for draining done by him within six or seven years, provided he has paid for the tiles. If the landlord has found them, the allowance for labour only extends over four years. In some instances a portion of the cost of unexhausted artificial manures is allowed, and so for the most part is one-fourth of the oilcake consumed in the last two years of the tenancy, if no crop of corn has been grown from it. When wheat has been sown on a clover ley, the out-going tenant generally receives 3s. to 5s. per acre for herbage, but not any rent, rates, or tithe; and there is also a three-years' allowance for bones on the lighter soils, and a two-years' one for lime. On mangolds, cabbages, or potatoes £1 per acre is allowed for the unexhausted value of farm-yard and artificial manures; but it is not so with turnips.

There is a lack of good farm-buildings, although a gradual improvement is going on; but much remains to be done, especially in cattle-yards and field hovels. At present many farmers cannot tie up nearly enough beasts on turnips and straw. This system is preferred for the sake of economising food, but there are too often only sheds for half the number, and the rest run loose in the yards, and are often unable to lie down in very rough nights. There has been no lack of spirit among landlords and farmers in the purchase of good implements. Private steam ploughs are kept at Keythorpe, Garthorpe, Prestwold, Gopall, and Burton-on-the-Wolds, and until lately a Smith's cultivator was let out near Twycross; but the ploughing is generally done with two horses, and three on the stronger soils; and the old wooden plough is not yet extinct. Reaping machines and steam thrashers are let out, and one of the most useful combinations we met with, was that of a pulper and a straw cutter, discharging into the same "well" and raising the mixed fodder by a hoist and funnels either through the wall into the carts outside the barn, or the storehouse within. Many Irish reapers still come over, but the machine and the scythe are gradually superseding the sickle. The scythe is, perhaps, most in favour, as it acts best upon strong land, which the machine cannot get into. During harvest, the men seem to prefer taking out much of their increased wages in ale or beer rather than in money, and the agreements as to extra hours, supper in the house, &c., are so various that hardly a dozen farmers could speak to just the same practice. Men-servants hired in the house get from £15 to £20 with rations, and, exclusive of hay and harvest times, when they earn more than double, a labourer's wages will average from 2s. to 2s. 3d. per day.

"Matters of antiquity, history, armory, and genealogy in the countie of Leicester, whose beauty hath long been shadowed and obscured," found their earliest chronicler in Burton, whose work was printed in "Little Brittain, neare unto Aldersgate-street," in 1622. The north-east and south-west sides were credited therein with "good soile and apt to bear corne and grasse." The vale of Belvoir was "inferiour to none neere adjoining for goodnesse and deepnesse of soile," and when cloud and mists hung over its Castle tower, the rustics looked

\* In allusion to Herbert B.A.'s celebrated picture of "*La borare est arare*."

† Vol. iii., Census (1861) Report, p. 80.

up from their toll, and thought of "this old prognostick rime there currant"—

"If Bener have a cappe,  
You churles of the vale, looks to that!"\*

The north-west side for the most part bore a hard and barren reputation. "It yieldeth fruite not withoute great labour and expences, but is still riche in pitcoale and limestone, wherewith they doe husbande their grounds," as well as plenty of wood and fuel, in which the south-east was wanting. Of the latter side, our author wrote that it was "almost all champion and yeeldeth great delight and profit in every way save one." "It affordeth," he added (and this is the earliest allusion we find to its sheep), "many goode and large sheepe pastures, breeding a sheepe to that height and goodnesse, so that (as I have credibly heard) neither *Lemster* nor *Cotswould* can exceed them if one respect, either largenesse of the body, finenesse of the wool, or goodnesse of the breed."

A similar work was "attempted by John Throsby"—under the Whartonian motto, "Knowledge is to be drawn from particularities"—late in the eighteenth century, and a very elaborate one by Mr. Nichol, in the present. The agricultural history of the county entered very little into their plan, and Quaint Old Fuller did little more than make merry with its "masouline beans," and the good silver which they caused to rattle in the pockets of the "stout yeomen," upon whom he strongly pressed the need of a Friday market. The Board of Agriculture commissioned Mr. William Pitt to report progress before 1790, and his elaborate labours are alluded to by Mr. Marshall, in his "Abstract of the Reports." The latter gentleman had himself written the "Rural Economy of the Midland Counties," and resided for that purpose, in 1784-87, at a small village near Tamworth, where four of them meet." His analysis of his rival's authorities (one of whom was the celebrated Dr. Darwin) are sufficiently caustic, and he treated all quotations from his own works in Mr. Pitt's Report as "pearls set in a shifting beach." He found, it seems, no land worth less than five shillings an acre, and few on lease worth less than ten. From fifteen to twenty shillings per acre was the valuation he put on the county generally, "which no other county, Rutlandshire excepted, can bear."

Arthur Young carries us back to 1771, when he left his Bradmore farm for a tour through the North-West Midlands. "Such as were pleased to give intelligence to the author during the course of his tour" were neither few nor chary of speech. He entered the county from Northamptonshire, with his mind full of a close of 212 acres, belonging to Sir James Langham of Hazelbeach, which "waved over the side of a hill, with herds spread out to the eye, more like a patriarch's of old." He had gazed on the 6,000 acres in Naseby field, from which the Ironsides, scarcely a hundred years before, had chased the Cavaliers into Market Harborough, at the close of a bloody summer's day. Booth of Glyndon had shown him cattle of the longhorned Lancashire sort, and a two-horse Rotherham plough. As he rode on his way by Leicester and Loughboro' to Dishley, which Mr.

Coke always styled "the best inn on the road," he "saw a new tool called a spud" at Mr. Ayer's, of Tilton; and found Mr. Shuckborough Ashby a right pleasant guide to the farms round Quenby Hall. He set the average rent of land at sixteen shillings, and of the best grass land at thirty; and he met with no commons but Charnwood Forest and Rothley Plain. He wrote strongly on cabbage in preference to turnips, and considered that spring cabbage for beasts and autumn cabbage for sheep, with barley or oats for straw, should be cardinal points of a new county system. Beef, pork, and mutton were then only 3½d. per lb.; and the consumption of tea, both by labourers and the recipients of pariah relief, surprised him not a little. A lean eighteen-months' wether brought its £1, and a fat one ten shillings more. It was not the practice to send them up to Smithfield out of the grass, but they were placed on turnips for some weeks near Hatfield or St. Albans.

Of the longhorns he gave a much more favourable report than he did of the shorthorns, and estimated the hide at fifteen shillings more to the tanner. Nothing seems to have struck his attention so much as the eleven to thirteen feet, which were taken up by the hedge and posts and rails of the ox fences; and his proposed substitute was a bank between two ditches with posts and a line of feathers on the top, "which not even a deer would jump." There was, however, nothing left for him to desire, when he found the "Bakewell Junior" of that day among his cow-teams. Dishley seemed to him "incomparable in every particular of good husbandry," and with such clean-kept quicks that they were "bigger at three than others at six." His longhorns were "all as fat as bears;" and it was their great improver's boast that an ox of 50 stone had 30 of it in roast against 30 in boil. One part of his stock management was, to say the least of it, peculiar. He rotted the sheep he would not sell to breeders before he sold them to the butcher; and he did so by putting them on pastures over which water was always flowing after the middle of May.

The geological structure of the county has this especial feature, that the change of soil from light, sandy, or gravelly loam to stiff marl is by imperceptible shades. Its different formations are so blended, that we can hardly speak with the decision of the late Arthur Clough, when he described himself, during a visit to his old school, as standing on the blue lias at Rugby, with the red sandstone westward at Coventry, and four miles off the Northamptonshire villages, "all built of their native yellow-brown oolite, and whose peasantry, in their fustian gaiters and knee-breeches, have a yellow-brown oolitic appearance." The eastern part is mostly occupied by the oolite, the blue and white lias, and the intermediate formations; and the rest consists generally of the new red sandstone, and occasionally of gypsum, with vast coal-deposits commencing on the borders of Derbyshire, and skirting Charnwood Forest on the west. It is in this coal-district that the Flora is richest. No less than 165 and 155 species can be gathered in the course of a stroll round Castle Donington and Ashby-de-la-Zouch respectively; whereas you may search Syston pariah at the fertile junction of the Soar and the Wreake, and only find 72.

The hills of Charnwood Forest are varied and boundless in their mineral stores. "Switland Slate pits" has a familiar sound both to the contractor and the foxhunter. Whittle Hill furnishes hones for scythes. Cement-limestone is found at Barrow in horizontal layers, one or two feet thick; and granite blocks for the London streets are hewn from the rocks in the new red sandstone round Mount Sorrel and Quorn. The uplands are in some places gravelly, but mostly consist of a greyish loam, more or less tenacious in its texture. There are eight

\* Mr. Marriott, of Kibworth Harcourt, in Top Leicestershire, who has registered the rainfall for several years past, informs us that the average for 1856-67 is 23 inches 54 parts, and that the highest rainfall for any year was 30 inches 18 parts in 1866; each part signifying the one hundredth part of an inch. The years 1857, 1860, 1862, and 1865 are next in order. In the driest year, 1864, the rainfall was only 18 inches 4 parts.

† This is Mr. Mastin's computation in his History of Naseby, but the award of the Enclosure Commissioners in 1822 puts it down at 3,375 acres.

kinds of loam between Melton Mowbray and Normanton, though few but a geologist could detect the shades of difference, as the soil shifts from "sound grey" at Waltham to snuff-coloured" at Braunston, and then to the strongest or "deep grey," which dips from Stathern Point into the vale of Belvoir. Sheep-management varies considerably upon them. In the meadows of the Wreake, near Melton Mowbray, lambs are very seldom wintered. Between Thorpe Arnold and Grantham the sheep eat the turnips off the land, whereas in the vale of Belvoir the cold clay bottom will not admit of it.

The soil is generally deep and not easily burnt up. It may be divided into three great leading classes—friable clay loam for corn and grass, sandy or gravelly loam for barley and turnips, and excellent meadow pastures along the rivers. There are frequent deviations in management, according to diversities of soil and variation of seasons; but the four-course is most general. On the lighter soils the following rotation is usually adopted: 1st, fallow for root crops; 2nd, barley with seeds; 3rd, seeds; 4th, wheat. If the farmer wants a two-years' ley instead of corn, when he seeds his land down, he sows white clover with the usual mixture of rye-grass, &c., and red clover if only for one year. The quantity required per acre for the former is one bushel of 25 lbs., which costs twenty shillings. On heavier soils the six-course rotation is followed, to wit, 1st, dead fallow or roots; 2nd, wheat or barley seeded down; 3rd, seeds; 4th, wheat; 5th, beans; 6th, wheat or oats. If more than one year's seeds are required, and the plant will stand, a second year may be taken, and one less in corn. On the land round Tooley, which naturally "grasses" well, four or five years' ley is adopted, which enables a farmer to stock very heavily with sheep, and then break up for oats, when eight to nine quarters have been obtained per acre. In the Upton district the six-field course often runs thus: 1st, break up for oats; 2nd, wheat; 3rd, turnips, mangold, peas, beans, potatoes, vetches, or dead fallow, or a mixture of these crops; 4th, barley; 5th, seeds; 6th, seeds. In many cases, the second year's seeds are dispensed with, and the five-field course adopted. The practice is very variable, as some parishes in this district grow very good wheat and beans, while others suit turnips or barley. There are farms in which no particular course is followed, but that crop is taken which seems likely to pay most at the time. As a rule, in the south-western district the oat crop is worst and wheat and beans best.

Upon the clay lands a dead or summer fallow is generally taken; but on the lighter soils, in order to start the rotation, a crop of swedes, white turnips, or mangolds, &c., is grown. The turnips are principally consumed on the land, and the rest drawn off and eaten in the yards. The old system of pin fallows (sometimes called bye or bastard fallows in Northamptonshire), which consists in breaking up the wheat stubble in autumn, cross ploughing, scarifying, harrowing, and burning the twitch preparatory to putting in the barley crop, is very much gone out, as, except in very dry seasons, it cannot be done with advantage. There is, however, much less necessity for it than formerly, as twitch and couch grass are rapidly disappearing before a higher system of farming.

On some of the lighter soils the wheat is stocked heavily with sheep in the spring, in order to consolidate the root. If the weather is fine, and the land in good condition, the plan is considered by many, apart from the keep thus obtained, to act nearly as well as the clod-crusher and roller, as it prevents the plant from lodging so much in a wet harvest time. If ewes and lambs are put in, there is sometimes danger of the best lambs dying very suddenly from eating too freely, or from the change it produces in the milk. The stronger land, which will not bear treading, is very seldom stocked, and some far-

mers have calculated the loss at harvest by doing so at a quarter of wheat per acre.

The wheat, which is principally winter-sown, is, like the barley crop, very generally drilled in, which enables the farmer to hoe it in May at much less expense, and far more efficiently. This is nearly always done with the hand-hoe, but the patent poppy-extirpator or light harrow has been used across the drills in light soil with very good effect; and if this is done early enough in the spring, before the weeds have got deep hold, it dispenses with hand-hoeing altogether. Its effect is very good, as the extirpator does not draw away the soil from the plant like the ordinary harrow, but moulds it up. The usual rate of seeding for the oat crop is about four bushels to the acre, which is very often sown broadcast. The most improved mode of putting in the bean crop is dibbling by hand, with the aid of a line across the ridges in rows sixteen inches apart. The holes are then kicked in by the attendant boys, and one harrowing (which can be deferred a fortnight, if necessary, for fair weather) with a pair of horses finishes the operation. This mode of management leaves the subsoil much less "set" than when the crop is drilled in with three horses, and has had two harrowings as well.

The horse-hoe is rather falling into disuse, as, independently of the loss occasioned by trampling down the headlands, the work is very much better done by hand; and as the horse-hoe cannot act without damage under 20-inch rows, there is a great saving of space, and the yield is for two reasons better in consequence. Two or three beans in a hole are preferred to more, and when the plan is followed out by a clever setter, the rows would delight even a Dutchman's eye.

Lime is used extensively on breaking up the clover leys for the oat crop, and is also mixed in large heaps with ditch scourings, &c., and the addition of salt, as top-dressing for grass-land. When yard manure is drawn out into the fields, the cart is generally driven on to the heap and tipped, in preference to forking up the dung loose, and allowing a second escape of ammonia. Some farmers put a two or three-inches coating of soil on the top to fix it, when the heap is finished. Lord Berners bore testimony a few years since at *The London Farmers' Club* to the value of covering manure until the time for spreading. His lordship observed that "he had ordered the manure to be covered up in heaps as it was brought into the turnip field, and so to remain until it could be spread and ploughed in. The result was, that in the month of September there was one portion of that field, which had been so covered, where he was up to his knees in plants, whilst the other was only a little above his ankles. Inquiring of the bailiff what could be the cause of the difference in this otherwise fine crop of swedes, he was told that at that particular part of the field where the turnips were smallest, the labourers had been caught in a thunder-storm on the Friday afternoon, and could not get to work again until the following Tuesday. Consequently the manure had remained uncovered for four days; and it was plain, from the very first springing of the turnips until they were gathered in the winter time, where the men had left off. In another field the wheat-stubble was in one part so strong that he could scarcely get his pointers into it, and it was as high as his knees. Mentioning this to the bailiff, the latter said, 'If you mean a point from a certain oak-tree in that field where the stubble is so strong, I can tell you the reason. It was this: You came to me, and found fault with me for not having covered up the heaps just at the tree, and it was from that point that we covered them up for about six or seven acres.'"

The tendency of late years, in the grazing districts, has been to increase the arable as ancillary to grass-land,

so as to manufacture as much meat and wool as possible. There was a day within the late Dick Christian's recollection, when he rode in a run from Cant's Thorns "thirty miles on end to Harboro', and grass all the way;" but since that proud and happy time Old Pasture has quite bowed its head to new prices. Towards Loseby and Twyford, which were both in the line, the plough has gained on the grass; and about Great and Little Dalby fully eight hundred acres of inferior land has been broken up within a few years. The plough has also stolen a march round Prior's Coppice and Owston Wood; and on the hill-side, between Braunston and Withcote. Carlton, Noseley, Shankton, Keythorpe, and those Top Leicestershire districts generally, are all keeping more sheep on their grass-land by the aid of roots; and it has been found that, by breaking up a fourth of four hundred acres of rather mossy pasture, which will hardly keep a sheep in winter, a farmer is enabled to double his flock. There are many graziers who have no plough-land; but they seem to be coming round fast to the opinion that "those lands which are one-fifth on the plough are occupied most advantageously." On the strong clays between Melton Mowbray and South Croxton there is very little change; but in the East Foscate Hundred some fields have been laid down, simply, as was observed to us, "because farmers tire of working with four horses for forty shillings a quarter." Near Loughborough laying down is rather the fashion; but on Charnwood Forest a great deal of land has been broken up for turnips, followed by barley, with two years' seeds, and then oats, and it is rather a common practice to penfold the oat-stubbles with Sheep. On the Leicester Forest and Bosworth side there has been very little change, but, if anything, in favour of laying down, though some bad old pasture has had the plough put through it. On the Duke of Rutland's estates, the temptation to "make the corn-sacks walk to market, instead of being carted there," has induced many to lessen their arable land; but we should say that, speaking of the county as a whole, more furrows are turned up every year, but more with a view to the meat-market than to Mark-lane.

Long Clawson and Hose, in North Leicestershire, have no mean fame among pastures; and some of the best on the Harborough side are on the clay at Lubbenham, Oadby, and Great Bowden, and carry one bullock and nearly two sheep to the acre. Glooston and Cranoe, which were once wheat-land, have been laid down; and Glooston is said to feed bullocks as fast as that famous 100-acre close, Old England, by the Welham-side. The best pastures are always grazed; but bones and liquid manure are very seldom used, and they receive no top-dressing beyond knocking the dung about; while the inferior ones are top-dressed, before they are shut up for hay, with a little lime, and sometimes with nitrate of soda. A ton and a half of hay per acre is a good average crop; and two crops are very seldom taken. Of the management of grass we have spoken more fully in connection with cheese-dairy farms.

Leicester, Loughborough, Market Harborough, and Melton Mowbray are all large wheat-markets, more especially Leicester, which is chiefly ruled by the Liverpool quotations. The farmers always sell, as at Nottingham and Grantham, by the "18 stone nett of 63lbs." to the bushel. The Vale of Belvoir grows good beans and wheat, principally red, but inferior in skin and quality to that grown on the gravelly soils, which commands one or two shillings more. Barrow-on-Soar and Cossington, both of them on the cement-limestone (which has a large proportion of phosphate), grow the best description of white wheat; and there are also some capital crops at Diseworth, and between Breedon and Donington. Charnwood Forest combines fair wheat and barley with good

oats. The land about Upton also suits it as well as beans; and red wheat is the favourite in the Harborough country. Round Loughborough both red and white wheat are used pretty equally; and a mixed quality is also much liked, and thought to yield better than either. The Essex White is sown more round Barrow; and its fine "pastry"-flour is so esteemed that the Nottingham and Derby millers send it to Manchester and Sheffield, and make three or four shillings more for it. Improved and Druce's White are also in fashion; and so is Romer's White, more especially on high-conditioned land. Golden Drop and Browick or Bristol are also "well-accustomed" reds, but not equal in quality to the Red Lammes or Old Red, which sometimes produces five quarters from a fallow crop, and breaks so well in the mill.

It is on the whole rather a fluctuating county for barley, which is not very first-rate, and is principally consumed by cattle. The climate does not suit it, and colours it too highly for pale-ale purposes, and it grows so much straw that it is apt to get laid. If the Burton brewers purchase it they choose the Chevalier, but Earl barley from the Harborough market is their sheet-anchor. Many farmers grow the old long ear, a rather coarse luxuriant sort, with sometimes twenty corns on a side. Queniborough has some "quality barley" on its sandy loam; and Cossington is nearly as famous for it as for wheat. It is also grown pretty good, but, like the oats, with no great strength of straw, on Charnwood Forest, and, in fact, all the way from Dishley to Leicester, through Quorndon, Mount Sorrel, and more especially at Syston except in very dry seasons. Hardly any is grown in the Harborough country except about Smeeton, and taking one season with another, for beautiful colour and malting purposes, the midland brewers depend most for their home supplies on the thin, stony soils near Stamford.

Oats are not so much cultivated, and for the most part on ground newly broken-up. Old turf ploughed-in leaves more in the land to feed future crops than when it is pared and burnt; but the oat crop is very liable to be attacked by the wire-worm unless liming and clod-crushing are very carefully carried out. Paring and burning are a more popular though expensive process, and many landlords object to it on account of the future deterioration of the land, especially if it is too deeply done. Turnips are often sown instead of oats, a plan which gives six weeks longer for burning, and then two or three white crops can be taken in successive years, if agreements will admit of it. The Canadian Poland oats require a deep soil to mature them, and the earlier they are sown the better. Black One-sides or grey oats thrive best on very well-conditioned soil, and Scotch Potato have less straw and are generally ten days later. Tartarians are little sown, and Frieslands flourish bravely round Melton Mowbray, and go principally to the Matlock millers. The Harborough side grows this crop pretty well, but the largest supplies come from the parts about Leicester and Loughborough, and are chiefly Canadian Polands, weighing "18 stone nett of 45½ lbs. per bushel." The bulk of them goes to Nottingham, and some of the finest samples to Manchester.

Leicestershire is not given to "rejoice in potatoes," and its home supplies are principally drawn from the Lincolnshire fens. A considerable quantity was once grown on the north of the county, but "since the disease they have dwindled to a tenth;" still they hold a place in the green-crop rotation on the Duke of Rutland's estates. The Lincoln Reds are grown more on the Lincolnshire border, and Flukes, a late potato but rather uncertain, as well as Farmer's Profits, have rather given way before Second Earlies and Irish Protestants. The last-named is a very good sort—prolific, mealy, and sizeable. There are good creesh or "red soil potatoes" at Knipton, but the

crack parishes for them are Braunston and Eaton, two or three miles south of Belvoir.

A great many turnips are grown on the clay of the Vale. Root crops also flourish well on the black soil of the Forest, and the swedes near Beaumanor have taken the Loughboro' Agricultural Society's prize. On the lighter, sandy soils about Peckleton and Kirby Mallory, capital swedes and Improved Skirvings are grown, but towards Stoke the land becomes stronger and less suited to them. At Cadeby, Osbaston, and Nailstone the sheep can eat them off the land, but not at Upton. About Narboro' and in the Harborough country they are never eaten off, but put down upon the grass. Very few are grown about South Croxton, which is not strong feeding, but strong working land, and hence the farmers very seldom finish off their beasts, but sell them as "Norfolk steers" between Michaelmas and December 8th.

Mangolds and cabbage have been introduced very largely since there was a failure in the turnip crop. This crop is nearly everywhere taken after wheat, and the land is dressed in autumn by some of the high farmers with twenty tons to the acre of farmyard manure, and sown in spring with three to five cwt. of salt according as the soil is strong or light, but on some farms three to four cwt. of guano per acre and some salt are deemed sufficient. The Yellow Globe has been very much run on, and so have the long reds on strong soils, as they grow more out of the ground and do not gather so much dirt—although they are, for this reason, more easily affected by the early frost.

Cabbages require as high farming as mangolds, and nitrate of soda and guano suit them best. It is found to be a very expensive and impoverishing crop, and generally follows wheat. The land requires to be very clean and well-manured, and we have heard of it getting in a very rare instance from 25 to 30 tons of farm-yard manure per acre. After such a dressing the crop is always eaten in the yards or on the grass. Under any circumstances, eating off cabbage makes great waste, and wherever it is practised only every third or fourth is left on the ground. Where the land is very strong, eating off is also objectionable for another reason—that the dead leaf and clay get into the sheep's feet and lame them. The drum-head cabbage, which is "all heart and no peel," is first-rate for teaching lambs, or feeding off cull ewes on the grass. From 45 to 60 tons have been grown per acre at Narboro' Woods in a good season; but they should be all consumed not later than November, as they are apt to open and crack with the wet weather. Lucerne is sometimes grown to the extent of two or three acres, for horses; but there is very little rape to be found in the county, and scarcely any mustard. Peas are sown to a considerable extent on the light soils; and are given, along with beans, to the hogs, which are thought by some farmers to acquire more bone and fibre on them than on any other food. Beans thrive on all the strong land, but are rather subject to blight on the lighter; very heavy crops of them are grown round Belvoir and Melton Mowbray, and the run is generally on the hardy and prolific Heligoland and white-eyed bean. About South Croxton and Billesdon the land does not suit them so well; but they are much cultivated, both in spring and autumn, about Six-Hills and Ragdale. Not many beans and peas are grown about Aahby-de-la-Zouch; and Berton-in-the-Beans is by no means superior in its growth to the parishes round it, whose farmers prefer peas, as the straw is more useful for stock.

Owston, Launde, and Tilton—which Jack Goddard and Frank Goddall know so well—are the big woods on the east side; but the great mass of the woodland is still upon Charnwood Forest, and, whenever owners plant

there, it is almost invariably with larch. Hollies flourish in rich luxuriance in the south—and more especially, to our eye, in the neighbourhood of Earl Shilton and Bosworth; while in Top Leicestershire the ash has been sown by winds or birds in almost every hedge. Woodmen tell you with pride of the ashes of Barton Field, and of the elms of Wistow. Between them, these two trees do yeomen service, as the ash supplies the felloes and the "hubs" of the wheels of those blue-and-red and straw-coloured four-horse waggons in which Leicestershire delights. One-horse carts are not nearly so much used as in Northamptonshire, and in hay and harvest-time they are hardly seen at all.

The woods, which are gradually being thinned, are generally a tangled mixture of oak and ash, with hazel undergrowth. In the detached ash-holts, the poles are shoots growing, for the most part, from old "stools," and generally seasonable and fit for cutting every 17 or 18 years. In *Viscount Hood v. Kendall*, which was tried a few years since at Leicester, it was found by the jury that there is a universal custom that such poles are not "crops," but belong to the landlord, in the absence of a special agreement. Leave was reserved to the defendant to move to enter a verdict, if the court above should be of opinion that, notwithstanding the custom, the defendant had a right to the poles; but, as it had not been left to the jury to consider on what terms the tenant held the farm, a new trial was ordered. The matter was, however, settled out of court. Such ash poles are very valuable for rails, the oaken posts for which are generally bought in Northamptonshire; those with three holes can be got for 8d., and those with four at 1s.

A good ox-fence consists of a flight of post and rails (for which wire is sometimes substituted); two yards from that, a four-foot hedge planted with quicks, and strongly back-fenced with maple, sallow, or blackthorn out of the woods, and then a wide ditch. Horses, resolutely ridden, will often clear from nine to ten yards over them. "I like the rail best," said an eminent huntsman to us, "on the other side of the hedge; so that, if the horse does not quite clear it, it will break if he drops on to it with his hind legs." They are generally strongest on the Harborough side, from Kibworth by Stanton Wyville, the Langtons, Hornyhold, and Hallston Bottoms. Some of the biggest bulfinches have been left for cattle shelter, and not cut for 30 or 40 years. For practical purposes they are useless at this stage, as, when they have once risen to 13 or 14 feet, there is little or no shelter at the bottom. About 10 or 13 years is the longest period to which they should be allowed to run, as they do not require so much putting down, and the old layers will use up again. The truth of the saying, "Good land, good fences," is patent from the bad growth of the quicks in the Six-Hills country. The little two and three acre fields with high hedges, round Dishley, are all gone; and in some parts the exigencies of steam-cultivation have also acted as a most potent hedge-grubber. About Normanton, where there is no "kettle o' steam," there has also been a great fall of hedge-row timber, and fields of 15 acres have been more than doubled. The only stone walls are on Charnwood Forest; but they are built very stiff, with sharp copings, which "cut a hunter's knees like a knife;" whereas, in Gloucestershire, "he can generally take a foot out of the wall, and no account." Wire-fencing, a yard off the hedge, has rather increased towards Pickwell and Leesthorpe; but the fox-hunting feeling of the country is against it, and the introduction of lease covenants to that effect, as well, have caused it to be pretty universally taken down during the hunting season.

Great strides have been made in drainage, and the results obtained by a very careful and scientific system at

Keythorpe have been already detailed in the Royal Agricultural Society's *Journal*.<sup>\*</sup> Thirty years ago a Leicestershire agriculturist was very strongly in favour of continuing to drain with straw in preference to tiles. His argument was to the effect that "draining with straw leaves pores in the clay, and thus leaves a possibility for water to get down; whereas if you put in a tile you put in clay on it again that soon becomes adhesive, and nothing gets through it." He did not then purpose going deeper than eighteen inches, and it was thought by many that water might percolate through two feet; but any one who proposed four feet was deemed ripe for the asylum. On some of the strong grass land two feet is still not exceeded, and is thought to keep the surface greener in a dry summer; but the conventional depth is from three to four feet, and ten or twelve yards apart in gravel and seven to ten in clay. A considerable amount of Government drainage has been done on large estates, at four feet with two-inch pipes, which have quite superseded the tiles set on slate. Clergymen have availed themselves of the loan pretty extensively for their glebes; and if the landlords take it up, they generally charge the tenant five per cent., and pay the one per cent. themselves. The Duke of Rutland and several of the landowners give the tiles, the tenants finding the labour; and this is in fact the pretty constant practice throughout the whole county.

And so from white and green crops—from oxen and woodland—we turn to stock at last. There is no lack of local show-stimulus, and "The Leicestershire and Rutlandshire Society," now "The Leicestershire and Waltham," was in being as far back as 1808. It did not seem to strike its committee, as it had done the apologists whom Arthur Young met on his way, that "ant-hills made a varied bite for the cattle." On the contrary, they offered a premium of 80gs. in that year to the man who "will free not less than five acres from ant-hills in one year; but still they made him wait "for proof of efficacy" three years for his money.

The Sparkenhoe Farmers' Club, whose lists are open to All England, is not, strictly speaking, a county institution, but selects its places of meeting from Staffordshire and Warwickshire as well. Its show is held early in September, and moves annually to one or another of nine towns. Agricultural labourers, single or married, framework knitters, farm-boys, and dairy-maids, all receive prizes, under certain well-considered restrictions. The skill of drainers and hedge-cutters is duly recognized, and, besides the general competition, there is a champion class among ploughmen "for the straightest ridge of two furrows." Rearing lambs is a science, which receives special attention, and the shepherd classes are quite distinct for long-wool, short-wool, and cross-bred flocks.

The store cattle judges are especially enjoined "not to take into consideration the present value for the butcher." Longhorn men regard the show as quite a rallying ground, on which they can still successfully give battle to their Teeswater supplinters. It is also as great an honour to be the Sparkenhoe cheese champion of the year as it is to get the highest price per ton at the Leicester October fair. The prizes, which amount to about £700, extend to pigeons, poultry, and rabbits, as well as barley for malting, fruits, and flowers. Conjointly with the two other societies, it has given a considerable impulse to poultry breeding in Leicestershire, where the Dorking is quite the prima-donna of the hen-roost.

The Loughboro' Society is conducted much on the same principle, and so is "The Leicester and Waltham," which holds its meeting in August, and is very liberally supported with special prizes, which swell its added money to about £850. The horse element is especially predomi-

nant. Hunter prizes are open to all England, and three are limited to six neighbouring hunts. A Scottish society makes fifteen hands the limits of its butter-milk cart horses, and fourteen-two of its sweet-milk cart ponies; and so in these Leicestershire lists a "cob" may not exceed the latter height, while a "hack" may range between it and fifteen-one. We know no higher standard of orthodoxy for country societies to follow.

Still there is none of that enthusiasm for breeding hunters with "great hips and rumps, and hocks a little in," which animated the breasts of "the old Blincoats." "Those crashers would hardly wait for hounds to get on the scent;" and they bred and rode such horses that Jonathan King, of Beeby, would hardly take one out of the stable to show a purchaser, under 300 gs. Many other farmers, who did not ride in this long blue coat and gilt-button brigade could sell to the Meltonians at £180 to £200; but very few hunters are bred now; and the days when Carver of Ingarsby could say that he got 300 gs. apiece for seven colts out of one mare seem to have faded into fable. Four-fifths of the Leicestershire hunters are now bought in London; and many of the rest are originally Irish colts, which have been brought over by the dealers to fairs at Leicester, Tamworth, and Belton (where Welsh pony buyers for the coal mines also resort), as well as the more finished material, which may be seen after a canter over "the forest" to the snug stables at Talbot-lane. If the farmers do use a blood sire, he is mostly put to a light waggon mare. Their choice of such sires is also very limited. They want another Vivalda, with his long, low, and lasting horses, which always, young or old, "had a leg to spare at a fence;" a Julius Caesar, with his fine tempered, up-standing, and "spawny bays; a Cannonball, with his good-looking, clever-actioned, middle-weight stock; and a Belsoni, with his big, plain browns, rather sour in the temper and forge-hammer in the head, and never quite ripe till they were rising eight. Cart-horse breeding is the safer aim of the Leicestershire men, when, as in some of the rich grazing farms, they do not grudge a colt his grass. A great number are sold at Waltham fair, on or about September 19th, where they usually come up, at two off. These Leicestershire colts are also in strong force, side by side with the kindred levies from Northamptonshire, Lincolnshire, and Notta, at the Rugby Martinmas fair, which lasts from the 15th to the 23rd of November. They are of all ages, from yearlings up to five years old, with a strong dash of the Clydesdale as well as the old Leicestershire horse in them, and mostly browns or blacks. The plough-farmers of Oxfordshire, Berks, and Bucks generally buy the juniors; and if there is anything with age and substance for dray-work, the London dealers seldom leave them.

March 2nd is the large spring fair at Leicester for store beasts, and there are also Low Fair and Palm Fair before and after Easter. Every Leicester Saturday is more or less a fair up to Old May-day. April 2nd is also a large fair-day at Lutterworth, and so is Holy Thursday. Market Harborough has a very large one in October, and the "Norfolk Steer Market" is held at Leicester on December 8th. From March to June the Shropshire, Hereford, Welsh, and Irish cattle are poured into the county through Leicester market, and again from September to December.

The Hereford still holds the lead of its kinsman, the black with white face Shropshire, and the Welsh runt, but there has been no Hereford dairy in the county since Mr. Henry Chamberlayne of Desford died in '53. He bore an honoured name in Smithfield Club annals, and besides acting as steward, he added to his head prize for a Hereford bullock in '38 the gold medals of 1838-39 for Long-woolled wethers, with Leicesters bred from his

<sup>\*</sup> Vol. xiv. p. 96.

own ewes, and two of them by Buckley rams. Herefords have always been liked in Leicestershire, not only for their feeding qualities, but for their fine tempers in the yards, where the horns of the West Highlanders are never at rest. The Shropshire was once upon a time more of a smoky-faced brindle, until he was "crossed up" about Pontypool and Welshpool, with the Welsh and Hereford cattle, and took to the coat of the one and the face of the other. Still his ancestry will hardly repay inquiry, and no doubt has much in common with the Montgomeryshire and Glamorganshire breeds, both of which are nearly extinct. The former of these two was once very common in Shropshire, and in many points, except its superior size, resembled a Devon; while the latter, with the substitution of black for red, was very like a Hereford in its colour marks. Be their pedigree what it may, the Shropshire, like the Runts, are good ones to rough it, and when there is not room to tie up all, they have to lie in the yards. A few West Highlanders, Devons, and Galloways are still to be seen; but that once great Scotch fair at Melton Mowbray in August, where "the heavy blacks" from the Stewartry might be found in droves, now knows them no more; and "The Shamrock" has quite superseded The Thistle. The heaviest cattle supplies are sent up to Smithfield between July and December, and in a straggling way during the first half of the year. There are not many cows and heifers amongst them; but any shortcoming in this respect is made up by the bullocks. Still there is no doubt that the Leicestershire farmers stock hard, and one season with another send off beasts quicker than they once did, and not so ripe in condition; and in a Top Leicestershire 400-acre farm a grazier will have about 150 beasts and 600 sheep.

The longhorns still struggle for a separate existence in a small district round the point of impact of Warwickshire, Derbyshire, Staffordshire, and Leicestershire. They had made themselves a name at Upton as far back as 1745; but it was not until 1756 that the blood of the renowned Twepeany, from Dishley, began to tell, and caused Bakewell to speak of George Chapman's as "*one of the best herds I know anywhere.*" Some years after Bakewell's death, Shakespeare of the sort made £430 at Mr. Prinsipp's, of Croxall's sale; and it was said that 700gs. was refused for Tiger. With such traditions to inspire them, we can hardly wonder at a select few "clinging to this expiring cause" with more than Jacobite zeal. The Upton herd has an uninterrupted title of more than eleven times eleven years, in grandsire, sire, and grandson. The present Mr. Chapman has taken seven firsts and a second with them at Smithfield, and five firsts and as many seconds at Birmingham, besides breeding three other winners. Competition at these shows is always very limited; but his steer of 8 years and 8 months, which took double Christmas honours in '63, won the Sparkenhoe county cup in the same year, against two longhorns and three shorthorns. Mr. Chapman has also taken £70 in Royal Agricultural prizes at Exeter, Windsor, Battersea, and Plymouth. Among his champions were "Exeter," with his shaven poll and great brindled carcass, which weighed 91st. 12lbs. per quarter, and "Sparkenhoe," that "grand old longhorn bull, himself one of the greatest curiosities of the show," who journeyed still farther west in '65.† Mr. Godfrey, of

Wigston Parva (who won with a pair of cows, when the Royal Agricultural Society met at Warwick), and the Messrs. Taverner, of Upton, have also longhorn dairies in Leicestershire; but Mr. Green's and Mr. Astley's of Odstone herds were dispersed when their owners died.

The adherents of the breed muster twelve or thirteen more in the three adjoining counties; but a few of them are not purely longhorn men; and one of them, Colonel Inge, keeps a shorthorn bull. They give as the reason of their faith in beasts of the sort, that they are not only hardier, and keep their young looks longer, but furnish more meat on the best parts, and a greater weight of carcass at a less outlay. The cows, which should calve, if possible, at three years old, feed fastest from that age to five, especially if they have had a calf. Their tendency is to feed more on the back and barrel; and hence the butchers are rather prejudiced against them, and say that they have not enough of the steel-yard inside, and do not "prove" so well in consequence. Many of the cows will hold on well to fifteen, and then feed up to eleven or twelve score a quarter. A yearling bull will make from 15 gs. to 25gs., and some years ago a two-year-old was sold by auction for 50 gs.

Mr. Burbury has bred them white, but the darker colours are preferred. Dark brindle is thought very hardy; but Mr. Chapman and some other breeders like cherry-red, with the back white, and the sides coloured. The coat should be as curly as possible; and a face with a darker shade intermixed is liked better than a white or bald. They are a remarkably docile race, and their thick skin saves them in a great measure from the torture of the gadfly. The tanners set much store by it, and will pay as high as £2 7s. 6d. for a first-rate bull's hide, and still higher for that of an ox. Good keep gives that blood-red tinge to the horns, which is always prized by a breeder. They begin to show the age wrinkle after three, and run into all shapes. Some grow so much down that the cows can hardly graze, and they require to be sawn off, like "the wheel-horn," which will curl right back into the nose. Others go straight away into space, at an acute angle; and it is not very uncommon to see one following the usual curve, and the other curled into the "scorp," like a boxer's hands in position. To walk down the massive red-and-white line of forty cows at Upton, all busy with their hay bundles on the pastures, and the thirteen-year old "Rose" still "blooming fresh and fair" at their head, is a very pleasant picture, even on a January day, backed up, as it is, by Bosworth Field, whose well still marks the spot where the third Richard lost his life and crown.

As a general rule the plainest cows are the best milkers, and the milk of a seven or eight year old one is generally thought the richest. Some of the best "fill-pails" will give 19 quarts at two meals, and the dairy farmers have made 4½ cwt. of cheese from one cow. They are kept in winter on barley straw and pulped turnips, and mostly calve early in April. Calves get new milk for three weeks or a month, and then have linseed and oilcake dissolved in gruel, with the over-night's milk or whey. The cows are good nurses; and one of Mr. Chapman's, which had only three teats, brought up a bull-calf on each with credit. Some of them have been sold recently to Mountserratt, as well as to Ireland. They are crossed with Shorthorns to a small extent in the county, and the "half-horns," as they are called, milk well and come to a great weight, if they are not taken beyond a first cross.

H. H. D.

\* Report of stock stewards at Plymouth, Royal Agricultural Society's Journal, vol. i. (S.S.), p. 364.

† Mr. Chapman's most recent purchase of new blood has been from Mr. Fletcher Riggs, of Wythop, in Cumberland. This is going back to first principles, as the Drakelow stock of Sir R. Grosley, on which Mr. Webster, of Canley, near Coventry, the first scientific improver of the sort, is said to have worked, was kept up by bulls from that county and Westmoreland.

## THE ESSEX AGRICULTURAL ASSOCIATION.

## MEETING AT CHELMSFORD.

In the exercise of a certain timidity, or still more certain selfishness, the show of the Essex Agricultural Association is still mainly confined to the county. In this respect it does not rank well with its neighbours; and any further comparison would be as unfavourable, for despite the admirable way in which the old "Royal" ground was laid out, the meeting was at most but a partial success. The cart-horses were with a few exceptions so indifferent, that a well-known breeder and judge, who has so far voted for a continuance of the home-trade in prizes, declared that he could support such a system no longer; while Messrs. Newton and Little very candidly expressed their surprise at the sheep and pigs, and at having come so far to see so little. On the other hand, notwithstanding the absence from the lists of such supporters as Messrs. Marjoribanks, Bramston, and Clayden, who have lately been selling out, the entries of Shorthorns were very creditable; as a good word may be certainly said for the general strength of the riding-horse section. Then, again, the town and district took up the visit with a deal of heart. In association with the Association there were flower-shows, poultry-shows, and dog-shows; flags were flying and shops were closing; as in fact there was plenty of spirit evinced everywhere, save just where spirit should have been most prominently displayed. Let the entries be thrown open, as they are in Norfolk and Suffolk, and let any animal be allowed to win, so long as he is good enough to do so; and then, and not till then, Essex, as we have just said, may take rank with its neighbours.

As it is, and but for the offer of a few All-England premiums, the proceedings have of course little beyond a merely local interest and influence. After looking through the sheep, the judges came to look still harder at their instructions, which went to say they were "not to award any prize in classes in which the animals exhibited did not possess sufficient merit." Here was clearly a dilemma on the face of it, for the entries were but few; some of these were not sent, and those that were had but little merit. If the Essex Society be still to continue a "limited" company, it is a question of some moment whether these excellent instructions should not be amended, or more properly altered? Or, by another meeting the prize list may itself read in significant commentary on this restrictive principle. However, Lord Braybrooke was permitted to take the premiums for Southdowns against absolutely no competition. The Audley End sheep show a deal of breeding; but the rams, more especially, are small, light of wool, and anything but good in their symmetry, beginning with snake heads and weak necks. The ewes and fat shearlings were better; but even these did not come up to the character of the Smithfield Club prize pen. Mr. Giblin had it almost as much his own way with the Cotswolds and Oxford Downs; but these would make no mark out of the county, and so Mr. Hugh Aylmer of course took the open prize for long-wools with a small but useful sheep of very superior quality to anything of home-growth. In the other short-wools, Mr. Portway won with some coarse useful black-faces; but these sheep are so plain, that they can never tell in the show-yard, while in charity to some of the other exhibitors of other short-wools, we will say nothing more about them. The judges had the

wooden spoon ready for one pen of ewes and lambs, as "the worst lot seen in a show-yard for a very long time." By the way, would it not be as well at a limited county meeting to have a wooden spoon for the worst lot in every class, as inducement for doing better? On this showing, the sheep judges would at any rate have had something to do at Chelmsford.

Of pigs there was a very short entry; but we have before now spoken to the merits of Mr. Griggs' Berkshires, as really good specimens of their sort, and now crossed, as the boars are bred from Captain Stewart of Gloucester. Still they could make no stand in the All-England classes, where the Sextons could not and Mr. Stearn would not show, and so as at Downham the Duckerings and Mr. Crisp had it all their own way, with Lincoln for large and Suffolk for small, as usual.

It may be as well to have it known that the horror of one of the Shorthorn judges—and two of the three were "Royal" authorities—is "a pretty bull." And as Lady Pigot sent a pretty bull in the well-named Charles le Beau for the All-England premium, her ladyship reached but a high commendation, and Mr. Christie kept the prize in the county with Duke of Grafton, by Duke of Geneva, bred by Lord Penrhyn, a big, long, broad four-year-old, of good quality and with some capital points, being especially good in his back and hind quarters, and well let down to his hocks. Against all this, he is light in his neck, and has a rather tapering egg-sucking head, but is nevertheless at all points a grand useful bull, that might have commanded some notice at Leicester, had his owner hardened his heart to send him on. He could not take the first prize class of the county here, because he took it at the show in 1867; but the judges held to his line so far as they could. They made his daughter Potentilla their choice in the youngest class of heifers, and then took her with her father and mother as the best family party, or bull, cow, and calf; the cow Primula having previously won prizes at all stages from a heifer calf upwards at these meetings. The first prize bull of the county, Mr. Upson's Sorcerer, is a good well-grown three-year-old, also bred by Lord Penrhyn, and a long way the best of a short class. There was nothing very extraordinary amongst the two-year-old and yearling bulls, Colonel Brice in the younger class fairly beating Mr. Sturgeon's good-looking one on the nice points of hair, hand, and quality. In a better lot of cows, over which some commendations were scattered, Mr. Upson was again first with a fine taking cow in high condition, the second being weak in her loin, but showing a deal of breeding. The best two-year-old heifer was in anything but show form, having recently calved, and being very poor, so that all due allowance had to be made for her by "judges"; while they got on again to the Duke of Grafton vein in his daughter Patchouli 4th, a well-grown handsome yearling, of good colour and quality; Mr. Pigot getting next with another very nice heifer in Dagmar. Another daughter of the Duke, as we have already mentioned, was the best heifer calf; but the trio of judges got terribly at variance for a second, each taking and holding to his own, until Mr. Aylmer had to be called in, when he went with Mr. Garne for Ringlet, another daughter of the Duke of Grafton, a son of whose was also the best bull-calf. Amongst the Shorthorns without pedigrees Mr. Upson

took the prize for heifers under twelve months old, with one that for style and quality showed a deal better than many to be found in *The Herd Book*, as it appears, she is bred at least on side of her head; whilst far among the best dairy cows was a beautiful Alderney exhibited by Mr. Beadel; but the judges kindly took it into consideration that she would be worth little or nothing when she had done with the dairy, and so they highly commended her, and gave the two prizes to two Shorthorns. As Shorthorn men they no doubt did quite right; but as the class was distinctly one for dairy cows they no doubt did quite wrong, as their unfortunate explanation only goes to make this wrong the greater.

As we stated in our last, Mr. Thompson, the single-handed judge and his own veterinarian, passed Harwich Emperor at Downham, and Professor Varnell passed him again at Chelmsford, although the horse had previously been disqualified by some of the profession. He accordingly stood in again for the All-England Cup, over which award there was a deal of deliberation; but eventually Cup-bearer was once more proclaimed the winner, as he was at Braintree in 1867 and at Epping in 1866, Mr. Manning still clearly holding to his horse, who has gone on improving, and whose two "odd" forelegs did not show so conspicuously as they have done. Harwich Emperor, like his father before him, "seems" to be flat in his sides after work; and the third left in, Mr. Wilson's President, beat Cup-bearer for the Cup at Fakenham last year. They are three very good horses, and settled as the points of a Suffolk may be supposed to be, the three may as likely as not change about again the next time they meet, the more so as only one of the three judges at Chelmsford is a breeder of the sort. President won another All-England premium, in which neither Cup-bearer nor Emperor showed against him; his chief opponent being a two-year-old of Mr. Bott's, a very smart good-limbed colt, that was not only the best of the county two-year-old class, but first again against All-England of the same age, where he beat a very good class, many of the entries being Suffolks born and bred. Mr. Wolton's well-known Violet was the best All-England mare, and Major Wilson's three-year-old the best filly, and with these the excellence of the cart-horse section came to something like a full stop. For the cart stallions of the county there were two premiums and two entries, the first prize going to a dead lame one and only half a good one; the second with more propriety being withheld from an animal, that any man might have the misfortune to breed, but no one as we should have thought the temerity to buy. However, the Reverend R. A. Westhorp duly enters his horse as bred by Mr. Crisp, and Mr. Crisp is congratulated accordingly. The county cart mares were an indifferent lot; but Mr. Holmes' prize mare and foal were worthy of their place and price, 50 gs. for the lot. There was only one three-year-old filly, and she was a bad one; but we must make some exception for Mr. Bott's couple of two-year-old fillies, like his two-year-old colt by Chapion and both of very good quality. The yearlings were few and poor, and the foals in much the same category, the best being out of the prize mare. Almost all the cart-horses exhibited were Suffolks or Suffolk crosses, the majority of course chesnutes, with a few bays by way of variety; but beyond Mr. Bott's entries, the county of Essex had very little to do with the actual merit of this department. Indeed, if this limitation and disqualification after winning be only persevered in, the probable result will be that animals competent to win in Essex will be incompetent to win anywhere else.

The riding-horses were a deal better, and some very decided improvement is here discernible, no little of which is attributable to the desire of Sir Thomas Lennard to get and keep some good blood in the country. For years

past there has always been a thoroughbred stallion within the farmers' reach at Belhus; but Sir Thomas offers some further inducement, in the shape of premiums for stock by his horses. Mainstone now appears to be replaced by Amsterdam, a neater horse of very high quality, and with all the prestige of performance to recommend him. He was quite the hero of the day at Chelmsford, taking the premium in the county class against three or four very well-bred but odd looking horses, that as thoroughbred sires seem to have been turned to queer purposes. The excuse made for Whitmore, a West Australian horse, looking so bad, was that he had been driven about by his owner in a cart; while Port Royal by Yellow Jack was ready to be "jumped" as a hunter, and Camillus by Newcourt looked more like steeple-chasing than the stud. But the judges resolutely scorned from the first having anything to do with the "leaps" in front of the Grand Stand, either in the way of proving a sire or his stock, so that Amsterdam's looks and action secured him a very bloodless victory. In the All-England class the contest was closer, with four or five fresh animals in, such as the lumbering Abbot, the lucky Knight Templar, that has already won a prize in Essex; a Big Ben four-year-old of Captain Sparrow's, and another four-year-old from Hasketon, a stud that has taken so many All-England honours out of Essex into Suffolk. Still King of the Dale, despite his size, failed to accomplish so much, the premium again going to Amsterdam, to the very manifest satisfaction of the public, but in the ring the award was only arrived at on a division. Although a showy young horse, King of the Dale does not prove so well; he is high on his leg, has not the best of shoulders, is thrifty in the setting on of his head, and will have to fine and drop a bit before he can do better than he did at Chelmsford. In another open class for "stallions, thorough-bred or otherwise, calculated to get weight-carrying hunters," of course he won against such cattle as Pollard, not thorough-bred; Harkaway by Master Moody; Morgan Lightfoot, a machner, that took a prize in another class, although nobody knows what for; Young Kingston, beaten by Morgan Lightfoot, and that is saying something; and The Abbot, Port Royal, and Whitmore, over and over again. But Captain Barlow had his reward in other ways, for in the best class in the show, where everything was commended, much of the superiority was traceable to his stable. This was the lot of two-year-olds, in which Mr. Vickerman was first with a handsome, well-grown, very promising, thorough-bred filly by Ace of Clubs, and highly commended for another filly by Surplice; while another high commendation, and "the reserve" went to Captain Sparrow's filly by Ace of Clubs, for which the judges regretted they had not a second prize at their disposal. Some of the young Mainstones, both foals and yearlings, were full of promise; and the two prize brood-mares had foals at foot by this horse. Of the younger stock, the three-year-olds, on the contrary, were very indifferent, and there was nothing but the winner in it; while being without further condition, and open to hunting hackneys, or coaching colts or fillies these classes were made up of "all sorts," although the best bred one generally got it. A nisch level mare of Mr. Christy, that promises to go over a country, was the best four-year-old; but there was no standing against Mr. Barker's long string in the hunters of all ages. Barring another of Mr. Christy's he had not much to beat amongst the mares; while the steeplechase horse Tom Bowline was a deal too much of a workman at all points to give the geldings a chance, and he won the open prize almost as easily. Mr. Beadel's prize hack-mare and prize cob were both very good of their kind, the cob Jacob being a treasure for a "heavy-weight." Mr. Christy had also a very neat hack-mare, and Mr. Hicks a wonder-

fully clever dun pony, that for shape, style, and "carriage" was a long way ahead of his motley company.

There was a goodly array of implement stands, which, as somebody said, went to "make it look like little Royal;" but with neither trials, premiums, nor novelties our report would come chiefly to a list of exhibitors for the home and the adjoining county of Suffolk. The flower-show was said to be a success, as it certainly appeared to be well-attended; but there was not a crowded company at the dinner, where the chief topic amongst the M.P.'s of both sides was the new Foreign Cattle Market. Mr. Spooner, as the only one present, returned thanks for the judges, and in doing so took the opportunity of very fairly ridiculing the practice of "some other societies," where catalogues containing the merits of the animals and the names of the owners are placed in the judges' hands. The only society we know of, that adopts this plan, is the London Horse-show Society, while Mr. Spooner acted "in happy ignorance of all this," and, as it appeared was applauded, and not hooted.

## PRIZE LIST.

### JUDGES.

**CART HORSES.**—T. King, Preston Hall, Suffolk; J. Manning, Oringbury, Wellingborough; W. C. Spooner, Ealing House, Southampton.

**RIDING HORSES.**—H. Biddell, Playford, Suffolk; H. Corbet, Strand, London; H. Thurnall, Royston.

**CATTLE.**—W. H. Beauford, Bedford; G. Garne, Church-hill Heath, Chipping Norton; W. Ladds, Ellington, Kimbolton.

**SHEEP AND PIGS.**—M. Biddell, Playford; E. Little, Chippenham; B. Newton, Campfield, Woodstock.

**VETERINARY INSPECTOR.**—Professor Varnell, Beech House, Belton, Yarmouth.

### HORSES FOR AGRICULTURAL PURPOSES.

**Stallion.**—First prize, £20, G. D. Badham, Bulmer Tye, Sudbury (Great Eastern); second, £10, withheld: no merit.

**Entire two-year-old colt.**—First prize, £15, W. Bott, Broomfield (Champion); second, £7, G. D. Badham (Fitz Emperor); highly commended, R. G. Salmon, Clacton Hall (Major); commended, H. Croxton, Burnham (Young Boxer), and Marriage and Sons, Broomfield.

**Mare, not under four years.**—First prize, £8, A. B. Croxton, Burnham (Silver); second, £4, E. Catchpool, Feering Bury.

**Mare, four years and upwards (open to all England).**—Prize £10, S. Wolton, jun., Kesgrave (Violet); highly commended, A. B. Croxton (Silver); commended, F. M. Wilson, Stowlangtoft Hall, Bury.

**Mare, with foal at foot.**—First prize, £10, H. Holmes, Boeking; second, £5, W. Belcher, Sandon (Blossom).

**Cart filly, under four years.**—Prize, £10, F. M. Wilson; highly commended, F. M. Wilson; commended, S. Wolton, jun. (Matchett).

**Three-year-old filly.**—Prize, £5, T. Taylor, Earls Colne.

**Gelding.**—Prize, £5, G. Potter, Hoo Hall, Rivenhall.

**Two-year-old filly.**—First prize, £7, W. Bott; second, £4, W. Bott.

**Yearling colt.**—First prize, £5, J. Gibling, Little Bardfield; second, £3, G. Norfolk, Layer Marney.

**Yearling filly.**—First prize, £5, H. Foster, Totham; second prize withheld: no merit.

**Foal.**—First prize, £5, H. Holmes (out of prize mare); second, £3, T. Taylor; commended, W. Elphick.

**Plough horses.**—First prize, £7, G. F. Josing, Berners Roding (Gilbert, Diamond); second, £3, withheld.

**Stallion (open).**—Prize, £25, W. Wilson, Bayham Hall, Ipswich (President); highly commended, W. Bott (Champion).

**Stallion (open to all England).**—Prize, £20, T. Crisp, Badley (Cupbearer); highly commended, W. Wilson (President), and I. Rist, Tattingstone (Harwich Emperor); commended, C. Boby (Conqueror).

**Colt (open).**—Prize, £10, W. Bott (Champion); highly commended, W. Wilson and C. Boby (Captain).

### RIDING AND COACHING HORSES.

**Thoroughbred stallion.**—Prize, £15, Sir T. Barrett-Lennard, Belhus, Romford (Amsterdam).

**Stallion, not thoroughbred.**—Prize, £10, F. Butcher, Colne Engaine (Morgan Lightfoot).

**Hunting mare.**—Prize, £7, F. Barker, Ingatstone (Jessica).

**Hunting gelding.**—Prize, £7, F. Barker (Tom Bowline).

**Hunter (all England).**—Prize, £20, F. Barker (Tom Bowline); highly commended, B. Sparrow, and J. Grout (Turk); commended, J. Christy (Madonna).

**Hackney mare.**—First prize, £5, W. J. Beadel, Chelmsford (Duplicate); second, £3, J. Christy (The Nun).

**Hackney gelding.**—Prize, £5, P. O. Papillon, Lexden Manor.

**Mare or gelding, 4 yrs.**—Prize, £7, J. Christy, Roxwell (Madonna).

**Mare or gelding, 3 yrs.**—Prize, £7, G. D. Badham (Eclipse).

**Mare or gelding, 2 yrs.**—C. R. Vickerman, Thoby Priory, Brentwood (The Countess); highly commended, C. R. Vickerman (Crucifix), and B. Sparrow. The class commended.

**Mare and foal.**—First prize, £6, J. Cassidy; second, £3, G. Pool.

**Cob.**—Prize, £5, W. J. Beadel (Jacob); commended, Alfred Hockley, Hatfield Broad Oak, W. Lucking (Young Fireway), and Sir J. T. Tyrell, Bart., Boreham-house.

**Pony.**—First prize, £4, C. Hicks, jun., Stansted Mountfitchet (The Earl); second, £2, C. Barnard, Harlow.

**Half-bred yearling by Mainstone.**—Prize, £5, C. Sturgeon, South Ockendon-hall.

**Thorough-bred stallion (open to all England).**—Prize, £25, Sir T. Barrett-Lennard (Amsterdam).

**Stallion, thorough-bred or otherwise, to get hunters (open).**—Prize, £25, Captain F. Barlow (King of the Dale).

### CATTLE.

**Shorthorn bull.**—First prize, £15, J. Upton, Rivenhall (Sorcerer); second, £10, J. Piggot, Beckingham Hall (Grand Visier).

**Two-year-old bull.**—First prize, £10, A. P. Clear, Maldon (Monarch); second, £6, J. Chaplin, Ridgwell (Raven's Eye).

**Yearling bull.**—First prize, £10, Col. Brise, Spain's Hall (Whipper-in); second, £6, C. Sturgeon (Grand Signeur).

**Cow.**—First prize, £10, J. Upton (Violet 3rd); second, £6, J. A. Piggot (Daphne); highly commended, J. R. Chaplin (Iona).

**Heifer (two-years-old).**—First prize, £8, J. Upton (Rosebud); second, £5, J. R. Chaplin.

**Yearling heifer.**—First prize, £7, J. Christy, jun. (Patchouli 4th); second, £5, J. A. Piggot (Dagmar).

**Heifer, not exceeding 12 months old.**—First prize, £6, J. Christy, jun., Boynton Hall (Potentilla); second, £3, William Tippler, Roxwell (Ringlet).

**Bull, not exceeding 12 months old.**—First prize, £6, J. Christy, jun. (Duke of Babraham); second, £3, J. Hutey, Rivenhall.

**Shorthorn bull (open to all England).**—Prize, £20, J. Christy, jun., Boynton Hall (Duke of Grafton); highly commended, H. Aylmer, West Dereham Abbey, Norfolk (Thorndale Duke), and Lady Pigot, Branches Park, Newmarket (Charles Le Beau).

**Bull, cow, and calf (open to all England).**—£20, J. Christy, jun. (Duke of Grafton, Primula, and Potentilla).

### SHORTHORNS WITHOUT PEDIGREES.

**Cow.**—First prize, £8, W. Sworder, Stapleford (Tawney); second, £4, D. Christy, Patching Hall.

**Heifer, two years old.**—First prize, £5, J. Oxley Parker, Woodham Mortimer-place; second, £3, Colonel Brise, Spain's Hall, Braintree.

**Yearling heifer.**—First prize, £5, J. Giblin, Little Bardfield; second, £3, J. Oxley Parker.

**Heifer, not exceeding 12 months old.**—Prize, £3, J. Upton, Rivenhall.

### OTHER PURE BREEDS.

**Bull.**—Prize, £5, C. Hill, Harrow Lodge, Hornechurch.

**Bull, two years.**—No entry.

**Cow.**—Prize, £4, S. Hanbury, Wickham-place, Witham (Alderney).

**Heifer, two years old.**—Prize, £3, C. Hill (Quennie).

**Yearling heifer.**—Prize, £3, S. Courtall, Gosfield, (Alderney).

## DAIRY CATTLE.

Cow or heifer.—First prize, £8, J. Upson, Rivenhall (Lady Dacie End); second, £5, S. Young, jun., Roxwell (Shornhorn); highly commended, W. J. Beadel (Alderney).

## FAT CATTLE.

Ox or steer.—Prize, £5, J. S. Dennia, Maashbury Hall (Shorthorn).

Cow or heifer.—Prize £5, J. Perry, Bocking (cow).

## SHEEP.

Southdown ram of any age.—Prize £6, Lord Braybrooke, Andley End.

Short-wooled ram.—Prize £5, J. M. Green, Stradishall, Newmarket (blackfaced).

Cotswold ram.—First prize £5, J. Giblin, Lt. Bardfield; second £3, J. Giblin.

Long-wooled ram.—First prize £5, W. King, Woodham Ferris (Lincoln); second £3, W. King (Lincoln).

Oxfordshire or Shropshire ram.—First prize £5, J. Giblin (Oxford Down); second £3, J. Giblin (Oxford Down).

Shearling Southdown ram.—First prize £5, Lord Braybrooke; second £3, Lord Braybrooke.

Shearling shortwool ram (any other breed).—First prize £5.—J. M. Green (blackfaced); second £3, J. M. Green.

Shearling Oxfordshire or Shropshire ram.—First prize £5, J. Giblin; second £3, J. Giblin.

Shearling long-wooled ram.—First prize £5, J. Giblin; second £3, J. Giblin.

Shearling pure Down ewes.—First prize £6, Lord Braybrooke.

Shearling short-wooled ewes.—First prize £5, W. Sworder; second £3, P. Portway.

Shearling long-wooled ewes.—First prize £5, J. Giblin.

Ewes and lambs.—First prize £5.—J. Giblin (Cotswold); second £3, C. Sturgeon.

Fat shearling short-wooled wethers.—First prize £5, Lord Braybrooke; second £3, Lord Braybrooke.

Fat shearling cross-bred or long-wooled wethers.—No entry.

Long-wooled ram.—(Open to all England).—Prize £10, H. Aylmer, West Dereham Abbey (Norfolk Cotswold); commended, J. Giblin (Cotswold).

Short-wooled ram.—(Open to all England).—Prize £10, Lord Braybrooke (Southdown).

## PIGS.

Boar.—First prize £5, J. Pertwee, Boreham (small Suffolk); second £3, Wm. Thompson, jun., Thorpe (Essex).

Boar, not exceeding 12 months.—First prize £5, G. D. Badham (white); second £3, G. Griggs (Berkshire).

Sow in pig.—First prize £5, G. Griggs (Berkshire); second £3, C. Sturgeon (Berkshire).

Sow and pigs.—Prize £5, G. Griggs (Berkshire).

Three sow pigs.—First prize £5, J. Giblin; second £3, G. Griggs; commended, C. Sturgeon.

Boar, large breed.—(Open to all England).—Prize £10, Duckering and Sons, Northorpe, Kirton Lindsey (Victor).

Boar, small breed.—(Open to all England).—Prize £10, T. Crisp (small white); highly commended, Duckering and Sons (Comet).

Sow.—(Open to all England).—Prize £5, Duckering and Sons (Lily); highly commended, Duckering and Sons (Primrose).

## THE DINNER.

The dinner took place on the Thursday, but the attendance was not so large as usual. The President of the Society for the year, Sir C. C. SMITH, Bart., who occupied the chair, gave "Success to the Society." Their presence, he said, indicated the interest they took in the society, which had now been organized eleven years. At that time it was thought a bold experiment, but he thought he might say it had now lived down all mistrust and doubt, and an evidence of its validity was the extension of the meeting to two days. This might be a bold, but he considered it a very wise, step, and thought it would result in success. The president then congratulated the members upon the successful character of the meeting, upon the improvement in both the numbers and quality of the stock, and upon the general fact that the society was

making a gradual but certain progress. Implements also were well represented, and in these days, when the want of labour was so much felt upon farms, he thought they could not do better than encourage and acknowledge the merits of the machinery which was so efficient a substitute. He especially noticed the tube well, and recognized in that invention a great boon to the labouring man upon a farm; and with regard to the produce exhibited from Barking, he said they could but rejoice rather than frown at the advent of the odorous fluid which enabled cultivation to be brought to so high a state of perfection. In conclusion, he acknowledged the debt of gratitude that was due from those to the secretary of the society—(Hear, hear)—and all those who had assisted to promote the welfare of the society.

Mr. W. C. SPOONER, who returned thanks for the judges, said, in reference to the particular department in which he had acted that day, he was happy to say that, coming from a long distance, he was not aware of the ownership of a single animal that came before him, for the society very wisely did not do as he had heard some societies did—put into the judges' hands catalogues containing the merits of the animals and the names of the owners (laughter). In happy ignorance of all this, they were enabled to give their judgments impartially and to the best of their ability. On behalf of the judges, he congratulated the society upon their very excellent show, and the large number of animals exhibited. In the department in which he had been engaged—that of the cart-horses—there was a want of competition in two most important classes. One of these was the class of stallions, in which there were only two animals exhibited, and only one possessed any merit. In mares also there was a want of competition and a want of merit. He suggested to the committee whether, in order to remedy this state of things, they should not give some greater encouragement to exhibitors, and take away some of the present restrictions.

Sir THOMAS WESTERN, in responding for the County Members, said the show had an additional attraction for him, because of the past devastation caused by the cattle plague, and the present absence of that pestilence from the country. This subject reminded him of the Metropolitan Foreign Cattle Market Bill, upon which, he said, there would be a severe fight in the House of Commons. He was not prepared to say that it would be carried, but it was a very important measure for this country, and the exertions of all were needed to pass it. Many members connected with large towns were opposed to it, because they believed it would be the means of contracting the supply of meat; but that was not so—the only idea in the minds of the promoters of the Bill was protection to the home cattle against the re-introduction of the cattle plague. It would be brought forward in a few days, when he trusted it would have the support of every member of this county, and of the borough members also; and he hoped to be able, when they met again next year, to hear that the effects of the Bill had been such as they desired.

Mr. SELWIN-IBBETSON, in responding, also alluded to the subject of the Metropolitan Foreign Cattle Markets Bill, and said he himself felt very great interest in the subject, he having sat upon the Committee on the Bill for 25 days, during which time they had had a mass of evidence before them, and which had been sifted, not by the most impartial adversaries, but by men who used every possible device to defeat the measure. The Bill, notwithstanding, had gone to the House, not exactly, perhaps, as its friend could have wished; but till a very serviceable measure. When it came before the House he was satisfied that a large number of agricultural members of Ireland and Scotland, who did not sit on the same side of the House as himself, would give it their support. It was said by the opponents of the measure that it would diminish the supply of foreign meat; but every witness the Committee had before them told them that, though at first the restrictions of the measure might to a certain extent impede importation, the trade would almost immediately find its own level. The farmers throughout England, and certainly of Essex, ought to look upon this measure as one most important to their interests.

Lord EUSTACE CECIL said: With regard to the measure before Parliament which had been alluded to, he need not say that he thoroughly went with the two previous speakers in all that they had said. He hoped the Bill would be made to suit, if possible, all classes, but especially the agricultural community. Without going into several agricultural objects which had been be-

fore the House, and which, perhaps, might be considered semi-political, there was one exception to which he might allude, and that was a very old friend with whom he had lately had a great deal to do: he alluded to the Malt-tax. He read the other day that at a certain meeting, of a rather more political character than this, some one who uttered the well-known cry upon this subject was threatened to be turned out of the room. He had, therefore, an additional reason for asking for their indulgence in bringing this question before them, because he certainly had no desire that so rigorous a measure should be carried out as regarded himself—that he should be turned out of this room or elsewhere. As a member, however, of the Malt-tax Committee, he felt it was only right to report progress upon the question, because a great deal had been said in

Chambers of Agriculture and elsewhere of the dilatoriness of that Committee. The fact was that they had had a great many disadvantages to contend against: they had had a number of witnesses who had not given their evidence in the shortest way in the world, and their worthy Chairman—small blame to him—had thought fit to get married, and no one could grudge him his well-earned honeymoon. They, however, he thought, began to see the end of their discussions; and he sincerely hoped that their deliberations would be satisfactory to the public, and to the large agricultural class. Two things he had especially learned while on that Committee—one was that everybody was most anxious to get rid of the Malt-tax, and secondly, that no one would allow his own trade or profession to be agood one.

## THE BIRMINGHAM HORSE AND HOUND SHOW.

### IN BINGLEY HALL.

"Love me love my dog," is an old saying, that had it been started in these days there would most likely have been added "and give him a prize." This is equally applicable to the horse, and we know of no more unenviable post than a judge at a show; as for one he pleases there are ten non-contents. But this is a mere matter of arithmetic after all, the old sow and her pigs again, and more pigs than teats. If there is one more unenviable post than that of a judge it is the critic, who goes to the best of his ability as straight as the crow flies, for he may not only offend the exhibitors, but the judges as well. And why has Ginger turned that smile of honey that he was wont to greet us with into one as sour as verjuice, and growl as he passes, "His head arn't well set on, arn't it? And where, oh where is the hearty shake of that horny hand of old Whipcord as he looked in our eyes? we imagined to see if we had glass ones or a cataract forming—vanished. Yes. He has turned astronomer when we meet, and wants a martingale quite as much as that brute of his with the ewe-neck that we called a stargazer. Then there's Steel, because we said his horse bored, has taken to terrestrial studies or counting his toes; whilst Oily Gammon, who was always pointing out and dilating in the plaintive notes of Philomela on the points of Shapeless, thinking that he was persuading us that she was far superior to the prize-winner Perfection, has stopped his piping, and with ruffled feathers shifts and sides about, or turns tail as if he had been shot at, or borrowed two-and-six. "Love me love my dog!" never, if he be a savage deformity or your horse a shapeless brute. But for the love we bear you, here we are at our post with the indelible pencil. The hour is ten—and the scene laid in Bingley Hall—the centre being fitted up as a circus, with Lord Combermere and Mr. Cookson in the open as judges; when in there comes dancing a mealy cheanout, with light wavy mane and tail, which add to his foreign appearance. It is Umpire, the American, by Le Comte out of Alice Carneal, by Imp Sarpedon, and a fair performer on the turf in his time, having started for forty races, and won thirteen. But now, he figures for the first time in a new character, being sent by his noble owner, the Earl of Coventry, as a candidate for prizes given for thorough-bred stallions calculated to get weight-carrying hunters. And if "like gets like," or anything like it, a pretty lot of weight-carriers they would be. He stands fifteen-three, and is a light horse all over, with a neat head and neck, capital shoulders, good quarters and thighs; but he is flat-sided, and the most waspy, herring-gutted animal we have seen for some time, and the least likely-looking, as far as form goes, to get hunters. Besides this, his forelegs struck us as being twisted, small

at knee, and light of bone; though it is only fair to say, they have stood him well during his racing career. His groom told us he had some very good-looking stock; but surely his noble owner never dreamt of taking a prize with him, and we think must have merely sent him to show those who go for form "an exception to the rule." The next on the list is old Motley, by Touchstone, dam by Lanercost, both stayers in their day, looking as sound and as well as ever. He took the Royal Hundred at Plymouth, and now adds another first prize to his long score of victories. He has got some very handsome stock, and this year there are eighty young Motleys, fifty of them being colts. After Motley comes the neat-topped, handsome Ivanhoff by Muscovite, out of Blackbird by Irish Birdcatcher, and as good a looking horse as one may see in a day's march, cutting him off, as we have often said before, at his knees. He has a sweet temper, allowing, his owner told us, Miss Griffiths, a child of eight years, to take him out for a ride by herself. He and Motley serve half-breeds at five guineas, whilst Umpire goes for eight. The other competitor was a nag by Newminster, out of Marchioness D'Eu by Magpie, a big, deep-topped horse, with something hunting-like about him, but anything but a taking one on the whole, or a free mover. It was a small class, but just at this season the lights of the harem require great attention, which keeps many of the lamplighters at home. Though only four to seven last year, we consider the thorough-bred stallion class an improvement, for among the seven last year there were some whose owners would have done their country more service by handing them over to the slaughterman, a character we hope soon to see appointed by the Government, instead of sending them stalking about the country in search of mares to propagate their wretched misshapen frames and rotten constitutions. Now for the weight-carrying hunters; send them in. That's Mountain Dew, the Islington prize-horse, walking clean away from the second to him there, a horse called Tyreconnel, and though he has one of the Chifneys of the show-yard up, he cannot keep his toe out of the tan with those shoulders. Then this rather smart servant's horse at first sight, but who will bear looking into, is the stout-made, good limbed, ever going Freeney; a nice one, barring the shoulders, which surely have encroached too much on that shortest of necks. The fair topped bay, a size bigger than any of the others, and who has not improved since we last saw him, is Hobby Noble, from the same stable, and second prize horse in this class last year, beating Little John, the Islington prize weight-carrier—that dummy of a horse, Master of Arts, being put over both their heads, a gay

deceiver, who was not found out, although we charmed never so wisely, till he had stripped the country of prizes to which, for the purpose, he was as much entitled to as the "Trojan horse" would have been. We forgot to say before starting for Troy that Freney was the second hunter here last year, without conditions as to weight. This snaffle-bridle horse, flourishing his feet about in a peculiar manner, handsomer and more symmetrical than any of them down to the knees, which from thence do not improve on inspection is a horse that pleased us much at Islington, Sparkenhoe by name, and he comes in here also for empty honours. Then there are the well-made, short-legged Pilot from Kenilworth, and Tupaley, a neat stylish grey of Mr. Corbett's, of Evesham. Captain Heath's two, The Chicken and Brewer, want fashion and breed—in fact, are the sort of horses, looking at them as hunters, to make one imagine we have gone back at least a century, and expect every moment to see Squire Western and Tony Lumpkin pop in the ring and claim them. There was a brown with something of a charger look, not in the catalogue. Of the four others, we hope their owner's heads will not ache until they get a prize. In the hunters without condition as to weight The General was quite the "primur genitur boy" of the party in breed, carriage, and form. He has greatly thickened, and let down to his leg since last year: his arms are much bigger, and as he is now rising six we about see him in perfection. He looked better than at Islington in himself; but what gave him a grander look here than he really has, grand horse as he is, was the company he was in, for he had nothing like Lady Derwent by his side. "Comparisons are odious," but nevertheless capital things to judge by. Balance-in-hand, the second to The General, is compact, well-made, with a nicely drooped quarter, and a good mover. He belongs to Mr. Westley Richards, who goes more for the useful than the ornamental, with an eye to a capital stamp of horse; Pilot, another of his, a neat light horse, being commended. The third, Thelka is a useful hunting mare, with good shoulders and quarters. The others we thought good-looking were the hunting-like Lancee from Melton Mowbray, but who bears the irons on some curby hocks; The Dean, from Mr. Lynes' Northampton, and a brother of Rural Dean, sold to the Prince of Wales, is very neat; while the Hon. R. C. Hill's Beak is a cobby under-bred looking animal, whose merit was not in his looks. Mr. King's Carragh is a blood-like looking hunter coming from Leamington, and looked like going; and Mr. J. Gilman's, Birmingham—was worthy of being named. In the four-year-old colts and fillies Mr. Westley Richards was first and third with Tipperary and Shambally, the former being a long low horse, with good a quarters and big limbs, but a heavy head, which gave him a want of breed; he needed a dash more blood like Shambally, who though not so powerful or good stand-still horse, was more to our eye. Brigadier was looking better than at Islington, and having a deep frame, time will tell on it, a very safe and quite oracular opinion for any one to give. A half-sister of Rural Dean, the Prince's horse, was very neat; Mr. A. Harrison's Paddy Carey well made; Mr. W. Goodliff Stow's Father Mewrad good looking, with plenty of blood; and Mr. Meyrick, of Bush, Pembroke, sent a nice sort of cheanut, whose Parson as a gig-horse we shall never forget.

Roulette, by Oscar, the first of the two-year-olds last year, repeated his victory in an indifferent class of three-year-olds. He shows breed and character, but is nothing of a mover, and the man who led him either had very little notion of giving a show or no intention. He was at Thrak Yorkshire Show last year, in better society, and passed unnoticed. But the junior classes are never very

strong in Bingley Hall. Tippler, by Claret, though a trifle flat-sided, has plenty of depth, and is a fair-topped horse, with blood; but is wrong in his forelegs, and his hocks look none of the best. He appears to have been roughly handled, and is as poor as a rook. Thunder-an-Turf, an Irishman, as his name indicates, does not look like rivaling forked lightning in pace. He was purchased at Ballinasloe fair, and is remarkable for his old-fashioned look; while he belongs to the owner of the famous old hackney mare Crafty, and was attended by the companion of her victories, who has been in search of something like her, but has not yet met with the desired object. Mr. Lort's highly-commended cheanut was here last year; he has length with some blood, and a good head, but has not quite the shape of a hunter. Ethel by Idler out of Rural Dean's dam, from Preston Deanery, had something pleasing about her. In a poorer class of two-years-old Curaçoa has a hunting top, but not the best formed hocks, and he was shown in very poor condition; Britannia bearing a strong resemblance to her sister Mr. Booth's British Queen, a well known filly from Killerby Hall, is by Laughing Stock out of sister to British Yeoman, and at present rather high on the leg. The judges having disposed of the above, as the buck-jumper remarked when he parted with his rider, resigned office. They were about two hours and forty minutes selecting the winners, and throughout acted well their parts. They had none of the horses jumped. This carried us on till a quarter to one, when the routine of a show-yard was set aside for a few old rattle-traps to be run round the ring, or while hacks verging on the butcher were trotted, or some hopped over a hurdle.

To drag people away from their homes and business for such trifling is too bad, and several came miles to see the show, but like the young Jew who fell from the gallery into the pit, did not. Some did not arrive till one on Tuesday, and when they found what was going on went away never to return. Two days and a-half did we swelter in Bingley Hall; two days and a-half waiting to see 240 horses, which included a lot of tag-rag and bobtail, in the shape of ponies and hacks, out and judged in vain, for up to twelve on Thursday the agricultural and dray horses were not looked at. And we came away, as who would not? disgusted with the systematic spinning out and childish trifling. Is it to delude people in this manner that noblemen and gentlemen kindly consent to act as judges, lend their names to give a respectability to the thing, and send horses and hounds? Is it in this way that horse shows have gained the popularity and ascendancy they have throughout the country? And is this the way to keep them so? No. Go to Yorkshire, Mr. Manager, go! In the carriage horses, a neat pair of browns, who were second last year, now took first honours, the second being a well-matched, rather cobby, pair of browns, while the commended were a pair of roans, and, as is often the case in pairs, one much neater than the other. There was nothing very attractive, and we think, in a circle of the dimensions of Bingley, the carriages might be left out, and the horses stripped, as fine feathers make fine birds. There were some nice hacks in the class exceeding fifteen-two; the fight for the prize lying between Thorngumbald's Pride, a very useful cobby mare, with limbs well placed, and quick strong action, just smacking of a little tutoring, and Ladylike, a title she is quite entitled by her perfect manners, a very good-looking hack, an inch over fifteen, and who went with such ease and grace, bending the knee and getting it well away without an effort, that it was quite the poetry of motion. The judges hung a long time here, and appeared anything but unanimous, having the saddles removed and the pair run up and down, dealer fashion. Then Mr. Welby rode them

round, but we fancy did not gain much information during the short time he was up, as either the mouth had not become accustomed to the hand, or the hand to the mouth. However, it ended, to the surprise of many, by the prize going to *The Pride*—we leave out the other name, being such a fearful mouthful—a decision that, had we been judging, we would have stood out against till Christmas, provided we had had a good breakfast, and were just a trifle deeper in our back-ribs. The others we fancied in this class out of a dozen were Mr. Gilman's (Birmingham) *Lelia*, and Mr. Price's (Churchstoke, Salop) *Honesty*. Old *Crafty*, a famous hackney mare, with her constant companion up, who is known by her name quite as well, if not better, than he is by his own—*Mulcaster*—looked as well as ever, and carried off the prize in the weight-carrying roadsters, to the surprise of no one, we should think. The second to her was a clever useful hack; *Cheshire Phenomena*, a third-prize one at Islington, and the neat *Tommy* coming in for commendations. *Bantam*, a pony with a nice head and large prominent eye, showing great breed and character, though as fat as butter, and with a hollow back, and was still very worthy of his honours; *Piccadilly*, a smart little pony, and a prize-taker at all points of the compass, being a good second; but the commended one, *Zara*, a nice pony, has not the best shoulders for a saddle. Pretty *Se-ensan* is a high-stepping cobby lass with the prison crop, and *Tommy*, who for the moment we cannot bring before us. In the ladies' hacks a *brown* mare of Mr. Holmes's, described as a chesnut in the catalogue, without a name, is a very nice mare for a lady, with form and fashion, but her hind leg action called forth many remarks, going as she did very screwy. Between her and *Beauty*, a deep good-topped bay, and not badly named—she is by an Arabian of the King of Sweden—and for whom we should have again held out, the judges hung a long time before coming to a verdict. Mr. Turner's (Birmingham) *Lady Jane*, Mr. Casson's *Gipsy*, and Mr. C. Richards's blood hack were the next we fancied.

In the ladies' horses under fifteen, a mare entered in the hacks and roadsters exceeding 15 hands, called *Bonny Lass*, and who we were told was disqualified as to height, was allowed very improperly to compete. She is a very handsome mare, with loaded shoulder points, and had the first prize awarded to her, when some one objected, and the prize went to the second and commended, but not before Mr. C. Richards was called in as referee, who went for *Duchess*, a nice-shouldered mare, with a hollow back, and who moved better than *Polly*, her opponent, a finer-made mare, barring her shoulders, which were nothing like so good. Mr. Thornley's *Bayard* exhibited a very neat one for a lady. The harness horses were anything but a grand lot, barring the winner, *Kate*, who is a finished mare with stylish action, and the second a neatish bay. In the ponies 13½ hands *The Duchess* was waited on by John Brown and several fine goers, among them *Leybourne*, a Birmingham trotter, and second-prize taker last year. Still we believe to be seen alive, as stated by the local papers, as "the winner of the exciting trotting match at Islington." Exciting! we should rather think it was, at the "turn of the tubs," where you expected some one to come over neck and crop every time, in a space more adapted for spinning a tectotum than to let a trotter out at top speed. Trotting match—bosh! *Multum-in-parvo*, a pony under 13½, and a really nice one, of whom we gave a description in our Islington Show, where he was first, had several good-looking ones to keep him company; while the lengthy *Bobby*, a prize-taker here, and this time of a silver medal, had only two others against him, as the best entire pony. *Alice*, the piebald pony that the Princess of Wales admired so much at Islington, and bred by Mr. Drake, the late Master of the Bicester Hounds, was picked out as the best child's pony.

And so she is, if any one has got a large family and wants them dispersed; as such she would prove invaluable, for there is no telling where she would send them flying or take them to. She is an inch under 12 hands, very well made, and looks all over like going; but is the most unruly, self-willed, boring, plunging little vixen we have seen in a small compass for some time; reminding us of some of the racing ponies of our youth, who would unsettle a monkey strapped on, if not let out for a spin. Surely Messrs. Welby and Topham must be as fond of little ones as the swell in difficulties, who told the bootmaker when he informed him that "he had taken the liberty of bringing his 'little bill,'" to "take him out of his sight, for he hated the sight of children!" There were four pairs of good-looking dray horses, those that struck us as the best being Mr. C. Brierly's *Prince* and *Boxer*, the former being a great framed horse, with a capital forehead on a short leg, and the latter with a remarkably good head, and movement as light as a pony. They were second at Manchester last year to an extraordinary pair, but have wonderfully improved since. The two of Mr. Evans, of Birmingham, were also greys; *Charley*, the old horse, being a rare shaped one, with great depth of middle, short-legged, and active looking, but begins to show age and signs of work; *Dick*, his companion, a five-year-old, is also very good, but has not the character of the old one. The Midland Railway was represented by a pair of very handsome blacks, of great weight, but not a match; and Mr. Brown, of Handsworth, with two useful ones, a grey and bay. There were four agricultural stallions: A 1, bred in Bucks, a plain headed animal, coming for the blue ribbon, as he did last year, and afterwards at the Gloucestershire and Warwickshire meetings. *Tom Sayers*, who, from the glance we could get of him in his box, was rather common looking; and *Young Sampson*, of Burnley, Lancashire, the other competitor, and a winner of a necklace of local prizes was sent empty away. The agricultural pairs had a prize for each. Among them was a mare called *Dumpling*, a lengthy, low, well made mare, who has taken a second prize two years in succession, and now comes in for a first.

The hounds were judged on some planks in the circle; and the eccentric attitudes and knowing way the three old huntmen, famous in story, went to work seemed to please the ladies quite as much as an exhibition of *Punch* and *Judy*. First *Jack Walker* would put his head on one side in the most comical position, and have a half-doubting look at a hound; but as that wouldn't do, he turned it to the other for a squint. But when *Will Long* began to tape them round the middle, arms, ankles, and divers other parts, the approving smile Mr. Walker gave him, as much as to say, "William, you are a doing of it," and when 'Arry Ayris put on his specs for a stare, is beyond all description. The ladies were in ecstasies, some putting their pocket-handkerchiefs to their lips to prevent them from shrieking outright.

#### PRIZE LIST.

JUDGES.—Viscount Combermere.

Mr. J. Cookson, Neasham Hall, Darlington.

#### STALLIONS.

Thorough-bred stallions for getting weight-carrying hunters.—First prize of £30 to Mr. J. Casson, *Burgh-by-Sands*, Carlisle (Motley); second of £10 to Mr. E. Griffiths, *Marle Hill*, Cheltenham (Ivanhoff).

#### HUNTERS.

Five years old and upwards, equal to 15 stone.—First prize of £35 to Captain E. N. Heygate, *Buckland*, Loomister (Mountain Dew); second of £10 to Mr. Westley Richards, *Birmingham* (Kreeney); third of £5 to Captain Fyler, *Wareham*, Dorset (Tyronnel). Highly commended: Mr. Henry Allsopp, *Hindlip Hall*, Worcester.

Five years old and upwards, without condition as to weight.—First prize of £25 to Mr. G. Holmes, Beverley (The General); second of £10 to Mr. W. Richards, Birmingham (Balance-in-Hand); third of £5 to Mr. George Van Wart, Edgbaston, Birmingham (Honeydew). Commended: Mr. W. Richards (Pilot); the Hon. R. C. Hill, Hawkestone, Shrewsbury (Becka).

Four-year-old colts or fillies.—First prize of £20 to Mr. Westley Richards, Birmingham (Tipperary); second of £10 to Mr. J. B. Booth, Killerby Hall, Catterick (Brigadier); third of £5, to Mr. W. Richards (Shanbally). Highly commended: Mr. W. Goodliff, Stow, Weedon (Father Mewrad). Commended: Mr. T. Meyrick, Bush House, Pembroke (chestnut filly).

Three-year-old colts or fillies.—First prize of £20 to Mr. G. Wise, Woodcote, Warwick (Boulette); second of £10 to Mr. Westley Richards, Birmingham (Tippler); third of £5 to Mr. H. J. Percy, Howsenrigg, Aspatria, Cumberland (Tander-an-Turf). Highly commended: Mr. W. Lort, The Cotteridge, King's Norton (chestnut). Commended: Mr. G. McKnight, Oakengates Salop (Maggie).

Two-year-old colts or fillies for hunting purposes.—First prize of £15 to Captain E. N. Heygate, Backland, Leominster (Curagoa); second of £10 to Mr. J. W. Gardom, Butterton Park, Newcastle (Britannia); third of £5 to Mr. Robert Emerson, Darlington (Lillie). Highly commended: Mr. James Hughes, Broome, near Alcester (chestnut filly); Commended: Mr. Wm. Boddington, Liddington, Stratford-upon-Avon (bay colt).

#### CARRIAGE HORSES.

JUDGES.—Mr. J. C. Welby, London.

Mr. J. Topham, Welford, Rugby.

Pairs.—First prize of £20 to Mr. C. J. Shaw, Harborne Road, Birmingham (Shakespeare and Greenfield); second of £10 to Mr. Smith, Birmingham. Commended: Mr. James Oldham, King's Heath (Strawberry); Mr. J. Oldham, Leamington (Jessie).

#### HACKS, ROADSTERS, AND COBS.

Hacks and roadsters exceeding 15 hands high.—First prize of £15 to Mr. J. H. Dennis, Burstock, Holderness (Thorn-gumbald's Pride); second £5 to Mr. J. Sankey, Birmingham (Ladylike).

Weight-carrying hacks, from 14 to 15 hands high.—First prize of £15 to Mr. H. Percy, Aspatria, Cumberland (Crafty); second of £5 to Mr. T. Smith, Wootton Downs, Woodstock (Jenny Jones). Commended: Captain St. Clair Ford, Cheltenham (Cheshire Phenomenon); Mr. J. Gilman, Birmingham (Tommy).

Cobs under 14 hands high.—First prize of £15 to Mr. R. H. Watson, Wigton, Cumberland (Bantam); second of £5 to Captain F. Barlow, Castle Donington, Derby (Piccadilly). Commended: Mr. F. Pearoe, Steeple Acton, Oxon (Zara); C. Groucock, Stanfield Hall, Wymondham (Pretty Seamusan).

#### LADIES' HORSES.

15 hands high and upwards.—First prize of £15 to Mr. G. Holmes, Beverley (brown mare); second of £5 to Mr. J. S. Keep, Park Road, Edgbaston (Beauty).

Under 15 hands high.—First prize of £15 to Mrs. Webb, Edgbaston (Duchess); second of £5 to Mr. J. W. Shaw, Moseley (Polly). Commended: Mr. Thornley, Yardley, Birmingham (Bayard).

#### HARNESS HORSES AND PONIES.

Exceeding 15 hands high.—First prize of £15 to Mr. J. S. Keep, Edgbaston, Birmingham (Kate); second of £5 to Mr. C. L. Boyce, Balsall Heath, Birmingham. Highly commended: Mr. A. Cooper, King's Heath (chestnut).

From 13½ to 15 hands high.—First prize of £15 to Mr. T. Worthington, Litchurch Villa, Derby (Duchess); second of £5 to Mr. H. Davis, Great Hampton Street, Birmingham (John Brown). Commended: Mr. J. Bate, King's Heath.

Ponies in harness under 13½ hands high.—First prize of £10 to Mr. J. Gilman, jun., Lancaster Street, Birmingham (Maltum in Parvo); second of £5 to Mrs. H. Chavasse, Soho Park, Handsworth (Kitty).

#### PONIES.

Under 13 hands high.—First prize of £10 to Mr. C. John-

son, Park Road, Birmingham (Fan); second of £5 to Mr. D. Hedges, Bull Ring (Oxford Joe). Commended: Mr. F. Haines, Bromford Villa, Ealing (Princess). Commended: Messrs. Johnson, North Lindsey, Warwick (Tommy).

Under 12 hands high, to carry children.—First prize of £10 to Mr. C. Thomas, Banbury (Alice); second of £5 to Mr. J. Lane, Bristol Road, Birmingham (Black Prince).

#### STALLIONS.

Not under 14 hands high, for getting hacks or roadsters.—First prize of £15 to Captain Barlow, Castle Donington (Lucifer); second of £5 to Mr. J. Edwards, Sudbury Paddocks, Middlesex (Shepherd F. Knapp).

Ponies.—Silver medal to the Most Noble the Marchioness of Hastings (Bobby).

#### DRAY HORSES.

Pair of horses (geldings or mares) four years old and upwards.—First prize of £15 to Mr. C. W. Brierly, Middleton, Manchester (Boxer and Prince); second of £10 to The Midland Railway Company (Blacks).

#### AGRICULTURAL HORSES.

JUDGES.—Mr. J. E. Bennett, Bosworth Grange, Rugby.

Mr. C. Randall, Evesham.

Mr. Shepherd, Coleshill.

Stallions.—First prize of £30 to Mr. W. Wynn, Alcester Redditch (A 1); second of £10 to Mr. P. Leather, Warrington (Tom Sayers).

Pairs of geldings or mares.—First of £15 to Mr. S. Davis, Woolashill, Pershore (Dumpling and Darby); second of £10 to Mr. C. Brierley, Middleton, Manchester.

#### FOXHOUNDS.

JUDGES.—H. Ayris, W. Long, and J. Walker.

For two couple of dogs.—First prize of £15, and £3 to the huntsman, to Mr. Oswald Milne (The North Warwickshire), Saffron, Guider, Hunter, and Prodgal; the second of £10, and £2 to the huntsman, to The Earl of Yarborough (The Brocklesby), Bluecap, Villager, Gaylad, and Castor; third of £5, and £1 to the huntsman, to Lord Fitzhardinge (The Berkeley), Pomfret, Dissolute, Rubens, and Premier.

Two couples of bitches.—First prize of £15, and £3 to the huntsman, to Lord Yarborough (The Brocklesby), Graceful, Reckless, Gaiety, and Niobe; the second of £10 to Mr. Oswald Milne (North Warwickshire), Boxy, Nancy, Rally, and Damsel; third, Lord Fitzhardinge (The Berkeley), Truelove, Languish, Petulant, and Paleface.

Couples of unentered puppies, one of each sex.—First prize of £10, and £3 to the huntsman, to Mr. C. Colmore (The Cotswold), Render and Ruin; the second of £5, and £1 to the huntsman, to Lord Yarborough (The Brocklesby), Ben-tinck and Handsome.

**A TROPICAL FOREST.**—The general aspect of one tropical forest is much the same as another, varied occasionally by a vegetation discovered only on nearer inspection as more peculiarly its own. Nothing can exceed their beauty. A rank luxuriance, a wild unrebuked race of vegetable giants, the tangled festoons of creepers starred with the most brilliant flowers, hanging down like stringed jewels; then the great big orchids. How one smiles afterwards at the pigmy specimens of artificial hothouse culture! One very frequent is like a huge bird's nest—the name in fact of the species—embedded in the forks of the largest trees; yards and yards of "lianes" are frequently suspended on the gnarled distorted limbs above and about it; such is a faint idea of the picture presented right and left as one breaks one's way through the heart of a primeval forest in the tropics. If you look down there are green depths as it would seem bottomless; if you look up there is roof upon roof of an exquisitely variegated verdure, the tall fern-tree piercing through the under and densely-tangled vegetation with its umbrella-shaped head waving like a coronet of feathers. At times you see the ghastly bared shape of some tempest-stricken child of the woods stretching across as if to hide its nakedness among the surrounding millions of leafy things. The hope of giving any adequate idea of the witchery of a scene like this is vain.—*Boyle's Mauritius Sketches.*

## HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

The stated half-yearly general meeting was held in Edinburgh on Wednesday, June 24; the Duke of Buccleuch and Queensberry, president of the Society, in the chair.

Mr. F. N. MENZIES, the secretary, read the names of the new members, 104 in number, who were balloted for and duly admitted.

The CHAIRMAN said he had now to report to the meeting that an answer had been received to the address from this Society to the Queen on the occasion of the atrocious attempt on the life of the Duke of Edinburgh. The Duke of Montrose was still in charge of the address to the Duke of Edinburgh until he had an opportunity of presenting it to His Royal Highness on his arrival in this country.

Mr. WALKER, of Bowland, said it would be in the recollection of the members of the Society that at the last general meeting of the Society it was agreed to give a sum of £150 for ten years towards the endowment of the Chair of Agriculture in the University of Edinburgh, or rather to assist in providing a salary for the Professor of that Chair. The grant was given on condition that Government should contribute an equal or greater sum for that purpose. He had now to report that the directors made the necessary application to the Government, and he had the satisfaction to state that a reply had been received to the effect that the Lords Commissioners of the Treasury were pleased to place on the estimates of 1868 the sum of £150 for that purpose. He had also to state that the University had fulfilled their pledge in order to make the Chair more useful than it had hitherto been, by instituting degrees in agriculture, the examination in which is to be conducted by the University examiners in conjunction with an examiner appointed by this Society.

The report was adopted.

The Secretary reported that the arrangements for the show at Aberdeen, on the 28th, 29th, and 30th July, were in a satisfactory state of advancement, and that there was every promise of a most successful meeting. Nearly 1,200 head of stock have been entered for competition, besides upwards of 460 head of poultry, and a very large number of implements, as well as general collections of seeds and roots, and conifers, and other forest trees.

Professor BALFOUR reported that at a meeting of the Council on Education, held on the 18th March, the Society's Diploma in Agriculture had been conferred on Mr. Thomas John Elliot, Wilton, Salisbury; and the certificate on Mr. James Taylor, Allan Vale, Pitmuir, Aberdeenshire. He also stated that the prizes of £6 and £4, annually allowed by the Society to the students in the Agricultural class in the Edinburgh University who pass the best and second best examination, had this year been awarded to—1st, G. R. Glendinning, Mid-Lothian; 2nd, G. G. Bursby, Northumberland. The Professor concluded by reporting that at the recent examinations by the Royal Agricultural Society of England the principal prizes were gained by students in the class of Agriculture in the Edinburgh University, and that every one of the Edinburgh agricultural candidates took a first prize. There were twelve candidates, of whom six obtained prizes; and out of the six prizemen four were Edinburgh men, three of them having already obtained the diplomas of the Highland Society.

The report was approved of.

Mr. CAMPBELL SWINTON, of Kimmerghams, gave in the following report of examinations of the Veterinary College: "The examination of the students for the Society's Veterinary Diploma took place on the 15th and 16th April, and were conducted by four separate boards. Thirty-two students presented themselves, and, after a careful and searching examination, the Society's diploma or certificate was conferred on twenty-nine. Six silver medals were awarded by the Society for the best examination, as follows: 1. Anatomy—Andrew Spreull, Milngavie; 2. Chemistry—Frederick W. Going, Mullenahone; 3. Horse Pathology—Jonathan Bunnell, Liverpool; 4. Materia Medica—Joseph L. Faulkner, Wetherby; 5. Physiology—Andrew Spreull, Milngavie; 6. Best General Examination—George Lawson, Aberdeenshire."

The report was approved of.

Mr. CAMPBELL SWINTON said he had to report upon another matter connected with veterinary science, in regard to which, he was sorry to say, that they had hitherto met with ill-success—he referred to the effort which had been made to obtain a charter for a General Royal Veterinary College in Scotland. The members were aware that, in conjunction with the Lord Provost and magistrates of Edinburgh, acting as trustees of the Dick College, and also acting in conjunction with other public bodies in that city and elsewhere, and with a large number of the veterinary surgeons in Scotland, they had made an application to Government asking them to institute a Royal Veterinary College, not connected specially with Edinburgh, but to hold the same position which the Veterinary College in England did, and to give diplomas, degrees, and certificates to students attending any veterinary establishment where suitable education was given. He was sorry to say that hitherto their efforts had not been attended with success. The last letter which had been received from the Board of Trade on the subject, which was addressed to their London agent, was dated May 15, and was as follows:

Council Office, May 15, 1868.

SIR,—I am directed by the Lords of the Council to inform you that their lordships have had under their consideration the petition lodged by you at this office on behalf of the Highland and Agricultural Society of Scotland, and of the trustees of the late Professor Dick, praying for the grant of a charter of incorporation to the Royal Veterinary College of Scotland, and I am to state that their lordships, after mature deliberation, find themselves unable to recommend her Majesty to grant the charter prayed for.—I am, &c.,

(Signed) ARTHUR HELPS.

John Graham, Esq., 3, Westminster-street.

That answer evidently proceeded on a misapprehension, because it refused a prayer for a charter of incorporation to the Royal Veterinary College in Scotland, while there was no such body in Scotland. They seemed to be confounding the College, the establishment of which they asked for, with the school of veterinary medicine which existed in Edinburgh. He hoped, therefore, they might still hold out some expectation that when that mistake was properly explained their just demands in that matter for Scotland would receive greater consideration from the authorities in England than they had hitherto met with. Probably the society would be willing to remit the matter to the directors, knowing as they did what zealous friends they had in their noble president and in members of both Houses of Parliament, who were anxious still to take that matter up and press it on the attention of the Government.

The Duke of BUCCLEUCH said that the letter which had just been read by Mr. Swinton showed that there must be some misapprehension of the object of the Society in asking for this charter. No reason had been assigned for the refusal, and he thought they had therefore a very good right to press the matter still further, and ascertain really what was the objection to granting a charter to a veterinary college in Scotland. He knew, from what he heard last year, that there was an excessive amount of jealousy in certain quarters against the establishment of a veterinary college in Scotland. They had an idea that a veterinary college in England was the only one that ought to be supported, and that every person must go to London to get his diploma. He would like to know how they would have been if there had been no Royal College of Surgeons or Physicians in Scotland. He was not one who felt at all inclined to yield to pressure of that sort; and when he went to London he would make it his duty to endeavour to ascertain the grounds upon which this refusal was based, and, if possible, to procure the publication of any documents upon the subject, by moving for all the correspondence which had taken place between the Board of Trade and that Society, and all other public bodies, upon the subject. He thought they should still press it strongly upon the attention of the Board of Trade.

Mr. IRVINE, of Drum, laid on the table No. III. of the fourth series of the *Transactions*, and then read the list of premiums awarded for reports as follows:—

The gold medal, or £10, to James Purves, Lochend, Thurso, for a report of the improvement of seventy-five acres of meadow pasture, by relieving it from injurious flooding, executed in 1864 and 1865, on the Leens of Torran, part of the Crown lands and grazings of Dorrery, in the county of Caithness.

The medium gold medal, or £5, to John Honeyman, Crosby, Isle of Man, for a report on the Isle of Man—its agriculture, climate, &c.

The silver medal, to H. Newby Fraser, Wyseby Hill, Ecclefechan, for a report on the agriculture of Dumfriesshire.

The silver medal, to William Gilchrist, forester, Midmar Castle, Echt, Aberdeenshire, for a report on the formation and management of young plantations.

The silver medal, to Robert Hutchison, of Carlowrie, Kirkliston, for a report on trees not liable to be destroyed by rabbits.

The silver medal, to John Morrison, Coney-park Nursery, Stirling, for a report on the Cornican fir.

Dr. ANDERSON reported that the laboratory work had been very arduous during the last half-year. The number of analyses had very materially exceeded that of any previous half-year, and the results which had been obtained from them were in many respects extremely important to the agriculturist. This year the number of inferior manures in the market was very considerable, and these were very often sold under names to which they were not entitled. In some instances, manure said to consist of dissolved bones was almost entirely formed of coprolites and other mineral matters, and in many cases these manures were sold at prices nearly double their intrinsic value. He had also had occasion to examine a very large number of oilcakes, and here adulteration was carried on to an extraordinary extent. Although it was a mere guess on his part, he would say that there were thousands of tons of oilcake sold in Scotland during the past six months, mixed with bran, cottonseed, and other substances. In one case, the adulteration went so far that he might almost say that the justification for the name of linseedcake lay only in this, that a little of that material had been put among the other substances. These adulterations were done so artistically that they deceived the eye, and the article appeared to be the genuine oilcake; so that, unless care was taken, the adulterations might escape notice. The whole of the field experiments had been arranged for this season. Certain of the experiments of last year were to be repeated, while a series of other experiments on a large scale had been commenced. The manures were to be of the kinds most commonly used—such as farmyard manure, Peruvian guano, and so forth. He thought that the result of these experiments would be of great importance to the farmer.

Mr. HARVEY, Whittinghame Mains, said he still thought, as he thought a few years ago, that there should be a chemical department in Edinburgh. Glasgow was renowned for commerce, but not for agriculture. The eastern part of Scotland had by far a greater interest in agriculture than the west; and he thought that the present arrangement was very inconvenient for the farmers in this district. With regard to the adulterations mentioned by Dr. Anderson, he wished to know whether something could not be done to check such a system by advertising the firms who sold adulterated material. He knew there was a difficulty in regard to pouncing upon firms selling adulterated manure, but it was a system by which the farmers suffered very greatly, and it ought to be inquired into. He thought that the chemical department of the Society was not in that satisfactory position that the farmers of Scotland were entitled to expect. He was of opinion that they ought to have a model farm connected with the Society, as there was nothing like seeing practical work. He had no great faith in farmers carrying out these experiments, as they were often transferred to a substitute. He would mention a case in point. Two most respectable farmers in the county of Roxburgh on a recent occasion undertook the experiments, and what was the result? A drain had burst in both experiments, and no practical result was arrived at. A model farm, in his opinion, came nearer the mark, as in that case a person would be appointed of undoubted integrity to see that every pound and ounce of the produce raised would be weighed thoroughly

out, and a greater power and a greater force would be connected with these experiments. He was aware that there was some difficulty with an experimental farm—it would cost money; at the same time, to gain the confidence of the farmers of Scotland, perhaps it would be the best plan that could be devised.

Dr. ANDERSON said that it was true, as Mr. Harvey had stated, that the greater part of the analyses came from the eastern districts of Scotland. He very much feared that in some parts of the West, agriculture was not so much advanced as to induce the farmers to take advantage of what the railways could do. The best mode of putting a stop to adulteration was a question of very great difficulty. He feared that it would be rather a dangerous proceeding to venture upon, advertising the names of adulterating dealers; at least, if such a thing were done, he certainly hoped the Society would take any responsibility in the matter off his shoulders. As far as model farms were concerned, there was no doubt that a great deal of important information could be got from such farms if they could be got up. The difficulty in that matter was chiefly a pecuniary one. A model farm could not be carried on at a profit; it had been invariably found that such a farm must be carried on at a loss; and the whole question would be how to obtain the pecuniary means to carry on such a farm, which would certainly not be small, when it was taken into account that the researches of Mr. Lawes cost him £2,000 a year. These were experiments, no doubt, on an extensive scale; but that gave some idea of the cost of these experiments, and Mr. Lawes certainly carried on his experiments in a very economical manner.

Mr. MILNE-HOME said that, in regard to the suggestion of a model farm, that matter was brought before the directors at one time by the late Mr. Finnie, of Swanston, and a part of Linlithgowshire was suggested as a place where a model farm could be obtained. At that time Professor Low was in the Chair of Agriculture, and gave his assistance to the directors in considering the matter; and the result of the deliberations of the directors was that a very large sum would be required to pay the rent and expenses of a model farm, because it would be conducted upon principles totally different from those upon which ordinary farms were carried on; because, while farmers only grew those crops which had been ascertained to yield a profit, the object of a model farm would be to try unknown experiments, which in nine cases out of ten would result in failure and a large expenditure. Unless, therefore, the Society was prepared to set apart a considerable sum, the idea of starting a model farm was Utopian; but he did not see why the well-managed farms in East-Lothian might not afford the same facilities for field experiments which a model farm could afford. If some of those gentlemen so intelligent in agriculture were to allow a small portion of their land to be used for well-conducted experiments, the same results might be secured as by a model farm at far less expense. Considering the great importance of agriculture in the east of Scotland, he thought there ought to be some establishment connected with chemistry in Edinburgh as well as Glasgow, and perhaps Professor Anderson and the directors might be able to make some arrangements to meet the views of Mr. Harvey in that matter. Considering the importance of East-Lothian, he thought there ought to be some chemical establishment nearer them than in Glasgow.

Dr. ANDERSON said that Mr. Milne-Home's suggestion in regard to certain farmers setting aside part of their land and making experiments was being carried on. The field experiments were being carried on by some of the most distinguished agriculturists, and they were carried on in a very admirable footing. The gentleman have been selected as those experienced in such matters. With regard to Mr. Harvey's remarks as to the chemical department, he (Dr. Anderson) made a proposal at the time he went to Glasgow that a certain part of the work of the Highland Society should be done in Edinburgh, but the directors thought it was entirely unnecessary, and that the work would be better consolidated in one place.

The CHAIRMAN said as to the proposal to have a model farm, his idea was that, for such a thing to be of real utility, they would require not one model farm, but half-a-dozen. He thought that the experiments were not so necessary on fine, rich, deep loam and soil, but they ought rather to be made on clay and cold lands, and where there was a bad climate. It

was on farms situated on such districts that, in his opinion, they required to make the experiments. It was not always the best land that was the best to make experiments upon. He saw the peculiar difficulties of having a model farm. After one was erected, there might be a proposal to establish others in different parts of the country, which would cause great expense to the Society. Most of the proprietors of Scotland had got farms of their own which they did not always find to be very profitable, and he would suggest that it would only be a little additional loss if they were to make a few such experiments as were desired.

Mr. HARVEY said his idea was that they should have a model farm in a central part of the country. He did not like the experiments of farmers themselves, as they were often very carelessly conducted. They had spent a great deal of money

on the chemical department, and he did not think it had been worth ten straws to them. With a model farm, they would have ocular demonstration of what might be accomplished. Mr. Harvey further stated that he never for a moment thought of proposing that a model farm should be established about Dunbar, or within three or four miles of Edinburgh, where abundance of manure could be supplied, but in a central district of Scotland—perhaps in some district between the eastern and western oceans, and land not naturally in a high condition, where all manure supplied shows itself more minutely; then there would be something like data to work upon. These were his opinions, and he was fortified in them by present and ex-directors of the Society.

A vote of thanks having been given to the Duke of Buccleuch for presiding, the meeting separated.

## THE CAMBRIDGESHIRE AND ISLE OF ELY AGRICULTURAL SOCIETY.

### MEETING AT NEWMARKET.

The Cambridgeshire is not a Society of much calibre, its operation apparently extending but occasionally beyond the confines of the county into Essex, Norfolk, and Suffolk. Neither does the aim look like a very high one, the prize-sheet being cut up into a number of petty premiums and a multiplicity of classes—animals of the same sort or age entered or winning in one not being eligible to compete in another, until every man gets something in turn. This is no doubt all pleasant enough; but it is not the way to make an impression, or to develop a show of much character. Let the money subscribed by the districts visited be thrown into the general classes, and the premiums proportionately increased, so that we shall hear no longer of such parish offerings as £4 for a best bull and £2 for a second. The Society would seem to possess the chief elements of success; but its conduct calls for careful revision and greater scope. The system of keeping the thing down, and of neighbours rewarding each other, is pretty certain to come to grief, as it has done in Essex; while so far as any example or lesson be concerned, we can learn but little by staying at home.

The Newmarket meeting was, nevertheless, a creditable one; although, as it strikes us, it might have been better had its forces been concentrated instead of scattered. There was something wearisome alike to judges and spectators in encountering an infinite succession and repetition that went often enough to make a distinction without a difference, and this was more especially the case in the horse section. The cattle, or more properly the Shorthorns, did not either for numbers or merits equal the display at Wisbeach last year, although amongst the more prominent prize-takers were Lady Pigot, Mr. Pawlett, Mr. Hugh Aylmer, and Mr. How, of Broughton. But her Ladyship's two bulls look to have had quite enough of it, and Charles le Beau, more particularly, although placed first in his class, was terribly faded and cut up by his travels; as he of course shows this the more from being at best but a delicate animal. Rosolio, and Mr. Aylmer's General Hopewell young bull were entered in different classes at Downham, the West Dereham being then third in the old class. He is not a bull of much appearance, and had Lady Pigot's been fresher he might have reversed the decision. Young stock, however, above all others, cannot stand such incessant excitement, and any chance the Branches herd might have had for Leicester would threaten to be destroyed. The judges noticed nothing further amongst the yearlings, but beyond Mr. Pawlett's second prize for his round, thick Baron Warlaby, they highly commended a Thorndale Grand Duke of Mr.

Aylmer's in the older class. The bull calves, where Lord Braybrooke was first with one not noticed at Chelmsford, and Mr. Frere of Roydon second, were both very moderate; and in a short class of cows Mr. How's Jolly Queen, the second at Downham, had it all her own way, Jennings the trainer being a bad second. There was nothing very particular, again, about Mr. Frere's or Mr. E. Durrant's first and second two-year-old heifers; but Mr. How's Lady Anne, the best yearling, or nearly two-year-old, is a very sweet lady-like creature, quite worthy of her £4 premium, and immeasurably superior to Mr. E. Frost's poor second; any comparison being further emphasised by Victoria Spes, about the worst animal John Ward ever led into a ring: being not only bad in herself, but badly done by. It was at first thought that her ladyship had lent her herdsman to some neighbour for a show; but his charge, alas! is Branches, born and bred. There was only one heifer-calf—Mr. Frost's Strawberry, which took the prize on the distinct understanding of there being nothing against her; while Mr. Durrant's capital cross of the Shorthorn and Angus had, as in Norfolk, all the best of the fat beasts, taking first for oxen or heifers pure-bred or otherwise, and again for steers or heifers by a Shorthorn bull out of a half-bred cow. There was a second prize in the former of these classes, which Mr. Frost won with a Shorthorn, and where Mr. How and Mr. Adeane were commended; but nothing could touch the Aberdeen cross amongst crosses. Over the polled cows of the country, where Mr. Peddar, of Kennett, was first, the judges must have had some difficulty in trying to award the three prizes, the one solitary distinction for Alderneys going to Mr. J. S. Tharp, of Chippenham.

The show of short-wooled sheep was very much an echo of that at Chelmsford, Lord Braybrooke having it all to himself with the Shorthorns, Mr. Giblin going for Oxforda, and Mr. Green, of Stradishall, leading the way with the blackfaces on their native heath. In the first class of short-wool rams, Mr. Giblin, of Bardfield, beat Lord Braybrooke for best with an Oxford, the judges considering the Audley End sheep as pretty generally too delicate; but in the pens of shearing short-wool ewes the positions of these two sorts were reversed, Lord Braybrooke's Chelmsford five being first, and Mr. Street's Oxforda second. For the pens of short-wool lambs, Mr. Samuel Jonas did deservedly well with four very good lots, which took first and second prizes for rams, and second and a commendation for the ewes, where Mr. Northern, of Moulton, was first, and Mr. Jary of Westley, commended for his Black-face and Down

cross. The judges took a deal more kindly to Lord Braybrooke's really good fat shearing wethers, which were placed first and second, with picked three from the Chelmsford fives; Mr. Street being highly commended for some very good Oxfords, and Mr. Dobito receiving a similar compliment as one of "the Suffolk" champions. With little or no competition, Mr. Battcock, of Hemmingford Abbots, was first and second in two classes of cross-breds, pens of ewes and pens of wether lambs, with the now-very-popular "nick" of a Cotswold ram put on to a Hampshire Down flock; but in the class of fat wethers Mr. Street beat these for first place with his Oxfords. For Mr. Henry Webb's cup for the best shearing South-down ram there were only three entries, and these three all by Lord Braybrooke; the best ram in Essex being also the best here, but the judges now reversing the places of the second and third. The other special prizes included a class of cross-bred ewe and ram lambs, where Mr. Battcock was still first, as well as second in the ram class, and Mr. Jary second in the ewes, with the produce of a Lincoln ram and Hampshire Down ewes. Mr. Green won nearly all the chief premiums for Suffolk black-faces, being first for old rams (where Mr. Dobito was second), and first, second, and commended for shearing rams. But there was altogether a very strong show of these sheep, with Mr. G. Jonas, Mr. Jary, Mr. G. King, Mr. Northern, and Mr. Frere's executors amongst the winners, and the judges speaking to a very visible improvement, which they attribute to a dash of Hampshire blood. The longwools were mostly Lincolns and Cotswolds, but there was little or often no competition; and Mr. Gunnell, of Milton, and Mr. Giblin took all the chief prizes for rams, ewes, and lambs, the only exception being in the two classes of shearing Leicester or Lincoln ewes, where Mr. T. O. Daintree was first for the old ewes and first and second for shearlings with some good sorty sheep, especially the shearlings bred from a Lincoln ram of Mr. C. Clarke's, of Ashby-de-la-Lund.

There were not a dozen pigs in the six classes, and Jennings, the trainer of Gladiateur, had all the best of it. His first white boar is of Lord Wenlock's breed, and his big black sow, a Cheshire pig from the stock of the late Captain White. These Cheshires are said to feed famously, and to be quite the admiration of the Newmarket jockey-boys; but we cannot say that we know much of the sort. The two prizes for small boars were duly awarded to the two entries, Lady Pigot first, and Mr. Jillings second; and Mr. King, of Ashley, took first for small sows in two classes with one really nice pen of young pigs.

The horse show was generally moderate, and, strangely enough, there were amongst the riding-horse classes some of the very worst animals in the whole catalogue. Nothing, indeed, could be well worse than the stallions calculated to get hunters, as even with Mr. Thurnall amongst them, the committee neglected to insert the thorough-bred clause, and so of course, as is now generally the case under such circumstances, the entry was a failure. As an example, the premiums should never have been awarded; but the judges were induced to do so, although we feel very certain that neither of them would ever think of trying to breed a hunter from their first prize. This was a halfbred trotting horse, by Fireaway, the property of Mr. Mitchell, that might have been in his place in the next lot of hackney stallions, where Mr. Baltista won with Clearaway, a Norfolk horse with showy action; Mr. Reed, of Downham Market, getting second with his well-known Trotaway. This was a creditable class, in which Mr. Joelyn showed a good-looking horse, pulled down by doubtful forelegs; but the hunting brood mares were indifferent, Mr. Linton taking the first prize with a mean-looking King of Oude mare, and the Rev. W. Smith second with an old mare by Jericho, of more character

than the other. The hunting classes were saved by a couple of entries from Mr. Gardner, of Moulton, his four-year-old being the best of two or three duplicate classes, and a winner amongst the younger horses as well as of a special prize to much the same effect. In some sort of commentary on the hunter-sire class this colt is quite thoroughbred, by Touchwood, out of Lord Burleigh's dam; and in some further commentary on the jumping business, it may be added that the four-year-old resolutely declined to jump hurdles, though this made not the slightest difference in the judges' opinion of him. He is a very bloodlike handsome nag, up to a certain weight, while Mr. Gardner's other horse, the winner of another prize in another class, has more power; and Mr. Tharp's Phalanx, the best hunter of any age, is also well up to weight; but beyond his bone and substance, there is little more to be said for him, as he has a thick, coacher's neck, with rolling, wooden action, and, according to Mr. Bennett, anything but a pleasant horse to ride. Amongst the second prize hunters were Mr. Long's four-year-old, and Mr. Durrant's clever old chesnut that took a prize as a hack at Downham. The two classes proper of hacks here were very poor, nothing beyond Mr. Worth's four-year-old being really worthy of notice, although three or four premiums were duly distributed. Mr. Worth won again with a good galloway; and Mr. J. L. King, of Wood Ditton, had a long way the best pony; while a premium for hackneys in harness also went to Mr. Worth, of Sutton; although the pairs were not much of a match, but then there was no competition. The special premium, offered by the town of Newmarket for a show in Newmarket of thorough-bred stallions to serve half-bred mares, also resulted in but one entry!—Mr. Jennings' German-bred King Pippin, by Blackdrop, out of Letitia, by Priam. The King is not much to look at; but then certainly he was not in show form, having had a very hard season, with the credit of getting some very good high-stepping stock. Mr. Jennings was first again for the best hack, but against lots of competition, and certainly with one of the cleverest and handsomest "nags" in the show. This was Amicable, otherwise Halifax, by Amsterdam, and himself quite thorough-bred. Some of the farmers grumbled a bit at his not being up to more weight, as with the 15 st. condition Mr. H. Martin's good cob that we missed at Downham no doubt would have won. But without the influence of any such clause it was impossible to ignore the fashion and action of the bay five-year-old. The moral of the riding-horse show was thus both with hunters and hacks that "blood will tell," and yet the Committee of the Cambridgeshire Society in the year 1868 continues to offer and award prizes to hunter stallions without pedigrees!

The Shire three-year-old, Mr. Welcher's Honest Tom, the best of his class at so many previous meetings, was the hero of the agricultural classes at Newmarket, taking the Society's premium of £10 for the best stallion, and the All-England Cup of £20 on the same showing. We can only repeat that he is a capital specimen of his breed, with power, action, and "appearance," and we know no cart-horse that is now more generally liked. In the first class Mr. E. Clayden, of Barham was second, with Lion, a fine-topped chesnut that could also move, and Mr. Harvey, of Mildenhall, third—three prizes for three entries. But in the open class, where Lion again competed, Mr. Badham was "next best" with his two-year-old Fitz Emperor, a colt that has much of the good and quite as much of the bad of his sire. In the Society's class of two-year-old stallions Mr. Mainprize, of Ely, was first with his nice Norfolk colt, and Mr. Gillings second with a bay, as indeed the chesnuts were not in such force. One of the best animals in the show for her purpose

was Mr. Warth's roan cart-mare, with power, weight, quality, and action all in her favour, and she walked clean away from her class; though Mr. Waltham was near enough to be placed second in fair company. The mares with foals at foot were nothing extraordinary, Mr. Gillings taking first prize with a rather neat, clean mare, and Mr. T. B. Harvey second. The one three-year old filly, although she was awarded the top prize, could not have won otherwise; and Mr. Wiles, of Denny, took first and second for two-year-old geldings on much the same terms—viz., there being no other entries beyond his own; Mr. Teulon's first prize two-year-old filly was much better, being both useful and handsome, but she had nothing but Mr. Gillings to beat; while the few foals were bad, with Mr. Ambrose first, and Mr. Gillings again second. There were no entries whatever of dray-horses, but there was a really good show of plough teams in pairs—hardy, well-grown, quick-stepping animals, that looked like getting through a fair day's work, and being ready again for another. Mr. Staples was first, with two very smart roans, and Mr. Taylor, of Soham, second, with a commendation for Mr. Peddar, of Kennet, and another good word for Mr. Nunn, who would have been more forward, but that one of his pair of cheanuts was lame. The best three-year-old colt, not entered in either of the two alleged classes, was a very good brown colt of Mr. Battcock's; the executors of Mr. S. Clayden getting the second prize with a light neat son of Chester Emperor; and the Suffolks were thus pretty generally but second-best.

There was a poultry show of rather limited range, and premiums of £10 and £5 for the best collection of implements, for which the following firms entered: Turner, Ipswich; Holmes, Norwich; Maynard, Whittlesford; Ransomes and Sims, Ipswich; Woods, Cocksedge, and Warner, Stowmarket; Baker, Wisbech; Ward and Silver, Long Melford; Wilkinson, Ely; Headly, Cambridge; and Cutlack, Ely. The award was in favour of Woods and Cocksedge first, and Ransomes and Sims second.

There was also prizes for grain, wool, and butter, which were thus distributed: Red Wheat: First prize, £4, T. Gardner; second, £3, not awarded. White Wheat: First prize, £4, L. Kent; second, £2, W. S. Peddar. Oats: No entries. Wool: Five fleeces of long-wool hogg, prize, £4, no merit. Five fleeces of short-wool hogg: Prize, £4, W. T. Brackenbury. Five fleeces of cross-bred wool hogg: Prize, £4, W. T. Brackenbury. Butter—Five pounds of butter, made up in one pound lumps, open to all England: First prize, £5, A. King; second, £3, Mrs. H. P. Balls.

The Judges were—Cart-horses: G. Bedford, Abbots Ripton; P. Portway, Great Sampford. Nag Horses: J. E. Bennett, Bosworth Grange, Rugby; T. K. M. Elliott, Heathencote, Towcaster. Cattle: W. Ladds, Ellington; J. Robinson, Clifton Pastures, Olney. Long-wool Sheep and Pigs: J. Codling, Whaplode; W. Looker, Wyton Manor, Huntingdon. Short-wool and Cross-bred Sheep: C. Howard, Biddenham; H. Thurnall, Royston. Implements: T. Gardner, Moulton; H. Long, Carlton. Grain: F. Challands, Newmarket; B. Colman, Newmarket. Wool: J. W. Turner, Westgate Hill, Bradford. Poultry and Pigeons: E. Hewitt, Eden Cottage, Spark Brook, Birmingham.

#### THE DINNER

Took place on the ground, with Lord George Manners, in the absence of the Duke of Rutland, in the chair. There was a very good attendance. In the course of the proceedings,

Lord HARDWICK said it would not be wrong on his part to give his opinion as to the future, and to dilate upon what were their agricultural prospects of making money. In the last

four years they had had a rapid ascent in the price of wheat. They would allow him to tell them what had been the condition of the wheat market, and what they might look for in the future, as no doubt it would be the case. They had had this year, in the month of March, wheat at an average of 72s. 10d. per qr.; in March, 1867, it was 60s. 11d.; at the same time in 1866, 44s. 11d. per qr.; and in 1865, 38s. 11d. Now he would tell them that the wheat market had reached its highest point; they knew it was now falling, and at least that was a warning to most of them. Why did he think so? America was rapidly quieting and increasing her growth of wheat; and to show them what she could do, though she had not been able recently, in 1861 she raised upwards of three hundred million quarters of wheat for the purpose, and she would do it again. They would have to consider, therefore, what they had to look for. In this year, and for the future, they must be prepared for a fall in the price of grain. That was a statement he conceived of some value (laughter). If they believed it they would be ready for it. His noble friend laughed heartily, and he was glad to see men amongst them who could laugh heartily at the prospect of a reduction of the price of wheat. As a landlord he was glad to hear that laugh, as it indicated the fact that the farmers were prepared to meet the fall in the price of wheat (laughter). His friend still laughed. He could only say that the gentleman represented the superlative of the farmer. When he cheered them with that happy laugh he gave them confidence in the tenant-farmer in the days that were coming upon them.

The CHAIRMAN said the Government had introduced a bill, which had not a political bearing, for the establishment of ports for the killing of newly-arrived meat, and that bill met with so strong an opposition that there was but little chance of its passing into law. Should that be the case, it would become imperative on agricultural communities not to rest till they had procured some security against these evils. Another question to which he would like to shortly call the attention of the meeting was the education of the agricultural labourer. Although he was far from thinking the general progress of education throughout the country unsatisfactory, yet there was no question that the education of the labouring classes did call for improvement (A VOICE: "How about the cottages?"). As far as he had been able to master the question, every boy before he arrived at the age of nine or ten—he should prefer ten—should have given him the necessary opportunity of obtaining sufficient education for his life. This was a subject that must be considered in future Parliaments, and he trusted that the decision arrived at would be a right one. Another point was one which came before them with peculiar claims at the present moment after a lengthened drought—*i.e.*, the water supply of the country. He could not but think that if some of the agriculturists were to place themselves in communication with some celebrated engineer, they might possibly in many districts obtain at a cheap rate, at all events, a limited supply of water, which would enable them to grapple with the very short supply they had now.

Mr. THURNALL said this was the fourth county show he had attended this year; and, so far as he could judge, it excelled the Bedford, and nearly equally the Essex and Bath and West of England shows.

Mr. HOLBEN, the secretary, said hitherto the Society had been unable to extend its operations to the labourer; but he had thought of laying before the committee a suggestion that they should offer a prize for the labouring man who produced a schoolmaster's certificate and proved that he had sent his children to school the most regularly and for the longest term. That would be an incentive or stimulant to self-denial.

Mr. T. JENNINGS, of Newmarket, responded for "The Successful Exhibitors;" and said that the emotions he felt at winning the prizes he had done that day were equal, or greater, than when he had won a great race; and he would endeavour on another occasion to have something better to show.

## THE NORTHAMPTONSHIRE AGRICULTURAL SOCIETY.

## MEETING AT OUNDLE.

It was quite evident one Thursday last month to the most casual observer, that something more than market-day was to come off at the snug little town of Oundle, rigged out as it was in holiday costume, like some grim warrior of the deep, with all its bunting flying. Indeed, every hatchway or loophole was crowded with smiling faces on the look out, as some Grand Seigneur in the form of a shorthorn bull, a bevy of cows, or a pen of sheep made their appearance, or, for what the Shire is still more famous, as some well-made hunter came sauntering along or gay hack went dancing by, who for step and neatness rivalled the lasses themselves; whilst old Dumphling's sleek well-fed looks and gaudy colours on either side the head were fairly outshone by the healthy rosy cheeks of some bouncing dairy-maid, and the flaunting ribands with which she had tied up her bonny black hair. On, on they go to the field of rivalry, to engage in the list for some of the thousand pounds given in prizes; while the banners idly wave in the air, and the cry is still "They come!" The show-ground was laid out close to the town, a beautiful site having been fixed on, and, viewed from the horse-ring or far end of the yard, surrounded as it was by clusters of trees, with the church rising from their very midst, formed a very pretty centre-bit. The strongest part of the exhibition being the horses, we made our way for the ring, which we think would have been better for all—judges, horses, and spectators—if it had not been quite so much on the slope; but this the steward who laid out the yard could not well avoid. The judging of riding horses, cart horses, beasts, sheep, and pigs, all commenced about the same time; and, although we much desired it, in vain we sighed "We would we were a bird," like Sir Boyle Roache, to be in two places at once. Several times we tried it on; but, finding that we were neither here nor there when anything important occurred, we gave up any further hopes of accomplishing an impossibility or bobbing at a cherry. In the hunting brood mares and foals the £20 brought an entry of sixteen; but, judging by many of the specimens sent, we should imagine their owners, like children who dip in a lucky-bag for a prize, trust more to fortune than judgment. The prize-mare is a brown deep-topped useful-looking one by Ambrose, and the highly-commended an old mare, with a capital forehead, but short from the whirlbone to the stifle, while her hocks are also somewhat stilty, and do not come well under her, without we were much deceived by the ground. Then next, with good looks, was the bloodlike chesnut by Monarque, from Mr. Cowper, of Leamington. Mr. G. Lyne's mare by Collingwood, with a foal by General Heas, very dicky in his forelegs, and Mr. P. Durran's mare were worthy of notice. In the hunting mares and geldings five years old and upwards, open to all England, there were some neat useful-looking horses, but nothing very much out of the way. The first prize, a chesnut by Kentucky, showing a deal of blood, is compact, well-made, with good ends, and his stifles well let down. If anything, he is a trifle short. He has a peculiar flourish with his hind feet, and, when trotting, picks his legs up a little too flashy for hunting, and more like reminiscences of Piccadilly. The highly-commended Old Port, bred at High Wycombe, Bucks, is of a good stamp, a neat, deep, well-made, short-legged horse that does not look like a very fast one, and that we think we could improve a bit in his shoulders,

if we had the remodelling of him for hunting-purposes. Thorpe Malsor, a placed horse here last year, was looking very well, and steered by his old pilot, whom we were sorry to see with his arm still strapped down by his side. Mr. Hill, of Oundle, showed a bay with a capital top that could move, but with hocks much disfigured by being capped, as well as bearing the marks of the iron. With Mr. Newcombe Mason up afterwards, he looked all over like going, and brought back to memory one who, as an elegant horseman and for crossing a country, "we shall ne'er look upon his like again." Mr. D. Bletsoe had a six-year-old black of very fair form, and Mr. G. B. Lynes and Mr. J. T. Roe had something pleasing. Mr. Colpman's Islip, Thrapstone, had a good top, but curby hocks; while the Hon. C. W. Fitzwilliam's chesnut mare's, by Affidavit, shoulders did not please us, or allow her to move. There was some taping going on in these classes; but without horses have the same quality, and are of the same build, we really scarcely see the use of it. Monarch by Lovett, in the four-year-olds, was a good-topped hunting-like horse; and the commended of Mr. Sharpe, also by Lovett, though not so grand in frame, is a clever light mover. Mr. W. Brooks had a fair-looking bay, with good limbs, that could go. Mr. Drage's bay gelding has a short neck, but a fair top, and is light below the knee; and Father Meurad, a big fair-looking blood-like horse, a little high on the leg, by Trumpeter, goes the rounds of the shows without collecting any halfpence. The judges picked out Mr. Hill's brown gelding, a compact horse, with just a dash of the cob in him, and his head set on throaty; as besides dishing with the off leg, he has a softish appearance, but they hung over him for some time. In the next class for riding-purposes we had ticked the winner off as a Tilbury, or light-carriage horse, and saw no reason, after looking him over, to alter it. He is a mealy bay, with not a very handsome nob. The second, by Mowbray, was a nice mare that could move; and the commended, a long-backed one, but more handsome than anything. The Hon. C. W. Fitzwilliam sent a brown by Richmond, with something taking about his top, but deformed in his forelegs; and Mr. T. Stokes had a useful one by Lovett. The gelding and fillies rising three were poor; the first, having his toes out and elbows in, is anything but a free mover; the second being a lathy bay of good form and breed. Mr. G. Jackson's thick compact-made chesnut, with blood, looked like making a light charger, as well as a handsome one when caparisoned. Some of the others were remarkable for their bad forelegs or shoulders being too forward. Mr. T. Roe's filly by Lovett had something of the hack about her, if not fashionable. In the colts and fillies we thought the young gentleman from the Land of Bucks by Ilder a long way the best, as he was taking in his looks with good big-jointed limbs. A filly by the Drake, out of Crazy Jane, was fair-looking. The hackney mares and foals under fifteen and an inch, were not a great class. At first the prize went to a mare by the Ugly Buck, a handsome, good-going hack, but she was disqualified, and the first place was then given to one of the "has-beens," in the shape of a varmint old mare by Pantaloon, four-and-twenty years old, and he must have been twenty when he got her, which will carry us back to the death of Louis the Eighteenth, or the laying the first stone of London-bridge. What a way a couple of old ones will

take you, if you only keep them together! The second to the old one was Jessie, a grey—a rather nice-looking little mare, with two stars on her knees, and not over-free in her movements; nor was Mr. E. Stokes's (Bulwick) old mare of great character, and she wanted a little oiling to set her going. Among the hacks not exceeding fifteen and an inch were some very neat ones. Mr. Lyne's mare, by Idler, dam by Skiff, being very good, with action and quality; while the second was a powerful chesnut, with symmetry and good strong action, but with a regular broomstick, with a few hairs at the end for a tail. However, as the rider does not see it, this is not of much consequence; without he happens to be acting as a judge; then, if he gets on one, the proper thing is to stand bolt upright in his stirrups, and look over the horse's shoulders to see if he can observe the animal's toes, and then repeat the same thing behind for his heels, taking especial care not to over-balance himself; having done this, he gets off, and is taken for a very knowing card. The commended was a neat bay of Mr. E. Stokes, of Wansford. The Rev. A. Longhurst had a very nice-shaped horse, a light hunter, by Ambrose, but who did not move so well; while Mr. W. Smith's, Oundle, brown, with a plain head, could go. The Rev. E. Grey's brown mare, Mr. J. H. Silby's brown mare, and Mr. J. D. Bletsoe's bay had something about them to take the eye. The cob winner was a really clever one, in shape and action, and is said to be by an Arab out of a Welsh pony, but she takes more after the dam. There was a little bay pony, a wonderfully quick goer, of Mr. W. Williams, of Oundle, and another Welshman, the pony we mean. Amongst the cart-horses, which, taking them altogether, were a very useful industrious-looking lot, and evidently not kept for show, there were many deep-topped, short-legged, active-looking horses, that would not let the grass grow under their feet. They were just on the move for home as we came round to them, so that we had no time to look them over carefully.

The beasts, both in the fat-stock and breeding classes, were well represented; Messrs. Robinson and Garne, excellent judges, pronouncing them to be an exceedingly good-looking lot—one saying that he would be much surprised if some of them did not obtain honours at the forthcoming exhibition of the Royal Agricultural Society at Leicester. In a class of six, Billy, a very level one, beat an ox, by Britannicus (17452) of Mr. Wood, well-known as the owner of a fat ox, who, after coming off victorious at Birmingham, was taken to the Crystal Palace, and made quite a peep-show affair of. In the steers, a good-looking white two-year-old and six months, by Lord Stanley Spencer (20823), ousted a two-year-old and six months exhibited by Lord Spencer. This naming animals after their breeders is apt to create confusion, and we can hardly see the compliment or taste when you hear the name of some nobleman coupled with a grand bull-like head, bad loins, no rump, and a tail fearfully set on. The Banbury cow was a nice neat-headed one, with quality, and exhibited in capital trim, her rival being also good-looking; while another, from the Burghly herd, came in for empty honours. These were the only competitors. A really nice-headed, level heifer, by Britannicus, carried off the cup, beating one of Lord Stanley Spencer's daughters, Clara, and two others, one coming from Thame, in Oxfordshire. Prizeman, the Downham best bull, was still in capital show condition; his other rivals will be found in the prize-list, all coming in for commendations, with the exception of the Hon. C. W. Fitzwilliam's Jasper. However, the M. P. was elected in the next class, with the rather leggy, ox-like Baron Windsor, second to the good-headed old Lord Chancellor, from Babraham. The six other competitors were not considered worthy of a commendation.

Cherry Butterfly (23550), out of a Duchess, is a very lengthy youngster, one year and nine months old, and considered to be the best animal in the yard, but he struck us as being a little hollow behind his shoulders—a hollow that later in the evening we wished we had had our heads in, having joined innocently enough what we took for an Ordinary, but which turned out to be an out-and-out *hip! hip! hip! hurrah* affair, with one cheer more, the noisiest dogs believing they were the most loyal. Really, we believe if our good little Queen had been there, knowing the kindly feeling she has for all her subjects, she would have addressed them in something after this manner: "Now, now, my good fellows; do pray stop this bawling and jumping up directly after dinner, like so many jacks-in-the-box. What good can this noise do our royal self, our children, our army, navy, bishops, or clergy, or what we take quite as much interest in, your noble selves? We do not doubt your loyalty for a moment, seeing it as we do written, crossed and recrossed, in every feature of your open manly countenance (loud cheers.) Do pray stop that noise; consider our royal head. My friends and subjects, do pray enjoy yourselves and your wine and the other good things we see the table covered with, in a rational manner. Let us hear again that pleasing hum throughout the room, caused no doubt, as we saw you gathered in knots of five or six, by cheerful conversation, interchanging ideas and gathering information before the gentleman at the top of room put an end to it by proposing our noble self (loud cheers.) Pray recollect yourselves; let us hear no more of it; we had imagined that in the march of civilization these noisy professions had gone out with the Bill for the Consumption of Smoke."

Grand Sultan, from what we could see with his cloth on, had length, quality, and handsome looks. He is by Prize-man, the first bull of any age. Jolly Queen, still on her travels, and Beauty had eight others to contend with, three or four, like themselves, being blessed with good looks. Queen of Rosalea proved the handsomest of the heifers by a long way; Mr. Pawlett, however, with a young Prince Hope-well, beating her half sister in the next class. Mr. How's red and white heifer of one year and ten months was declared the victress in a class of seven, including one of the Duke of Buccleuch's, and Victoria Spes, one of Lady Pigot's—dam Victoria Alba by Prince Alfred. So much for names. In a class of five, Mr. Pawlett's 11 months' heifer calf by Baron Killerby (23364) out of Rose Warlaby by British Flag (19351) was at the top of an entry of five; while Sir W. de C. Brooke's 1 year and 8 months' steer by Lord Stanley Spencer out of Amethyst by the Hero of Kara, in a class of four, carried out the saying of "the last shall be first," being at the bottom of the list. Sir William was first again in the next with Rose of Geddington, 1 year and 10 months, by Roger (24980), out of Rose of Ruby.

The sheep were strongest in long wools, most of the classes being well filled; while in the Down tops the Oxfordshire mustered very well. There were few entries in the classes for crossbreds and shortwoolled or half-bred. There was a poor show of pigs, while, on the other hand, the poultry was very strong.

## PRIZE LIST.

### RIDING HORSES.

JUDGES.—J. M. K. Elliott, Towcester.  
S. Middleton, Wansford.  
T. B. Tarnell, Wellingborough.

Mares and foals for hunting purposes, the foal to be by a thoroughbred stallion.—First prize of £30 to Mr. J. Cheasy,

Oundle (sire Ambrose). Highly commended: Mr. T. Tryon, Bulwick Hall (black).

Mares and geldings, five years old, adapted for hunting purposes (open to all England).—First prize of £20 to Mr. S. Ayres, Towcester (sire Kentucky). Highly commended: Mr. J. Drage, Moulton Lodge (Oldport).

Mares and geldings above four and under five, adapted for hunting purposes.—First prize of £20 to Mr. S. Gale, Kelmash (Monarch).

Geldings or fillies above three and under four, adapted for hunting purposes.—First prize of £7 to Mr. T. Bonsor, Oundle (sire Richmond); second of £3 to Mr. J. Smith (sire Mowbray).

Geldings or fillies above two and under three, adapted for riding purposes.—First prize of £7 to Mr. W. J. Cheney, Oundle (sire Richmond); second of £3 to Mr. H. Hunt (sire Northern Light).

Colts or fillies above one and under two, adapted for riding purposes.—First prize of £7 to Mr. J. Clode, Great Linford, Bucks (sire Idler); second of £3 to Mr. J. Lawrence, Elton (sire The Drake).

Hackney mares not exceeding fifteen hands one inch.—First prize of £7 to Mr. R. Ward, Uppingham (sire Pantaloon); second of £3 to Mr. S. Deacon, Oundle (Jessie).

Hackney mare or gelding not exceeding fifteen hands one inch.—First of £10 to Mr. G. B. Lynes, Preston Deanery (sire Idler); second of £3 to Mr. H. L. Bayley, Northampton (sire Criuk).

Cobs, mares or geldings, not exceeding fourteen hands high.—Prize of £5 5s. to Mr. J. H. Lowndes (sire an Arab).

Ponies not exceeding thirteen hands high.—Prize of £5 to Mr. J. D. Bletsoe, Grendon Hall, Notts.

#### CART HORSES.

JUDGES.—J. Bird, Yaxley, Peterborough.  
T. Wood, Witchly Warren.

Cart mares with foals at foot.—First prize of £10 to Mr. C. E. Tebbutt, Oundle; second of £5 to Mr. T. Baker, Weedon.

Cart geldings or fillies above three and under four.—First prize of £7 to Mr. J. W. D. Harris, Wootton (gelding); second of £3 to Mr. R. Wood, Clapton, Thrapstone (filly).

Cart gelding or filly above two and under three.—First prize of £7 to Mr. R. Timms, Ragby (gelding); second of £3 to Mr. T. Baker, Weedon (filly).

Cart yearlings, geldings or fillies.—First prize of £5 to Mr. E. Winder, Clapton Hall (filly); second of £3 to Mr. R. Timms, Ragby (gelding).

#### BEASTS.

JUDGES.—G. Garne, Chipping Norton.  
J. Knowles, Wetherby.  
J. Robinson, Clifton Pastures.

Fat stock, open to all England.—Oxen exceeding three years and three months on the 1st December next, without restriction as to keep, though the kind of food is to be certified.—First prize of £10 and cup to Mr. C. Speed, Exton (Billy); second of £5 to Mr. R. Wood, Thrapstone (sire Britannicus). Highly commended: Mr. T. Pulver, Broughton, Kettering.

Open to all England.—Steers not exceeding three years and three months on the 1st December next, with same condition as to food.—First prize of £10 to Sir W. de Capel Broke, Geddington Grange; second of £5 to Lord Spencer. Highly commended: The Marquis of Exeter. Commended: Mr. J. How, Broughton, Hunts.

Open to all England.—Cows of any breed or age (same condition as to keep).—First prize of £10 to Mr. J. Ivens, Banbury; second of £5 to Mr. W. Spencer, Hinckley.

Open to all England.—Heifers of any breed, not exceeding four years old on Dec. 1 next (same condition as to food).—First prize of £10 to Mr. R. Wood, Thrapstone (sire Britannicus); second of £5 to Sir W. de Capel Broke (Clara); commended, Mr. R. E. Oliver, Towcester.

Breeding and store stock, open to all England.—Bulls of any age.—First prize of £20 to Mr. J. Lynch, Stroxton, Grantham (Prizeman, 24870); highly commended, Mr. T. E. Pawlett, Beeston, Beds (Baron Kilerby), and Lady E. Pigot (Charles le Beau); commended, Sir W. de Capel Broke (Lord Stanley Spencer).

Bulls above two years old, the property of or hired by the exhibitor, that has proved himself a stock-getter, which shall have been or is to be used in the county.—First prize of £15 to Mr. R. Wood, Thrapstone (Lord Chancellor, 20160); second of £5 to Hon. C. W. Fitzwilliam (Baron Windsor).

Bulls above one and under two years of age, which shall have been or is to be used in the county.—First prize of £15 to Mr. R. Oliver, Towcester (Cherry Butterfly, 23550); second of £5 to Sir W. de Capel Broke (Duke of Wateringbury, 23790).

Bull calves above six and under twelve months old.—First prize of £10 to Mr. J. Lynch, Stroxton (Grand Sultan); second of £5 to Mr. R. E. Oliver, Towcester (Cherry Grand Duke); highly commended, E. Freeman, Thame, Oxon.

Best cow of any breed, in-milk or in-calf.—First prize of £10 to Mr. J. How, Broughton, Hunts (Jolly Queen); second of £5 to Mr. C. J. Bradshaw, Burley-on-the-Hill (Beauty); highly commended, Mr. C. Speed, Exton, Oakham (Diana), Sir W. de Capel Broke, Geddington Grange; commended, Mr. S. Deacon, Oundle (Emma).

Heifers of any breed, in-milk or in-calf, above three and under four years old.—First prize of £10 to Lady E. Pigot (Queen of Rosalea); second of £5 to Mr. Selby, Oundle.

Heifers of any breed, in-milk or in-calf, above two and under three.—First prize of £10 to Mr. T. E. Pawlett, Beeston, Beds; second of £5 to Lady E. Pigot (Dame of Rosalea).

Heifer of any breed, above one and under two years.—First prize of £10 to Mr. J. How; second of £5 to Mr. T. E. Pawlett; commended, Mr. C. Speed, Exton, Oakham, (Polly).

Heifer or calf of any breed, under 12 months.—Prize of £5 to Mr. T. E. Pawlett.

Shorthorn steer, under two years.—First prize of £5 to Sir W. de Capel Broke.

Shorthorned heifer, above one and under two years, to have been in the possession of the exhibitor for six months previous to the show (open to the above subscribers and to all members of the society residing in the county).—Prize of £20 to Sir W. de Capel Broke (Rose of Geddington).

#### SHEEP AND PIGS.

JUDGES.—T. Jones, Wellingborough.  
J. Painter, Nottingham.  
T. Wagstaff, Peterborough.

Pens of ten long-woolled ewes, that have suckled lambs to June 1, 1868.—First prize of £10 10s. to Mr. J. Gillett, Charlbury; second of £5 5s. to C. J. Bradshaw, Oakham; highly commended, Mr. R. Barlow, Oundle, and Mr. W. Godfrey, Oundle.

Pens of five long-woolled ewes.—First prize of £5, to Mr. J. Giblin; second of £2 10s., to Mr. C. Hales; commended, Mr. C. F. Bradshaw, Alstoe, Oakham.

Pens of five cross-bred ewes, that have suckled lambs to June 1, 1868.—First prize of £5, to Mr. J. Treadwell, Winchendon, Bucks.

Pens of three cross-bred shear hogs.—First prize of £5, to E. Freeman, Thame, Oxon; second of £2, to Mr. F. Street, Bedford.

Pens of three long-woolled shear hogs.—First prize of £5, to Mr. J. Edwards, Buckworth, Kimbolton.

Shearing long-woolled tups.—First prize of £5, to Mr. J. Gillett, Charlbury; second of £3, to W. F. Marshall, Branston, Lincoln; commended, Mr. J. Gillett.

Long-woolled tups of any breed, two shear and upwards, that has proved himself a stock-getter.—First prize of £7, to Mr. J. Lynch; second of £3, to Mr. W. F. Marshall, Branston, Lincoln; commended, Mr. J. Gillett.

Down tups of any age.—First prize of £7, to Mr. J. Treadwell, Winchendon, Bucks; second of £3, to Mr. J. Giblin, Bardfield, Essex; commended, Mr. F. Street, Harrowden, Bedford.

Pens of five long-woolled wether lambs.—First prize of £3, to Mr. T. G. West, Dallington, Northampton.

Pens of five long-woolled ewe lambs.—First prize of £3, to Mr. T. W. Harris; second of £1 10s., to Mr. J. Gillett.

Pens of five short-woolled or half bred wether lambs.—First prize of £3, to Mr. J. N. Beasley, Brampton, Northampton.

Pens of five short-woolled or half bred ewe lambs.—First

prize of £3, to Mr. J. Longland, Grendon, Northampton; second of £3, to Mr. J. N. Beasley, Brampton.

Boars of any breed to be used in the county.—First prize of £5, to Mr. J. A. W. Underwood, Oundle; second of £2, to Mr. S. Deacon, Oundle.

Sows breeding or suckling, of any breed.—First prize of £5, to Mr. S. Deacon, Oundle; second of £2, to Mr. Yorke, Holdich; commended, Mr. J. Wheeler, Shipston-on-Stour.

Pens of three fat pigs, of any breed or age.—First prize of £5, to Mr. R. Wood, Thrapstone; highly commended, Mr. J. Giblin, Bardfield, Essex.

Five breeding pigs of one litter, above three and not exceeding six months old.—Prize of £5, to Mr. R. Wood.

#### IMPLEMENTS.

Prizes awarded to exhibitors: Amies and Barford, for general collection of reapers and mowers £3, for rollers and crushers £2, for improved large cake crushers £1, and their general

collection was highly commended. To Ball and Son, Rothwell, for collection of carts and waggons for agricultural purposes £3; for an improved scuffer £1. To Hayes and Son, Stamford, for a collection of carts and waggons for agricultural purposes, £2. To Richmond and Chandler, Manchester, for an improved large chaff-cutter, £2. To Ashby and Jeffery, for a small chaff-cutter £1, their improved haymaker highly commended. To Smith and Grace, Thrapston, for bean and oat mill £2, for small chaff-cutter £1. To T. Corbett, for an improved winnowing machine, £1. To Chapman, of Apethorpe, for collection of carts and waggons £1, break and cart highly commended. There was a trial of mowing machines, which took place in a meadow low and moist, where the work was excellent. There were five competitors: Hornsby, Kearsley, Samuelson, Burgess and Key, and Wood, of Upper Thames-street. The first prize of £10 was awarded to Samuelson, whose machine cut the allotted acre in 45 minutes; and the second of £5, to Woods, whose American machine did the same amount of work in 43 minutes.

## THE SUFFOLK AGRICULTURAL ASSOCIATION.

### MEETING AT FRAMLINGHAM.

The Suffolk Association, blessed as it is with its park at Ipswich and the old castle grounds at Framlingham, two of the prettiest show-yards in the kingdom, and ranking, as it does, as one of the oldest of our agricultural societies, does not with years appear to increase in stature, but, on the contrary, is evidently on the wane. This downward tendency is easily traced to a want of spirit equal to these go-ahead times, as well as to a want of liberality. Indeed, the Suffolks can be tempted into an adjoining county to carry off a twenty-five or a twenty-pound prize, while at home they in return barely offer sufficient to pay for the seed cake and sherry, so necessary for the successful exhibitors' friends who come to do homage to the prize animal on his return to his stall. Several old members, on discussing the subject, came to the conclusion that they did not see why they should not be able to get up as good a prize list as that of their neighbours in Essex; and the chairman, as will be seen, spoke very pointedly to this at the dinner. The ground was nicely laid out with canvass sheddings, for the horses, cattle, sheep, and pigs, that afforded plenty of protection from the sun, which was scorching and no mistake; while the two rings, for judging the riding and agricultural horses, adjoined each other, and enabled one to see what was going on in both, besides affording a most agreeable relief to the eye from that monotonous study of red and all-red—a colour that the agriculturists of Suffolk, in spite of the old adage, think it absolutely necessary that a good one should be. To save people from unnecessary feats of pedestrianism, in following each class to their standings, to get at the winners, the numbers might be hoisted in the ring after each award. Even the strong feature of the show, the red and all-red, good as they still are, were not up to what we have seen, although the twenty pounds divided into three prizes brought a very excellent class, and several well-known prize takers, including the first and second at the Royal Bury show last year, but who now reversed their position or something more, as the compact, well-built, short, stout-limbed, active looking Cupbearer was first, whilst Mr. Bobby's Conqueror, with his over-created neck, set on as if part and parcel of something else not belonging to him, was, with his weak arms and thighs, nowhere. The second was a well-knit one, bred by Mr. Bromley, by Wolton's horse; but more to our fancy, barring his feet, was another compact, well-built animal, bred by Mr. Gentry, and foaled in 1861. Why the

names of these horses are not put down in the catalogue we should much like to know, as what with Conqueror this and Emperor that over and over again, with f. s. d., s., or b. tacked on, and in one place a five year-old and another six, is enough to muddle the head of a Porson without the drink, or a Bidder without the addition of figures. Mr. Rist's Harwich Emperor, whose forelegs we were not in love with, had met with some accident, and was disqualified this time without giving him the benefit of a doubt. The other competitors were G. Estaugh's Marquis, E. Cavell's Victor, and S. Wolton's Monarch, the fight being between Mr. Rist's horse, and Mr. Crisp's three. How long the judges hung over this class before calling in a referee to decide for them, we will not say; but this we will say, it was unpardonable. In the three-year-olds the Bury decisions were again reversed. In the two-year-olds there were some good specimens of the Suffolk, the Woodbridge colt being a fine-grown and very forward one. The yearling entire colts were good, though few, two having prizes and the other commendations. There were only two *gast* or barren mares—the nice-looking deep-topped Moggy, by Canterbury Pilgrim, and the useful good-limbed Matchett by Hercules; while in the three-year-old fillies Mr. Wolton had it all his own way, the good-looking young Matchett, commended in Essex, having nothing to oppose her: Bonny, by name and nature, though blessed with that abomination in horse-flesh so common to most of the Suffolks, the calf-knee, or in other words, perhaps more appropriate, being back at the knees, was the best two-year-old. We saw a thorough-bred whose legs inclined the same way, through mere sympathy, and a short residence in the county; for his great ancestor's legs were all the other way. Duchess, by Bobby's Conqueror, the second to Matchett, was thought by many to be quite her equal; while a known good judge, who had carefully looked her over, declared he quite agreed with the verdict. The yearling fillies were poor, with only three competitors for the two prizes. There were also the same number of geldings of any age, the prize-horse being an eight-year-old, a lengthy deep horse, on a short leg, by Capon's Duke. The winning pair of cart-geldings were very good-looking, and the highly-commended useful, and from appearance seeming as if they belonged to a self-supporting club, which is more than we can say of most of the others, idleness apparently having clothed them not in rags, but in

burdens of fat. Is not this fattening carried a little too far? Matchett and Dapper, a pair of cart mares, were as handsome as anything in the yard; but, as "handsome is as handsome does," they did not look like work-a-day folks.

In the thorough-bred stallions, Captain Barlow, who has done so much for the breed of horses in the county, and who has still his work cut out for him, through a slice of luck this time became possessed of the enormous sum of ten pounds with King of the Dale, and seed-cake and sherry will be in the ascendancy at Hasketon; his only opponent Beauville, led by a son of old Martin Starling, whose face of the roseate hue, well-filled scarlet, cords, and tops, must be familiar to millions who have seen one of the sights of the world—a Derby-day. Beauville was disqualified, having a contracted hoof. He is a brother of Rapid Roan, and of the same colour, bred by Lord Glasgow and exhibited by Lord Stradbroke, and is really a neat clever lengthy short-legged thoroughbred horse, without lumber. He has good ends, is a trifle slack in his back, with good short-jointed limbs from the knee and hock down, that have seen some knocking about; but his good head is set on fearfully throaty to a rather peacocky neck. There was no opposition in the coaching or roadster stallions, there being a prize for each, and one over; but we will not say they were properly placed. A good stamp of mare won in a poor lot of hunting mares with foal at foot, and a neat dappled brown in a poorer sample of coachers. Then in the cob mares there were some clever hacks; but the only one that could come under the definition was old Gipsy, the dam of Silver Locks, the prize hunting mare at Bury; and also of Lucifer, a well-known "Brummagem" prize cob. Mr. Crisp exhibited a varmint old chesnut hackney; Mr. Groat, a strong, useful, moving one; and Mr. Rackham, a neatish one, rejoicing in one of the old-fashioned names of our great great grandmothers, not Hannah Maria, but Mary Jane. The hunting and coaching foals were both by the disqualified Beauville, and the roadster by Quicksilver Shales. Of the weight-carrying three-year-olds, as hunters, the less said the better; for Mr. Easterton's Fitz-Weatherbit, by Weatherden, was the only one with shoulders approaching his purpose. In the hackney mares or geldings the prize went to a vulgar-looking clod-crusher, suitable for an explorer, traps and all; or to come in generally useful in case of a scarcity of beef. Alice is a neatish hack and a mover, but a little raw in her manners; while a lathy black, with a fiddle head set on to his neck like a case, moved in grand style. There were three others very fair—Mr. Capon's, Mr. Barker's, and Mr. Borrett's. In the hunting mares or geldings were two or three neat ones, but the class was more remarkable for a good-looking, hunting-like roan; a would-be musical gentleman being disqualified for an attempt to hum "Gentle Zetella" or "Not for Joseph"; and the two more fortunate Brewers. The coaching gelding, Dandy, is a stylish-looking animal; and Polly, a neat pony, with power. Rufus, who carried off the Framlingham Hunter cup, is a good stamp, with breed—rare old head and limbs, though all humility about the knees, having seen some service in the quarter of a century he has been permitted to roam. He belonged at one time to Mr. Tharpe, near Newmarket, and, no doubt, matriculated at Cambridge. Mystery is a neat short-jointed hunting mare, Mr. Groat's bay of some character, and Mr. Gayford's Charley a neat hack.

The show of cattle was small indeed, numbering as it did but thirty head. What would old Rhodes, not the statue, but the dairyman, when Camden Town was in fields, have thought of such an exhibition, when his own cows often numbered nine hundred and ninety-nine, but never reached a thousand? Or at least, so says tradition. The Polled

Suffolks, with which we were much pleased, were in the greatest force (red and all red again), having among them some really handsome bloodlike little toys. With a sirloin from one and a saddle from the Elmham Hall flock, we think, any one might manage to rought it. King Alfred, a polled Suffolk, is very neat; but Rendlesham Hero, though handsome, has rather a big head, which gives him a Tom Thumb, or dwarfish appearance. In the cows, Sprightly, from the Rendlesham herd, with a beautiful top and quality, beat a pretty one from Mr. Tomline, who exhibited some very clever things, both in horses, cattle, and sheep. Favourite, the silver-medal cow at Downham, came in for empty honours only. In the three-year-old heifers, with three entries, Violet 2nd had plenty of quality, of which Red Stockings was not deficient; Sir Edward Kerrison being again to the front, with a level stylish heifer of quality, in a match with one Mr. Tomline's. Of Shorthorns there were not half-a-dozen, and but one pedigree bull amongst them, excepting Mr. Cooper's bull from Pencraig, and he does anything but justice to that herd; though he landed a prize with nothing against him. Sorcerer, the good-looking county bull at Chelmsford, had no trouble in disposing of Mr. Crisp's, who, though a neat one, falls off in his hind-quarters. Three cows in milk, a fat heifer, and two fat oxen, a neat polled pair of Mr. Wolton's, and two pairs of horned cows made up the total.

The sheep were but a handful, many of the classes being represented by an entry or two only. But the most remarkable fact was Mr. Tomline beating Lord Sondes with his own blood in the shearing tups; while in the tups of any age there was a capital representative from Elmhall Hall. In the shearing ewes Lord Sondes had two very nice pens, but Mr. Tomline managed to score a second with his only entry, and in the short-woolled shearlings was first without opposition. Mr. Gayford, with some half-breds, was unopposed in the pens of twenty, both in the wether and ewe lambs, though his sheep were but in poor trim. With blackfaces Messrs. Dobito, Green, and Harvey were the only exhibitors, excepting a troupe of Negro melodists, with banjo, bones, and eccentric costumes, and, like the sheep, anything but a matchy lot.

The pigs were few in numbers, but good in quality, coming, as they all did, with the exception of a couple of pens of Mr. Sawyer's, from two well-known breeders; and the prizes went, when there was any opposition, pretty much as you would have introduced those two well-known gentlemen, "Mr. Stearn, Mr. Crisp—Mr. Crisp, Mr. Stearn;" or like we have seen before now, a couple *vis-à-vis*, armed each with a black bottle, when so much wine was included in the dinner-ticket, and it was considered necessary to put on a pretty laugh, bob the head like a couple of Mandarins, and repeat each other's names before drinking a glass of wine—"Mr. Crisp, Mr. Stearn—Mr. Stearn, Mr. Crisp." In the black sow and pigs and white sow and pigs, and pens of three black sows and three white there was no opposition, and in the pen of five breeding pigs Mr. Stearn was opposed by Mr. Sawyer only. The other classes were matches between Mr. Crisp and Mr. Stearn, but with odds or entries in some cases of three to one on the former. Lady Elizabeth—unfortunate name!—a black sow of breed with a narrow back and a tucked-up appearance, was not liked so well as Mr. Crisp's second by the "olloi piggoi," and, we believe, the judges were not quite unanimous as to the verdict.

The bells rang merrily as we came away, and crowded Framlingham, to all appearances, was the happiest of the happy, and gayest of the gay. But what a pity there was not a more liberal prize-list!

## PRIZE LIST.

## AGRICULTURAL HORSES.

JUDGES.—W. Bloomfield, Hockwold, Brandon.  
A. Freyer, Debenham.

Stallions having served not less than twenty mares in the county.—First prize of £10 (cup bearer), and second of £5, to T. Crisp, Butley.

Three-year-old stallion.—First prize of £6 to T. Crisp; second of £5 to W. Wilson, Baylham (President).

Two-year-old stallion.—First prize of £5 to J. Grant, Woodbridge; second of £4 to W. Wilson; third of £3 to C. Boby, Stutton (Captain). Highly commended: J. Sawyer, Tunstall (Duke).

Yearling colts.—First prize of £5 to G. Tomline, Orwell Park; second of £3 to W. Wilson, Baylham. Commended: S. Wolton, Newbourn, and T. Crisp.

Mares and foals.—First prize of £6 to S. Wolton, jun., Kesgrave (Violet); second of £4 to G. Tomline (Darby).

Foals.—First prize of £5 to D. Capon; second of £3 to T. Crisp. Commended: S. Wolton, Kesgrave.

Mares.—First prize of £6 to W. Borrett, Framlingham (Moggy); second of £4 to J. Catchpole, Letheringham (Matchett).

Three-year-old fillies.—First prize of £6 to S. Wolton, jun., Kesgrave (Matchett).

Two-year-old fillies.—First prize of £5 to G. Tomline (Bonny); second of £3 to A. Noble, Creeting (Duchess).

Yearling fillies.—First prize of £4, and second of £3, to S. Wolton.

Geldings of any age.—Prize of £4 to T. Capon (Bowler).

Pairs of geldings.—Prize of £8 to T. Easterton, Bawdsey.

Pairs of Mares.—The Cup to T. Capon (Matchett and Depper). Commended: Mr. S. Wolton (Diamond and Depper).

## RIDING AND COACHING HORSES.

JUDGES.—Capt. Blake, Claydon.

H. Overman, Weasenham.

Thorough-bred stallions.—First prize of £10 to Captain Barlow (King of the Dale).

Coaching stallions.—First prize of £10 to J. Grout, Woodbridge (Harkaway).

Roadster stallions.—First of £10 and second of £5 to J. Grout.

Hunting mares and foals.—Prize of £5 to T. Crisp.

Coaching mares and foals.—Prize of £5 to F. G. Freeman (Rainbow).

Cob mares, fourteen hands high and not exceeding fifteen hands.—Prize of £4 to Captain Barlow (Gipsy).

Hunting foals.—Prize of £4 to F. G. Freeman, Reyden (roan).

Coaching foals.—Prize of £4 to F. G. Freeman (roan).

Roadster foals.—Prize of £4 to R. V. Sutton (bay).

Three-year-old weight-carrying mares or geldings for hunting purposes.—Prize of £5 to G. Fish, Campsey Ashe.

Three-year-old coaching mare or gelding.—Prize of £5 to N. Welton, Bredfield.

Three-year-old roadster mares or geldings.—Prize of £5 to J. Garnham, East Stonham (bay).

Two-year-old mares or geldings for hunting purposes.—Prize of £4 to M. Mumford, Creeting (Queen of Clubs).

Hackney mares or geldings.—Prize of £5 to F. G. Freeman (Norfolk); second of £3 to J. Grout (Alice).

Hunting mares or geldings.—First prize of £5 to E. Green, Irworth (Brewer); second £3 to J. Grout (Brewer).

Coaching mare or gelding.—Prize £5 to J. Grout. Highly commended: T. Easterton (Bawdsey).

Ponies not under twelve hands and not exceeding thirteen-and-a-half hands high.—First prize of £4 to J. Grout (Polly); second of £3 to N. Catchpole, Ipswich (Tom).

Hunters of age, regularly hunted in the county last season.—Silver Tankard to Rev. A. Bond, Friston (Rufus); extra prize to T. Capon (Mystery).

## CATTLE.

JUDGES.—J. Claydon, Littlebury.  
T. Fulcher, Elmham.

Suffolk bulls under two-years-old.—First prize of £4 to

Lord Boudlesham (Hero); second of £2 to G. Gooderham, Monewden (King Alfred).

Suffolk cows, in milk or in calf.—First prize of £5 to Lord Rendlesham (Gem); second of £3 to G. Tomline (Pretty). Highly commended: S. Wolton (Favourite).

Suffolk heifers, three-year-old, in milk or in calf.—First prize of £4 to Sir E. C. Kerrison (Violet 2nd); second of £3 to G. Gooderham (Red Stockings).

Suffolk heifers, two-year-old, in milk or in calf.—First prize of £4 to Sir E. C. Kerrison (Princess); second of £2 to G. Tomline.

Bulls of any other breed, not under two-years-old.—First prize of £6 to J. Upson (Sorcerer); second of £3 to T. Crisp (red and white Shorthorn).

Bull of any other breed under two years old.—Prize of £4 to G. K. Cooper (Euston).

Cow of any breed but Suffolk, in milk or in calf.—First prize of £5 and second of £3 to N. Catchpole, Ipswich.

Fat heifers, not exceeding three-years-old.—Prize of £2 to W. Thurlow, Hacheston.

Pairs of polled cows, of any breed, for dairy purposes.—Prize of £4 to S. Wolton (Heiress and Cowslip).

Pairs of horned cows.—Prize of £4 to T. Capon, Dennington (Polly and Nancy).

Fat ox of any age.—Prize of £4 to J. Upson (Prince).

## SHEEP.

JUDGES.—O. Hawkins, Colchester.

C. Howard, Biddenham.

Southdown tups of any age.—Prize of £6 to Lord Sondes.

Southdown shearing tups.—First prize of £6 to G. Tomline; second of £2 to Lord Sondes.

Tup of any age of the Suffolk black-faced breed.—Prize of £6 to J. M. Green, Stradishall.

Shearing tups of any age of the Suffolk black-faced breed.—First prize of £6 and second of £2 to J. M. Greene.

Pens of five Southdown shearing ewes.—First prize of £6 and second of £2 to G. Tomline.

Pens of five shearing ewes of the Suffolk black-faced breed.—First prize of £6 and second of £2 to G. King, Gazeley.

Pens of five short-wooled shearing wethers.—Prize of £3 to G. Tomline.

Pens of twenty wether lambs of any breed.—First prize of £4 and second of £2 to G. Gayford, jun., Rymer House.

Pens of twenty ewe lambs of any breed.—First prize of £4 and second of £2 to G. Gayford.

## PIGS.

JUDGES.—O. Hawkins, Colchester.

C. Howard, Biddenham.

Pigs.—Boars of the black breed.—First prize of £5 to S. G. Stearn, Brandeston (Black Tom), and second of £3 to T. Crisp.

Boars of the white breed.—First prize of £5 to T. Crisp, and second of £3 to S. G. Stearn, Brandeston.

Sow and pigs of the black breed.—First prize of £4 to S. G. Stearn.

Sow and pigs of the white breed.—First prize of £4 to J. Sawyer, Tunstall (Victoria).

Breeding sows of the black breed.—First prize of £3 to G. S. Stearn (Lady Elizabeth), and second of £3 to T. Crisp and highly commended.

Breeding sows of the white breed.—First prize of £3 and second of £2 to T. Crisp. Highly commended: G. S. Stearn (Lady Caroline).

Pens of three sows of the black breed, pigged since Nov. 1st.—Prize of £3 to S. G. Stearn.

Pens of three sows of the white breed.—Prize of £3 to S. G. Stearn.

Pens of five pigs, not exceeding four-months-old, for breeding purposes.—Prize of £4 to S. G. Stearn.

## THE DINNER.

At the dinner, which was not so well attended as heretofore, Sir EDWARD KERRISON, the Chairman, said, in proposing "Success to the Suffolk Agricultural Association," he had not himself been able to see the show of that day, but general report told him that though not at all equal in numbers to the shows of former years, it was very good indeed in quality.

There were circumstances which necessarily rendered this show small. For two years they expected the show of the Royal Society to be held in the county—for one year in vain; and when it was held, it was held without cattle. During those two years, no one would subscribe to the Suffolk Society, which was going to give its funds in a lump to the Royal Society. Another reason why the show was small was the smallness of the prizes. He believed if the spirit of the county were roused that they would be equal to the occasion; and he hoped that no feeling that the labourers should be dissociated from the society would be allowed to prevail. Let them see whether they could raise the funds; and at another meeting there would be prizes enough to induce people from a distance to come to the Suffolk show. They must not be discouraged because Norfolk and Essex had a large show, and Suffolk not so good, for there were 100,000 more inhabitants in Norfolk, and the same number more in Essex, than in Suffolk; and in Norfolk there were 50,000 more cattle than in Suffolk, and 200,000 more sheep, and they could not expect the same number of animals at the show of one county that there was in the other. Agriculturally speaking, they had had a year of considerable difficulty; it was not to them alone, but to the country at large. The deficiency of wheat to be met in this country was twenty-seven millions. That was to say, last year they had to pay twenty-seven millions more money for foreign corn than was wanted in 1863, when there was the largest harvest for twenty years. What the effect must be upon the country he could not say, but it was satisfactory to know that, by energy and continued activity, the agriculturists, by superior management of the land, were enabled quickly to make up the loss occasioned by a bad harvest in comparison with France, where only 15½ bushels per acre were produced against 28 in England; and although the deficiency between 1863 and 1867 was as much as 14 bushels an acre, they would perceive what energy could do. Still they knew that further exertions were necessary if they meant to keep up in the race with foreign competitors. The average supply of wheat annually wanted was twenty million quarters;

and last year the quantity produced was only nine millions, the rest having to be supplied from abroad. England took the first place in the agricultural department of the Paris Exhibition. Last year, at the Royal Society's Show at Bury, they saw some 4,000 implements: the show was very interesting; and there were, what he thought essential, prizes for the best implements, so as to enable agriculturists to know which were the best. At that show they saw the steam plough, and he would say that it would be some time before they ploughed by steam in this country, for two generations of farmers had dug ditches, which it would take another generation to get rid of, and they must be got rid of before they could avail themselves of steam. But when they remembered that the Viceroy of Egypt had more steam ploughs than were in use in the three or four eastern countries—

Mr. R. GARRETT: More than in all England.

Sir E. KERRISON: Even more than in all England. He thought when they thought of this, it was time for them to consider whether they could not use them with advantage. The question with reference to the labourers had arisen; and he should be indeed sorry if they dissociated them from the society, for the interest of all—landowners, occupiers, and labourers—was one. He referred to the subscription paid by the working-classes to friendly societies and clubs, and to the efforts they made to avoid becoming a burden to the rates; and he asked how could they do greater good than by trying to assist these honest labourers in their endeavour to provide for the day of sickness and for old age? It was a question, not of charity, but of positive expediency. He condemned the attempt to get the agricultural labourers to form a trades' union, pointing out the agricultural labourers had a large number of different occupations; and he advised employers to try to keep the younger portion of the labourers in their employ by paying more according to the amount of work each man accomplished, than by paying day-wages. He concluded by expressing his hope that however they might raise the prizes for stock, they will do so without interfering with the rewards they offered to labourers.

## RIPON AND CLARO AGRICULTURAL SOCIETY.

The show of this society was held on July 7th, for the first time after an intermission of the annual competition for three years. This cessation was solely attributable to the prevalence of cattle plague, and to the influence of measures taken to stamp out the pestilence. At the show on Tuesday there was once more an excellent display of cattle, a class of stock which invariably divides with horses the interest of an agricultural exhibition. The entries of cattle were 71, of horses 196, of sheep 43, of pigs 33, of poultry &c. 185, and of implements 187. Amongst the cattle shown there were some fine specimens of shorthorns; but this is scarcely matter of surprise when a glance at the catalogue revealed the names of so many noted breeders, several of whom reside within the district of the show. Sheep and pigs were both well represented, and the display of implements included everything required by the farmer, the collection of reapers, as might be expected at this season, being especially large. On this occasion, however, the horses were really the leading feature of the show, there being upwards of 100 entries; and seeing that that was the district hunted by the York and Ainsty, and the Bedale packs, every one was prepared for some fine specimens of hunters. Lady Derwent, the winner of the first prize for the best hunter, took the gold medal at Islington.

### PRIZE LIST.

JUDGES.—Horses: W. Godson, Normandy-by-Stowe, Gainsborough; R. Botterill, Garton, Driffield; J. Johnson, Brigham, Driffield; T. Ellerby, Whitwell, York.  
Cattle: H. T. Peacock, Mount Vale, York; T. Wetherhill, Claypath, Durham.  
Sheep and Pigs: T. Stamper, Highfield House, Oswaldkirk; C. Wright, Oglethorpe Hall, Tadcaster.  
Poultry: G. Hutchinson, Prospect House, York; J. O. Jolly, Green Hamerton.  
Implements: C. Clark, Minakip Lodge, Boroughbridge.

### CATTLE.

Shorthorn Bull, two years old or upwards, £5, W. Linton, York; second, £2, J. W. Botcherby, Darlington; third, £1, J. and J. Bulmer, Darlington; highly commended, J. Yorke, Pateley Bridge. Bull, above one and under two years old, £3, Wm. Linton; second, £2, J. Greenwood, Ripley; third, £1, A. Stables, Richmond; commended, R. J. Hudson, Burley-in-Wharfedale. Bull calf, under twelve months old, £2, S. Frank, York; second, £1, J. Smith, Wetherby; commended, T. H. Hutchinson, Catterick. Cow or Heifer, in calf or milk, three years old and upwards, £3, J. Greenwood; second, £2, W. Linton; third, £1, M. Thomlinson, Wetherby; highly commended, J. W. Botcherby, J. Edmondson, and H. Powell, Ripon. Heifer, in calf or in milk, under three years old, £2, W. Wilson, Burton Leonard; second, £1, S. H. Powell. Heifer, one year old and under two, £2, J. W. Botcherby; second, £1, G. Yeats, Ripon; highly commended, J. T. Pearson, Leeds. Heifer calf, under twelve months, £1, R. J. Hudson, Burley-in-Wharfedale; second, 10s., R. Pearson, Hutton.

CATTLE OF ANY BREED, OR A CROSS.—Cow, for dairy purposes, £1 10s., R. E. Collinson, Ripon; second, £1, M. Steel, Wath; third, 10s., G. Yeats, Ripon.

### HORSES.

Brood mare for the field, £2, J. Lancaster, Cleveland; second, £1, T. B. Maynard, Marton-le-Moor; third, 10s., S. H. Powell, Ripon. Brood mare for harness, £2, F. Long, Wetherby; second, £1, W. Clarke, Thirsk; third, 10s., T. Smithson, Ripon. Brood mare for the road, £2, W. Ingham, Ripon; second, £1, W. Garnett, Ripon; third, 10s., J. Burrill, Ripon. Brood mare for the farm, £2, G. Linton, Bedale; second, £1, C. Nicholson, Ripon; third, 10s., M. Tomlinson, Wetherby. Pair of horses for farm purposes, £2, J. Dalton, Ripon; se-

cond, £1, A. Somerville, Ripon. Hunting gelding or mare of any age, silver cup or £10, E. H. Flotmanby, York; £5, B. Nicholson, Leeds. Young gentleman's hunter, £3, W. T. Garnett, Ripon; second, £2, J. Burrill. Roadster, gelding, or mare, £5, F. P. Newton, Malton; second, £1, R. Barker, Malton; highly commended, W. H. Gaunt, York. Pony, not exceeding 14 hands, £1, W. H. Gaunt; second, 10s., C. J. Garnett. Pony, not exceeding 12 hands, £1 T. B. Maynard, Marton-le-Moor; second, 10s., M. Imeson, Masham. Three-year-old colt for the field, £1 10s., R. Green, Bedale; second, 10s., R. Green. Three-year-old filly for the field, £1 10s., W. Clarke, Thirsk; second, 10s., R. Manfield, Thirsk. Three-year-old colt or filly for harness, £1 10s., H. Wells, Kirklington; second, 10s., T. Scott, Broom Close. Three-year-old colt or filly for the road, £1 10s., E. Shepherd, Bedale; second, 10s., C. Knowlson, Thirsk. Three-year-old colt or filly for the farm, £1 10s., C. and W. Kendall, Azerley; second, 10s., A. Harris, Ripon. Three-year-old colt for the field, £1 10s., R. Atkinson, Northallerton; second, 10s., R. Wells, Thirsk. Two-year-old filly for the field, £1, J. Dalton, Ripon; second, 10s., J. Burton, Thirsk. Two-year-old colt or filly for harness, £1, L. Manfield, Thirsk; second, 10s., L. Manfield. Two-year-old colt or filly for the road, £1, W. Wardman, Kirby Overblow; second, 10s., W. Ingham, Ripon. Two-year-old colt or filly for the farm, £1, G. Mangles, Givendale; second, 10s., G. Mangles. Yearling colt for the field, £1, W. W. Gatliff, Littlethorpe Grange; second, 10s., H. Milner, Harrogate. Yearling filly for the field, £1, R. Pinkney, Northallerton; second, 10s., J. Daniel, Skelton. Yearling colt or filly for harness, £1, F. Long, Wetherby; second, 10s., J. Wells, Ripon; highly commended, G. Mangles. Yearling colt or filly for the road, £1, F. Long; second, 10s., C. Knowlson, Thirsk. Yearling colt or filly for the farm, £1, G. Mangles; second, 10s., R. Walker, Boroughbridge.

**SPECIAL PRIZE.**—Two-year-old colt or filly, by Yorkshire Grey, silver cup, value £5 5s., R. M. Bowman, Ripon.

#### SHEEP.

**LEICESTER OR LONG-WOOLS.**—Ram of any age, £2, J. Simpson, Spofforth Park; second, £10s., T. H. Hutchinson, Manor House, Catterick; third, J. Simpson; highly commended, T. H. Hutchinson; commended, J. Heugh, Mudd Fields, Bedale. Shearling ram, £2, T. H. Hutchinson; second,

£1, T. H. Hutchinson; third, 10s., T. H. Hutchinson. Pen of five ewes, £2, T. H. Hutchinson; second, £1, J. Simpson; third, 10s., J. Heugh. Pen of five shearing gimmers, £1, T. H. Hutchinson; second, 10s., T. H. Hutchinson; third, 5s., J. Simpson. Pen of five lambs, 10s., T. H. Hutchinson; second, 5s., R. E. Collinson, Ripon.

**SHEEP OF ANY OTHER BREED, OR A CROSS.**—Scotch ram, of any age, £1, J. Stubbs, West Summersides, Masham. Pen of five Scotch ewes, £1, J. Walker, Qilshaw, Grewelthorpe.

#### PIGS.

Boar of any age, of the large breed, £2, J. Dyson, Leeds. Sow of any age, of the large breed, £2, J. Dyson. Boar of any age, of the middle breed, £2, J. Dyson; second, £1, J. Dyson. Sow of any age, of the middle breed, £2, J. Dyson; second, £1, J. Greaves, Clothierholme; commended, W. F. Stephenson, Bishopton Close, Ripon. Boar of any age, of the small breed, £2, G. Mangles; second, £1, J. Dyson; highly commended, G. Mangles. Sow of any age, of the small breed, £2, J. Dyson; second, £1, G. Mangles; commended, G. Mangles.

#### IMPLEMENTS.

Myers and Sons, Sand Hutton, £2, for portable engine and thrashing machine, 10s., for coulter clover seed drill; G. Malhouse, Ripon, 10s., for assortment; Wm. Mattison, Leeming Bar, Bedale, £1, for one-horse reaper; H. Green, £1, for assortment; J. Ingram, Ripon, 10s., for assortment; W. Waide, Leeds, 10s., for churns; H. and G. Kearsley, Ripon, £1 or medal, for grass mower, £1 or medal, for chaff machine for power, and 16s., for thirteen-row patent chain drill; J. Speace, Ripon, 10s., for assortment; R. Nicholson, 10s., for improved lawn mowing, rolling, collecting, and self-acting delivering machine; J. Wood, South Stanley, £1, for assortment; H. Bushell, for Samuelson and Co., Skeldergate, York, £1, for assortment; J. Todd, Ripon, £1, for assortment; S. T. Stephenson, Stockton-on-Tees and Middlesbro', £2 or medal, for assortment, and 10s. for lime, gravel, and guano screens; W. Smith, Foston, £1, for fourteen-feet self-feeding sheep-rack; E. Sherwood, Bedale, 10s., for one-horse reaping machine; R. Cuthbert and Co., Leeming, 10s., for combined plough and digger; S. Croft, Ripon, £2 or medal, for assortment.

## THE HAVRE INTERNATIONAL EXHIBITION.

Not merely for the sake of the Exhibition now being held here, but for its own, for the objects of interest in all surrounding it, and for its nearness to districts celebrated at once for their fine old towns, rich in historical associations, grand old cathedrals and quaint buildings, and for much that is directly interesting to the practical farmer, the town of Havre is well worthy of a visit by those of our readers who can afford the time to make it. It is easily reached from the metropolis: you leave by the express from Waterloo at nine in the evening, and by means of one of the fine steamers of the South Western Railway, which leaves Southampton immediately after the train arrives from London, you may be amongst the quaint streets, strolling on the fine pier or promenade, or climbing the hill which forms the fine background of the city, in the early forenoon of the next day. Nor are the expenses of the journey likely to deter many; the fare per return ticket is very moderate, and for a few shillings more the journey to Paris and back may be added; and the expense of living in Havre is by no means great.

The title of the Exhibition, the "International Maritime," does not convey what are really the objects to be seen. Originally intended, doubtless, to comprise exhibits only connected with maritime matters, it has extended its objects, and now comprises a great number of objects generally interesting, and specially so to many of

our readers, of which more anon. The Exhibition is situated on a vacant space of ground in the Boulevard of Francis I., and the main or grand entrance, superior in point of design, and infinitely so in point of execution, to the grand entrance of the Paris Exhibition of last year, is within a few minutes' walk of the Hotel de Ville, a very handsome building, and faced by gardens very beautifully laid-out. The plan of the Exhibition—admission to which is one franc, after six o'clock half-a-franc—is very simple. It consists of a quadrangular space, surrounded with a continuous gallery or series of arcades, which contain the objects exhibited; outside of which, towards the quadrangle, eaved or verandahed galleries are placed, these being occupied either by shops for the sale of various articles, or by cafés, restaurants, and other places of entertainment. The quadrangle interior is laid-out very prettily with a series of garden-plots, which contain very beautiful collections of roses and pines. There are also spaces for various erections—as conservatories, kiosks, collections of building materials, machines, and last, not least, a huge aquarium for marine fishes and animals, which is really very interesting and suggestive. Altogether the whole exhibition reminds one very much of the grand one held in Paris last year, and in some respects it is superior. We have said that it is of a much more comprehensive character than was originally con-

templated, or as its special title would indicate; as for example group first—navigation, which embraces twenty-three classes, as sailing-vessels, their fittings and stores; steam-ships, their construction and machinery—would take in all the objects of a strictly maritime exhibition; but to this group are added others, as for example group second, merchandise and trade products; group third, fisheries; group fourth, fish-culture; and group fifth, supplementary or miscellaneous.

It is obviously with group second with which our readers are concerned, and with certain classes of it, as the classes taking up cereals, flour, seeds, and manures, and agricultural machinery and implements. It is to the last of these that we shall in the first place direct the attention of our readers.

The collection of agricultural implements and machines does not comprise a numerous list of objects, but many of them are good and several worthy of special notice. We shall economize time and space if we go through the various departments in regular order. Near to the circle or hall, and which, by the way, is well worth inspecting as a specimen of elegant decoration, obtained at a small expense, is a shed or annexe, containing a number of agricultural machines and implements, chiefly of foreign make, although a few of our own makers are represented by French agents. There are here several corn-cleaning machines, of which a brief notice will be useful. The first of those we meet with on entering is the one invented and made by Lhuillier, at Dijon. This consists of a rotatory cylinder of wires of different gauge, set at an angle, or inclined; this is supported at the upper and lower extremities by uprights, which are joined at the lower end to the framing of the machine; so that the cylinder is capable of being moved to and fro in the direction of its length, this motion being given to it by means of a connecting-rod worked by a small crank on the main axle or shaft. This vibrating motion is rapid, but extends only through a small space. In addition to this longitudinal motion, the cylinder has a rotatory motion given to it by means of a driving-belt passing over a pulley at the upper extremity of its shaft, this being passed over a pulley on the main driving axle of the machine. The double-motion thus given to the cylinder—a longitudinal and quick vibrating one, in the direction of its length, and a slow circular motion—keeps the grain passing through it in a state of continual movement, during which it is also subjected to a blast of air from a pair of faners. To prevent the substances sticking in the meshes of the wire of which the cylinder is composed, a hammer is provided, which is made to strike the outside at certain intervals.

The corn-dressing apparatus of M. Josse (at Ormeson, canton de Boissy-Saint-Leger, Seine-et-Oise) is distinguished by its simplicity, there being a marked absence of all complicated parts or movements apt to get out of order. In its simplest form, the apparatus consists of a triangular box, the bottom of which is made of wire; the sides, of wood some three inches deep. This is supported by spring uprights fixed at their lower end to a framework, in such a way that by moving the box to and fro a vibrating movement is given to the grain passing over its wired surface. The box is inclined from the upper or broad end to its lower or narrow end or apex. The lower framework carries an upright, which supports the hopper in which the grain to be cleaned is placed, and the grain is delivered into a small vibrating sieve at the small end. The main peculiarity of the apparatus here described lies however in the application of certain shaped blocks of wood or of pieces, forming when placed upon the bottom of the moveable or vibrating box a series of passages, along which the grain passes, and against which the grain is forced or driven by the vibrat-

ing action of the screen, in such a way that all extraneous matter is separated from it and passed away while the cleaned grain is kept separated. In applying the principle to a dressing-machine calculated to do a large amount of work, the blocks are placed in the wire screen, and a motion from side to side is given by means of connecting rods and cranks worked from the main axle, to which the motion of the prime mover is given in the usual way. The following rough diagram will explain the mode of placing the blocks upon the moveable screen:

The grain in its passage down and along the parts *a a* and *b b* is driven against the projecting parts and sides of the blocks *c c* and rapidly separated from all extraneous matter. It is only right to say that the work done by this apparatus seems very good, and that a very large number of apparatus has been sold. The same remark applies to the form of corn-dressing machine exhibited close to that of M. Josse, under the name of the "American machine," and which is well known to our readers as that of Child's. It is made in France by Messrs. H. and G. Rose frères, engineers at Poissy (Seine-et-Oise), and who have, we believe, done a large business in connection with it. As our readers are aware, the main feature of this machine is the employment of a double-blast, or rather of two currents of air—one of which is on the plenum or full, the other on the vacuum or exhaust. The exhaust serves to keep the grain suspended, and is so regulated that all the light grains are passed away, while the heavy or best grain are retained by themselves. This regulation of the force of the exhaust is secured by means of a valve, which is operated upon by a lever and weight. Next to the American machine is the decortiating apparatus, made by the celebrated engineers, J. F. Cail et Cie. and Barrabe, Quai de Grenille, Paris. This consists of two metal cams, provided with projecting ribs on their outer and inner surfaces; one cam working within the other, the latter being fixed. A very neat application of Robertson's frictional gearing is applied to this machine, to work the revolving cam, in place of the bevil gearing usually employed.

There are several collections of mill-stones of the class for which the French mills are so famous, and a few examples of mill construction. In this department there is exhibited by C. Touaillon fils, Boulevard Sebastopol, Paris, a small apparatus for dressing mill-stones. Our readers are aware that a good deal of attention has been lately directed to this class of mechanism, notably through the remarkable success—pecuniary if not mechanically—which has been met by Golay's patent, which was exhibited for the first time publicly at the Paris Exhibition of last year. In Golay's patent machine the cutting-tool is a hard Brazilian diamond, and is

actuated by machinery of a very ingenious character. In M. Tonnillon's apparatus, now to be described, the cutting-tool is a hard-faced steel chisel (*a*), about one-inch broad. This is worked hammer-fashion, being fixed vertically (*a*) in the slotted end of a horizontal lever (*b*); this lever

passes through and is fixed by a screw in a slot (*c*) at the upper end of a stud which is carried by a horizontal lever

(*d*), supported and carried by the frame or carriage of the machine; the hammer-chisel (*a*) is worked by hand, the hand grasping the lever (*b*) near the chisel (*a*), and lifting it up and down, inflicting through the medium of its sharp edge a "crack" or line on the face of the stone. The carriage of the apparatus is placed upon the millstone in such a position as that the face of it will be parallel to the line or crack to be dressed or made in the millstone face; by means of a simple arrangement of screw, the change of position of the chisel as it cuts the "crack" is very easily made.

Golay's millstone dressing-machine to which we have above alluded, although not exhibited in the same place as the apparatus just described, it being in the inner gallery in the machinery-in-motion department, we may as well describe it here. This machine was first exhibited in Paris, in the Exposition of last year, and it has since attracted a large amount of attention in this country from the very large sums which have been obtained for licences for working it. These sums have been so large that the purchasers of the patent for this country have made a sum considerably exceeding one hundred thousand, some of the licences sold having got up to the large figure of £21,000. Our readers will be pleased, therefore, to receive here a description of a machine which has taken so fortunate a pecuniary position. The machine is of small size, neat and compact in arrangement, and easily adjusted to the millstone which it is employed to dress. Unlike the form of apparatus last described, the whole work is done by mechanism, no manual labour being required. The cuts or cracks or lines made in the face of the mill-stone are cut by means of a diamond, fixed in the face of a small disc, to which a rapid motion of rotation is given. The mode by which the diamond is fixed in the disc is very ingenious. The disc is in reality made up of two discs, which are screwed on to the axle, and bear up against a shoulder in the same. On the face of the discs small recesses are cut at intervals: these are cut from the circumference, a short way towards the centre, so that when the two discs are placed together, cells are formed opening to the periphery of the disc. The diamond is placed in one of the cells, and when the discs are screwed tightly up, is held fast, a part or point projecting from the periphery. The means by which rotation is given to the disc with its cutting diamond point, and by which it is moved along so as to cut the proper line required, may now be described. A frame is connected with a central socket pillar, which passes into the end of the axle of the mill-stone to be dressed. From this central pillar

three arms radiate, provided at their extremities with screws, which pass through apertures, and press up their larger ends upon the face of small plates of iron, which in turn rest upon the mill-stone. By raising or lowering the screws, the frame of the apparatus is levelled [as desired]. The carriage which carries the rotary disc or tool-holder, slides out and in towards or from the central pillar, and consequently over the mill-stone surface, in a dove-tailed guide, passing along a horizontal arm, which is connected with the framing, and which arm is adjusted by a bolt which is passed into a curved slot in the support. By this arrangement the arm can be moved in an arc of a circle at will, and the tool-carrier moved out and in towards the circumference as desired. The upper part of the central socket or pillar is formed into a socket or "step," which carries a small vertical shaft, to which rotation is given by means of a small pulley, worked by the prime mover. The vertical shaft carries another pulley, the belt or end of which passes over a pulley at the end of a bracket, which is carried by the central pillar, and which is socketed in the same, so as to be able freely to move. The proper tension is kept on the cord or belt by means of a counterpoise placed at the end of the socket or jointed bracket. From the pulley at the end of the bracket a cord or belt passes to the axle of the rotatory disc or tool holder and round a pulley fixed thereon. The carriage which carries the tool-holder is capable of having the necessary motion along the slide or lever by means of a bell-crank lever. While the tool-holder is revolving with great rapidity, the diamond on its face cutting the line on the mill-stone by means of the bell-crank lever, the carriage is moved along the slide so as to enable the tool to operate in the direction of the line of cut required. When the line is finished the tool is then moved so as to draw a line parallel to the first: this is effected by making the tool-holder move in a slide, which is carried by the horizontal arm, this slide being at right angles to the direction of the slide passing from the centre to the circumference. To complete the parallelism of the lines, the support carrying the arm is moved in the curved slot, a short distance, and fixed by the screw. The machine effects its work in a very complete manner, not only doing the grooves or cracks very sharply and with precision, but a large saving of time is effected. Thus taking the time of dressing a millstone in the ordinary way by hand at nine hours, this machine can do the work completely in two hours or in two hours and a-half, which is equivalent to a large saving in the working year.

E. Goudouin, of Boulevard Poissonnière, Paris, exhibited specimens of his wire-work fences, and an exceedingly neat hen-house of galvanised iron-wire. M. Goudouin has supplied the Zoological Gardens in Paris and those of the Society of Acclimatization at the Bois de Boulogne with the various iron enclosures. Some of the wire-workers might with advantage take a lesson or two in the designing of poultry-houses and sheds, aviaries, &c.; some of the designs met with abroad, for these, being exceedingly elegant, and must have been designed by special artists. The same also may be said as to erections in wood suited for gardens, of which there are several specimens in the park of the Exhibition, amongst which we may specially notice the "kiosk" made by M. Bouvière, of Harfleur; not only for the elegance of the general design, but for the beauty of the cut wood and fret-work in which it abounds, this structure is worthy of the special notice of the visitor. It is occupied as a confectioner's stall; but if it had a place in the grounds of some of our rich men, we can fancy him a very much envied man for having a structure so beautiful.

There are a few machines used in the preparation of

flax, sent from the North of France, where that plant is grown to a large extent, and made into fabrics. M. Pareyelt, of Bergues (near Dunkirk), sends a very simple yet efficient form of flax-breaker. This resembles very closely the paddles of a steamer; but the floats, in place of being horizontal and between two rings of iron, are placed so as to project from the face of a single ring, and to present a flat striking edge to the flax which is held to their action. The central shaft carries two rings thus provided with beaters, one ring at each end, a space being left between them.

Edmund Garmeson, Quai de Billy, Paris, has a pretty extensive collection of agricultural machines and implements in this annexe, the majority of them being of foreign design and make, although he has some of English makers, for many of whom M. Garmeson is agent for France. The collection at this point will afford the visitor from England a fair opportunity to contrast the machines and implements of his own country with those of France, and the points of contrast will, we feel assured, be striking enough. On this point we do not deem it necessary to repeat what we have already taken the opportunity to say in the first papers which we have had the privilege to give in this Journal, under the title of "Novelties at the Paris Exhibition of 1867," and to which we therefore refer the reader who cares to know what is there said upon the point now being referred to. A few practical exemplifications of it may be met with in the annexe now being dissected, as for example one in the corn drill of M. Jacquet Rovillard, Arras. This machine has three carrying wheels, one of them being in front between the shafts which project before the body of the apparatus; the axle of this front wheel carries two eccentrics, which move connecting rods carried back to the corn-delivery part, and which work its mechanism. The delivery of the corn is regulated by a set screw to each coulter part—a very tedious method, and one open to extreme irregularity in the adjustment of the whole.

The French, as our readers are aware, have paid much attention of late to apparatus designed to dry and preserve grain. Some of those lately introduced are very complicated, at least of gigantic dimensions, and of course costly. A very compact arrangement is met with in this annexe, the invention of M. Ballarieux, 52, Rue des Prés, Havre. It consists of a cylindrical receptacle, the air in the interior of which is heated by a central stove or fire-place, the feeding part of which projects from the lower and central part of the cylinder. The top of the cylinder is provided with sides and ends, which forms a species of hopper, the bottom of which is the heated and upper portion of the cylinder. The grain to be dried is in the first instance placed in this hopper, so as to give it a preliminary drying. When sufficiently long in this, it is passed out by a shoot into baskets, and the contents of these are next passed into a shoot or hopper at the end of the machine. This hopper conducts the grain to a helical screw placed in the interior of the cylinder, the revolution of which is effected by means of a driving pulley on the main shaft, worked by wind or power. The shaft of this screw is hollow and perforated with holes, and a stream of hot air is forced through it so as to fill the interior, and act upon the grain. The heated air is obtained by forcing, by means of a small fan at the other end of the machine, a current of air through the small furnace, which, as above described, is placed underneath the main cylinder; the tube which carries this heated air being terminated with a nozzle projecting into the open end of the hollow axle of the screw. As long as the screw is made to rotate in one direction, the grain in its interior is kept in, it being tossed to and fro and subjected to the hot air; but when the screw is

turned the reverse way, the grain is passed out by a shoot at the end.

Glancing at a collection of cider-presses (Normandy is celebrated for its cider) and at a compact corn-dressing machine, flour-mill and flour-dressing apparatus combined, we pass on to the machinery gallery in the main range, and take up the notice of such objects which we there meet with. The agricultural machines here met with are principally straw-cutters, root-cutters, thrashing-machines, and portable engines. Of these latter, the three noteworthy are (1) the engine of MM. Weyher, Lorean, and Co., of Paris; (2) that of MM. Albaret and Co.; and (3) of M. Gerard. We notice that of Weyher and Co. first, not because of any excellence it possesses, but rather as it affords a somewhat remarkable contrast to the engines of this class of our makers. The first point it presents is the heaviness, and shall we say clumsiness, of the whole; as regards the mere weight, we should say it is not far off being double that of engines of similar power made here. The working arrangements are very defective; for example, to get at the starting-handle the engineer must either climb up by one of the wheels or have something on which to stand to raise him up to its level, so high above is it placed. The engine is secured to a heavy cast-iron bed-plate, resting on the boiler; none of the parts being covered by the boiler, as with us. The boiler itself is on the Cornish principle, not well proportioned; it extends to the end of the engine, and the smoke and heated air are brought back to a smoke-box near the fire-door, by return flues or tubes, after the fashion of Carrett's portable engine, of Leeds. The boiler is provided with what appears to be a steam dome, but is in reality a water-heater, the exhaust-steam pipe passing through it. The engine of MM. Albaret and Co. is a much lighter and better proportioned machine, although in these respects it does not come up to our standard of efficiency. The mechanism by which any required degree of expansive working of steam is obtained may be noticed here. The eccentric rod is jointed at its extremity to the upper end of a curved link, the lower of which is well jointed to a stud fixed to the side of the boiler. This curved link carries a small sliding-block, to which is jointed the end of a lever which is carried forward to the valve-check and works the valve. This valve-rod is provided with a slotted part near the curved link, before named, and through this slot the end of a lever projects; this lever is provided with a screw and hand-wheel near its curved end, at which point it is jointed to a stud fixed to the side of the boiler. By turning the hand-wheel the screw is reversed and lowered, and with it the slotted part of the valve-lever; this causes the sliding-block to rise or fall upon the curved link, to the end of which the eccentric rod is jointed. By this arrangement the throw of the valve-rod is altered as desired. M. Gerard, Vierzon (Cher), exhibits a portable engine of which the design and workmanship afford a good contrast to the one of MM. Weyher and Co. alluded to above. M. Gerard has introduced a modification of the ordinary governor, which may be described here. The lower part of the vertical lever which carries the jointed levers and balls is provided with a third ball, of much larger dimensions and heavier weight than the ordinary balls. Immediately below this counter-weight is placed the stud which carries the end of the lever which communicates with the throttle valve. The action of the heavy or third ball is direct upon the ordinary pendulum balls of the governor, preventing them from flying too rapidly out, and thus stopping or slackening the speed of the engine. But in order to change at will the speed of the engine, M. Gerard adds a fourth ball to the apparatus, this being placed upon the lever which actuates the throttle valve, and it is made capable of sliding to-and-fro

upon this, so as to approach or recede from the centre of the lever and nearer to or further from the vertical lever which carries the governor. When this fourth ball is brought near the centre lever the engine is made to quicken its speed, and by taking out the ball further from the centre the engine is slackened in speed. M. Gerard exhibits a straw-cutter, in which there is an ingenious arrangement for altering the length of cut, and for regulating the delivery of the straw to the cutting-knives. The shaft of the fly-wheel, to which the knives are fixed, is parallel to the feed-box, and carries at the extremity, farthest from the fly-wheel, an elliptical-shaped cam, which has upon its surface paths or faces of varying diameter. Working in contact with one of the faces is a small force-wheel fixed to the end of a lever, and capable of turning upon a small stud at its end. This lever is jointed at its other end to a stud fixed to the side of the machine, and forms half of a bell-crank lever, the other half of which stands vertically; the extremity of this is provided with a lever which is carried forward and terminated with a pawl which takes into a ratchet-wheel keyed on to the upper feed-roller. The revolution of the elliptical cam, with its varying path, gives a to-and-fro motion of the bell-crank lever, which, by means of the pawl at its furthest extremity, moves the ratchet-wheel of the feed-roller a certain portion of its revolution, and thus delivers a certain length of material to be cut. By changing the position of the friction-wheel at the end of the bell-crank lever near the cam, so as to work upon one or other of the paths of the cam, certain degrees of change of throw of the bell-crank lever are obtained, and by consequence different lengths of cut. For all practical purposes a variety of lengths of cut are not required, two being found quite sufficient, and we know of no arrangement so simple and efficient by which these two lengths can be obtained as that recently introduced by Richmond and Chandler, a specimen of which we regretted not seeing at the Exhibition.

Wilson & Co., of Vauxhall Iron Works, London, exhibit several forms of donkey steam-pumps for supplying boilers and pumping water. Messrs. Wilson have introduced some improvements in the arrangement of these pumps, which are on Brown's patent, which we fully described last year. Our readers may recollect that the connecting rod in Brown's pumps was bent; this arrangement had the tendency to throw an indirect strain upon the rod and the crank-pin in the face of the flywheel. Messrs. Wilson obviate this, and secure other advantages by their very simple, and valuable because simple, arrangement. To the pump-ram a stud is cast, projecting at right angles from it, and working in a vertical guide. The stud is brought sufficiently forward to admit of the lower end of the connecting-rod to be jointed to it, in a line with the crank-pin on the flywheel above, thus securing a direct line of action. By simply bringing the flywheel shaft, and the eccentric cam which works the steam-valve, outside the steam-crank or casing, every facility for oiling is obtained.

M. Mezeline, of Havre, exhibits a steam-pump, on the principle of Worthington's American pump, the distinguishing feature of which is the absence of cranks, fly-wheel, and shafts. These are dispensed with by simply placing a pair of steam-cylinders at one end of the frame horizontally, and parallel to one another, and the piston-rods of which are connected directly with the rams of two pumps placed at the other end of the frame. The valves of the cylinder are worked by levers from the piston-rod of the other cylinder. M. Bowden, of Paris, exhibits his steam-pump, in which the steam-cylinder, and the pump, or ram, are placed at each end of the frame, and both horizontally; the ram is worked from a slotted link placed between the cylinder and the ram, the

piston-rod being attached to one piece of the link, or ram-plunger, and the other side the flywheel-shaft is put to a double crank, and connected at each end to the sides of a block which slides in one link. As the crank revolves the block rises and falls in the link, and the parallelism of the piston-rod and pump-plunger are preserved.

Messrs. Gwynne, of the Hammersmith Works, London, exhibit their steam-engine and centrifugal-pump combined. The whole is so well arranged, and the parts constructed with such nicety, that the engine can run at the rate of no fewer than nine hundred revolutions per minute, without any shaking or vibration of the foundation or base-plate. Working at 414 revolutions per minute, it will throw 500 gallons per minute to a height of 30 feet. The whole occupies but a very small space—about 3 feet 5 inches by 3 feet. Steel is employed, to a large extent, in its construction: as, for example, the piston and piston-rod (which are cast in one piece), the main shaft, the crank disc, or face-plate, and the crank-pin, are also in one piece of Bessemer steel. Messrs. L. Neat and L. Dumsut, of Paris, exhibit specimens of their centrifugal pumps, one of which is employed in pumping up the water from the sea for the supply of the gigantic marine aquarium in the park, which by the way is a special object of attraction to the visitors, and worthily so. An hour or two may be spent, both pleasantly and instructively, in examining the various departments of this aquarium. Contrasting with the compact centrifugal pumps, is the huge chain-bucket pump or lifter, which is exhibited in the park, with portable engine attached, by M. Saint Romas, of Paris. For many situations this form of water-lifter may be used with advantage: it seems well made.

Closely connected with the question of water supply is that of appliances used in distributing it; as for example, water meters and pipes. An excellent form of water meter—probably the best yet introduced—is that invented by Mr. Worthington, of America. A meter on his principle is at work in the Exhibition. There are two cylinders employed in the meter of the same capacity, laid side by side and horizontally; the valves of one cylinder being worked by means of connecting rods and links attached to the other cylinder, the motion of the cylinders being in the reverse direction, that is as one goes out the other is going in. The cylinders work with a very small pressure or head of water, as low as two ounces to the square inch, and they will register accurately with even the smallest escaping flow. As a rule water meters are not much to be depended upon for extreme accuracy of working; but the one under notice seems to fulfil all the requisite conditions in a very satisfactory manner. As regards the distributing pipes for water supply, a very interesting stand is that which contains numerous specimens of the tin-lined lead pipes made upon Hamon's system. Our readers are all well acquainted with the evils arising from the action of certain waters upon lead, creating a substance which, if partaken of regularly, brings about many complaints of a peculiarly distressing character. This has been well-established by many eminent medical men, who have had their attention directed to the matter through the occurrence of accidents—if we may so term them—arising through the use of water passing through lead pipes. To obviate the dangers arising from the use of leaden pipes, many attempts have been made to introduce another material—or to use in conjunction with the lead pipes another material not acted upon by the water—as tin, which was coated upon the lead. But in practice the coating was never efficiently done; while the use of pure tin pipes was precluded from their great expense as compared with lead. M. Hamon has overcome all the difficulties attendant upon the use of tin in conjunction with lead by a very

ingenious process, by which a very thin but perfectly solid and homogeneous tin pipe is incased in, or enfolded by, a lead pipe. The two pipes are produced simultaneously by driving, by enormous hydraulic pressure, the lead and tin over two concentric rollers or matrices; and the two metals are in complete coherence, and the thickness throughout the whole length of pipes in both materials of absolutely uniform thickness. One great advantage in the use of these tin-cased pipes for water-closet and scullery-sink purposes is that refuse matter does not adhere to the interior tin pipe. Those of our readers who are practically acquainted with the evils arising from the rapidity with which the lead pipes in the above appliances get coated with foul matter, will be able to appreciate this advantage of the tin-cased lead pipes which we have now described.

We shall conclude our notice of the Havre Exhibition by describing a few odds and ends met with in the galleries. And first as to a cow-milking apparatus, the invention of M. Liverbardon, Rue de Provence, Paris. We cannot say that we are an ardent believer in the milking of cows by mechanical means, certainly not in such as aim at effecting it by such means of a complicated character. The majority of farmers believe, and they have at least a great deal to say on their side of the question, that milking the cow, like some other operations in practical farming, is best done by hand, and that all complicated apparatus to operate this should be avoided. Certainly the apparatus now before us has not this charge of complication of parts to go against it. Nothing can indeed be more simple; it consists of a small silver tube, which is simply inserted in the orifice of the teat, and which serves as a tube by which the milk vessels completely empty themselves. The apparatus has been tried by several eminent Continental agriculturists, who speak highly of the completeness of its action and the ease with which it can be used; and whether the fact will have any weight with our readers or not, which will depend upon the views they hold of the prize system, the appliance has had a prize awarded to it at the agricultural show held at Amiens last year. Before inserting the tube, the teat should be filled or swollen out with milk brought down by hand; the tube is then inserted gently, giving it on its entrance a slight turning motion which will facilitate its passage into the orifice of the teat.

M. Masson, of 10, Avenue du Cimetière du Nord, Paris, exhibits an apparatus by which the quantity of corn used per day in stables is measured with extreme accuracy. For large establish-

ments, where waste if not speculation goes on, in many cases to a large extent, we believe such an apparatus would soon pay itself. The corn is freed from the apparatus by withdrawing a flap acted on by a handle placed under the dials or indicators, falling into a receptacle placed beneath, from which it is taken as required. The corn is supplied from a room above, under lock and key, and all supplies required must pass through the apparatus and the quantity recorded.

There are several forms of lubrication in the Exhibition, one or two of which we shall notice briefly here. The first is that made by De La Coud, Rue Saint Lazare, Paris, and which consists of a ball of thick glass, provided with a brass collar at its opening; this is embraced by a brass cover, which carries a small projecting tube a short distance on either side of the cover. This is closed at the end which remains in the bulb of glass when the cover is put on; but a small aperture is made in the end, as well as one or two small holes made in the side of the tube below the end. The end, with its perforation, is formed like a cup, so that it can be taken off when the tube requires cleaning. The glass ball being filled with oil, and the cup and tube put on, the whole is reversed, the lower end of the tube passing down the oil-hole in the journal or shaft-pedestal, and allowed to rest upon the shaft or journal. As this revolves, the oil is drawn out of the bulb drop by drop, and is replaced by air which passes up the tube, and through the holes in it, into the upper part of the glass. The more quickly the shaft revolves the more rapidly is the oil withdrawn. A method of lubricating the working-parts of steam-engine cylinders recently introduced is that of mixing the steam supplied to the cylinder with fatty matter. A mode of doing this, as patented by Morton and Wilson, and sold by A. Robinson and Co., of Canning Dock, Liverpool, is exhibited in the gallery. It is an apparatus of a very simple character, being merely a receptacle which is to contain the fatty matter, as oil or of soap melted, and which is placed upon the steam-pipe leading to the cylinder. By turning the middle of the indicator the steam is admitted to the interior of the receptacle, and passing to its upper part, is there condensed into water; this being heavier than the lubricating material, descends to the bottom, and displaces it; the lubricating material, after a short interval, begins to descend, drop by drop, into the steam-pipe, where it mixes with the steam, and is carried forward to the various working-parts. The greasy steam thus formed acts as an admirable lubricant of all the parts.

## BRUSSELS INTERNATIONAL AGRICULTURAL EXHIBITION.

The exhibition of the Agricultural Society of the Province of Brabant, held in Brussels last week, was formally opened on Saturday, the 20th June, by the King and Queen in person, under an almost tropical sun, with all the pomp of military display so loved on the continent, amidst a crowd of Belgian nobility. The exhibition was international as far as implements and machinery were concerned, but confined to the province of Brabant as regards animals; while without the presence of English manufacturers the show of implements and machinery would have been poor; and of course our exhibitors were very successful in the competitive trials.

Still the show of machinery and implements was very large, numbering nearly 1,000 machines in all. England was represented by 17 exhibitors, with about 120 different articles of their manufacture. Amongst the English exhibitors were the following: J. and F. Howard, Ransomes and Sims, Aveling and Porter, Ruston and Proctor, Marshall, Sons, and Co., E. B. and F. Turner, Richmond and Chandler, Horneby and Sons,

and Woods and Cockledge. The implements were all placed in rotation—that is, the ploughs of all exhibitors were near the entrance; afterwards harrows, scarifiers, rollers, drills, reapers; and lastly steam-engines and thrashing-machines—an arrangement which suited the juries very well, but entailed a vast amount of labour to the staff of any exhibitor who had more than one machine. The juries were composed of well known men, and amongst them we may mention James Howard, of Bedford, for drills; Thomas Ritson, of the Luxembourg Railway, for steam-engines; Messrs. Albaret, the celebrated French implement manufacturers, for thrashing machines; Professor Ran, of Carlsruhe, for ploughs; and the juries gave each machine a fair and patient trial, devoting nearly a week to their investigation. The principal prizes to English firms were awarded as follows: Steam-engines, first prize Ransomes and Sims; second, Ruston and Proctor; third, Marshall, Sons, and Co. Steam thrashing-machines, first prize, Ransomes and Sims; third, Ruston and Proctor, also a third prize for

small thrashing-machines to Marshall, Sons, and Co., and E. B. and F. Turner. Traction-engines, first prize, Aveling and Porter. Ploughs, first prize, J. and F. Howard; another first, Ransomes and Sims; and "Prize of perfection" for turn-wrest plough, Ransomes and Sims; prize for potato plough, J. and F. Howard. Haymakers, first prize, J. and F. Howard; horse-rakes, first prize, J. and F. Howard; second, Ransomes and Sims. Drills, first prize, general purpose drill, Smyth and Sons, Peasenhall. First prize manure drill, Smyth and Sons, Peasenhall. The prizes for chaff-cutters, bruising-mills, turnip-cutters, oat-bruisers, and horse-gears, were in most instances awarded to Richmond and Chandler, E. R. and F. Turner, Woods and Cockledge, and Bental.

The show of cattle was excellent, the large Brabant horses carrying off the principal prizes; the Shorthorn and Dutch cows also attracted a great deal of attention from cattle breeders; and there were some good Southdowns, Oxfordas, and cross-bred sheep. Mr. Charles Howard was requested to go on as a judge of Shorthorns, but was unable to act.

Many prizes were only awarded to new inventions or improvements. Medals, scattered in profusion, were of "vermilion" or silver gilt and bronze, handsome in appearance; one Eng-

lish exhibitor took home nearly a dozen of them. As is usual in continental shows, a lottery was established for the purpose of purchasing standard implements and machinery selected by a special committee, by which means a certain number of good implements and machines are certain to be left in the district. This Brussels lottery was particularly successful, and a placard "Acquis pour la lotterie" was found on a great many English implements and machines. We regret to say that some of the foremost British exhibitors ran their engines and thrashing machines on Sunday, though, as far as we could learn, to little purpose, no sales being effected. We commend this fact to the notice of the Lord's Day Observance Society. The President of the Brabant Agricultural Society, Mr. Leclercq, who organised the exhibition, received from the hands of the King the decoration of "Officer" of the order of Leopold, which is analogous to the French Legion of Honour. A banquet in honour of the jurors was held on the evening of the 22nd instant, when the healths of the King and Queen, Prosperity to the Society, Health of the President, Thanks to the Home and Foreign Exhibitors, were received with great enthusiasm, the hips and hurrahs of the English exhibitors being particularly noticeable. The speeches were plentiful, and good.

## THE SUPPLY OF FRESH MEAT.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—As there is much misconception about the proportion of Home and Foreign Supplies of Meat, I have prepared a short calculation on the subject, which is founded entirely on Mr. Dudley Baxter's estimate of the quantity of cattle and sheep killed in this country. That estimate I consider a low one—it is his, not mine—but it shows how little we yet depend on the foreigner for our fresh meat. The number of foreign Cattle imported during the past eight years average 170,000; but, as I think they may increase, I have put up the numbers to 200,000. I don't suppose that the quantity of Sheep and Pigs will alter materially, and

have therefore taken the actual average of the past eight years' importations.

Mr. Dudley Baxter is the agent for the cattle importers and butchers, and leads the opposition against the Metropolitan Cattle Market Bill. In order to make the case of the poor worse than it is, in his pamphlet Pigs are ignored; but I have supplied that deficiency, and give my rough estimate to my brother-farmers for what it is worth.

I am, Sir, your obedient servant,

CLARE SPWELL READ.

House of Commons, 3rd July, 1868.

### PROPORTION OF HOME AND FOREIGN SUPPLY OF FRESH MEAT TO THIS COUNTRY.

	Number slaughtered Annually.	Proportion of Foreign to Home.	Weight per Carcase in lbs.	Number of lbs.	Proportion of Foreign to Home Supply in lbs.	Price per lb.	Value of Home and Foreign.	Proportion of Value of Foreign to Home.
<b>CATTLE</b> (INCLUDING CALVES)								
Home.....	2,500,000		580	1,400,000,000		7d.	£ 40,833,333 6 8

Total*.....	19,000,000	2,477,000,000	70,558,333 6 8	Total*.....	800,000	129,500,000	3,228,125

\* The Foreign is One-twenty-fourth of the NUMBERS, One-eightieth of the WEIGHT, and One-twenty-third of the VALUE of our Home Supplies.

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

**MONTHLY COUNCIL, Wednesday, July 1.—Present:** the Duke of Richmond, K.G., President, in the chair; the Earl of Powis, Lord Bridport, Lord Chesham, Lord Kesteven, Lord Portman, Lord Tredegar, Lord Vernon, Lord Walsingham, Sir Massey Lopes, Bart., M.P.; Sir A. K. Macdonald, Bart.; Sir T. Western, Bart.; Sir Watkin W. Wynan, Bart., M.P.; Mr. Amos, Mr. Barnett, Mr. Cantrell, Colonel Challoner, Mr. Brandreth Gibbs, Mr. Hornsby, Mr. Jonas, Colonel Kingscote, M.P., Mr. Milward, Mr. Pain, Mr. Randall, Mr. Ransome, Mr. Read, M.P.; Mr. Rigden, Mr. Sanday, Mr. Shuttleworth, Mr. Stone, Mr. Thompson, Mr. Torr, Mr. Turner, Mr. Webb, Mr. Wells, Mr. Jacob Wilson, Professor Simonds, and Dr. Voelcker.

The Duke of Sutherland, K.G., and Lord Kenlis were elected Governors of the Society.

The following members were elected:—

Agar, Thomas, Lower Hastings Street, Leicester  
 Agar, William, 5, Upper King Street, Leicester  
 Allen, John, Ashfield House, Knighton, Leicester  
 Angrove, Thomas Cooper, East Leake, Loughborough  
 Ardron, John, Queniborough Cottage, Leicester  
 Arkwright, Arthur W., Broughton Ashley, Lutterworth  
 Ashby, John W., Knaptoft, Husband's Bosworth, Rugby  
 Bantoch, Thomas, Merridale House, Wolverhampton  
 Bellairs, George Clarke, The Newark, Leicester  
 Boddington, Henry, Monton House, Eccles, Lancashire  
 Brewster, John, Stretton Mill, Penkridge, Staffordshire  
 Bryan, Thomas, Seaton Lodge, Uppingham  
 Bard, Thomas Augustus, Burcot, Wellington, Salop  
 Barley, John Henry, Leicester  
 Chapman, W. Henry, Humblestone, Leicester  
 Cheate, Thomas Farmer, Dosthill, Tamworth  
 Clark, J. W., 84, Belvoir Street, Leicester  
 Coleman, G. W., Great Glen, Leicester  
 Crawley, J. Rogers, Melchbourn, Higham Ferrers  
 Crawley, Lewis, Knightley House, Holbeach  
 Crickmore, Robert, Ingloss, Loddon, Norfolk  
 Crickmore, William, Seathing, Brooke, Norfolk  
 Croeland, James, Clumber Street, Nottingham  
 Day, Neville, Easton, Stamford  
 De Wend, W. Fenton, Croft Lodge, Leominster  
 Ellis, Alfred, Belgrave, Leicester  
 Fowler, Lawrence P., Little Bushey Farm, Bushey  
 Fyers, Colonel, W. A. C. B., United Service Club, S. W.  
 Gamble, Henry Thomas, 28, Lincoln Street, Leicester  
 Goddard, Joseph, Stoneygate, Leicester  
 Grealey, Sir Thomas, Bart., Cauldwell Hall, Burton-on-Trent  
 Harris, George Shirley, Leicester  
 Harris, John Dove, Knighton, Leicester  
 Harris, Samuel, Westcotes, Leicester  
 Hasley, Joseph Barber, Leicester  
 Heathley, James Henry, Engleton Hall, Penkridge  
 Henty, Robert, Rothley Temple, Loughborough  
 Hume, Charles T., Waterloo Terrace, Bridgnorth  
 Ingram, Thomas, Wigston Magna, Leicester  
 Leadbeater, John B., Thorpe Sachville, Melton Mowbray  
 Lott, John, 156, Victoria Park Road, Hackney, Middlesex  
 Lowe, Thomas Foster, South Croxton, Leicester  
 Macfarlan, Walter, Bretton Lodge, Wakefield  
 Moore, Henry, Calverton, Nottingham  
 Moore, John, Calverton, Nottingham  
 Murray, Gilbert, Elvaston Castle, Derby  
 Munn, E. B., Royston  
 Preston, Benjamin B., Leicester  
 Preston, William, Leicester  
 Pullen, Richard, Shackerley House, Albrighton, Salop  
 Quenby-Ashby, Rev. E., Quenby Hall, Leicester  
 Reeve, William Napier, Leicester

Richards, William, Belgrave, Leicester  
 Richardson, J. G. F., Houghton House, Knighton, Leicester  
 Rider, Thomas John, Kenwick, Shrewsbury  
 Roberts, Edward, Berden Hall, Bishops' Stortford  
 Rodgers, Herbert, Gilmorton, Lutterworth  
 St. John, Beauchamp Mowbray, Melchbourne, Higham Ferrers  
 Shaw, George, Leicester  
 Simpkin, Thomas Henton, Hoby, Leicester  
 Sing, Henry, Swancote, Bridgnorth, Salop  
 Sing, William, Newton, Bridgnorth, Salop  
 Smith, Henry, The Grove, Cropwell Butler, Bingham, Notts  
 Stark, W. P. W., Knaptoft Hall, Rugby  
 Strutt, Hon. Arthur, Duffield, Derby  
 Strutt, Hon. Frederick, Kingston, Derby  
 Suffield, Lord, Ganton Park, Norwich  
 Tailby, W. Ward, Skeffington Hall, Leicester  
 Taylor, John, Leicester  
 Towgood, Hamer, Little Shelford, Cambridgeshire  
 Towgood, Edward, jun., Sawston, Cambridge  
 Watt, William, jun., Leicester  
 Whitwell, John Jenkins, Silsworth Lodge, Crick, Rugby  
 Williams, Henry, Alma Farm, Truro, Cornwall  
 Wood, John, Fridmore, Nottingham  
 Wright, Thomas, Wanlip, Leicester  
 Wright, William, Shoby Priory, Melton Mowbray  
 Wynan, Richard, Crickett, Eilemsere, Salop.

**FINANCES.**—Major-General Lord Bridport, chairman, presented the report, from which it appeared that the secretary's receipts during the past month had been duly examined by the committee, and by Messrs. Quilter, Ball, and Co., the Society's accountants, and found correct. The balance in the hands of the bankers on the 30th June was £1,340 9s. 9d., and £2,000 remains on deposit. The quarterly statement of subscriptions and arrears to 30th June, and the quarterly cash account, were laid on the table.

**JOURNAL.**—Mr. Thompson, chairman, reported the recommendation of the committee, that, as the appointment of a new editor cannot be made for some months, the committee be authorised to make arrangements with Mr. Goodwin to continue his services, and prepare the matter for the February number of the *Journal*.

**PRIZE ESSAY.**—Mr. Thompson having announced the award of the judges, and the motto-paper having been opened by the President, the successful competitor for the prize of £30 in Class X., "Rise and Progress of the Leicester Sheep," was declared to be Mr. H. H. Dixon, of 10, Kensington-square, W.

**EDITORSHIP.**—The President read the following report:—

"The following letter from the secretary was read and considered by the committee:—

"My Lord Duke,—Having served the Society for nine years, and those perhaps the best of my life, I was somewhat astonished at the terms into which Mr. Randall's resolution was altered, and the large majority by which it was carried, and trust you will allow me to offer some remarks to the committee appointed to carry out the decision at which the Council arrived. Had the original idea of this resolution been followed up, I should have gladly proposed my services in editing the *Journal*, and am very willing to do so now with the assistance of a sub-editor, to be approved by the Council. The bond now before you, under which I hold my office, distinctly points out my duties as secretary; and, at the time of my appointment, I stated to the Council my ignorance of practical farming. These duties I have fulfilled to the utmost of

my power, and I trust in a manner calculated to promote the material interests of the Society,\* as is indeed proved by the fact that your funded capital, which at the date of my appointment (December, 1859) stood at £10,000, has, in that interim been raised to £21,027 19s. 6d.; while the arrears of subscriptions, which I then found to be £4,804, are now £646. The annual fluctuation in the number of members is not greater than may be expected in a Society of this magnitude, as was pointed out by Mr. Thompson at the last general meeting; while the influence of the losses occasioned to the farmer by the cattle-plague, and to the Society by the consequent suspension of the cattle show for two years, must be borne in mind. This temporary diminution of numbers will, however, be more than counterbalanced by the meetings at Leicester and Manchester. It will be with the deepest regret I shall quit the service of the Society; but should the report of the committee recommend my removal from the secretaryship, I shall be glad of as long notice as practicable, time being all important to me in seeking other employment, which at my age, I fear, I shall have much difficulty in obtaining.—I have the honour to be, my lord duke, your Grace's most obedient servant,

H. HALL DARE, Secretary.

“His Grace the Duke of Richmond, K.G., President of the Royal Agricultural Society of England.”

“The Committee are of opinion that it is inexpedient to accept the offer made by Mr. Hall Dare to act as Editor of the *Journal* with the assistance of a sub-Editor. Should the foregoing recommendation be approved by the Council, Mr. Hall Dare's engagement with the Society will terminate on the 1st of January, 1869, and the Committee recommend that formal notice shall be given him to that effect, and that he be presented with a year's salary (£400) on leaving the Society's service. The Committee recommend that an advertisement be issued, inviting applications for the combined office of Secretary and Editor, at a salary of £600 per annum. The advertisement to be issued forthwith. No application to be received later than the 20th of October.”

The reception of the report having been moved by Mr. Torr, 13 votes were given in its favour and 14 against it. Mr. Thompson desiring to take the propositions *seriatim*, the President decided that the report having been negatived as a whole could not be discussed *seriatim*.

Mr. Jonas having inquired if the resolution of the Council combining the offices of Secretary and Editor remained in force, Lord Portman explained that the resolution remained until rescinded on regular motion. It was then moved by Lord Walsingham, and seconded by Col. Challoner, that the offer contained in Mr. Hall Dare's letter be accepted. The Earl of Powis opposed the combination of the two offices, pointing out the difficulty of obtaining a suitable person. He considered the salary offered (£600) too small, and moved as an amendment, that the further consideration of this motion be adjourned till November, which was seconded by Mr. Read, M.P., as he considered the subject wants more consideration. Lord Vernon supported the motion to retain the Secretary. Lord Chesham suggested that the Secretary should receive £1,000 on retiring. Mr. Turner pointed out that Lord Walsingham's motion would appoint Mr. Hall Dare to both offices. Mr. Randell and Lord Bridport urged decision

at the present meeting, and want of courtesy in the non-reception of the report. The President did not consider it as such. Mr. Thompson supported Lord Powis's amendment, the arrangements for the next *Journal* being sufficient for the present. On a division Lord Powis's amendment was lost by 17 Noes to 15 Ayes; and Lord Walsingham's motion was lost by 18 Noes to 13 Ayes. Lord Bridport then moved that an advertisement be issued inviting applications for the combined office of Secretary and Editor, at a salary of £600 per annum, which was seconded by Mr. Torr, and carried by 16 Ayes to 14 Noes.

Mr. Randell moved that the amount of remuneration to the Secretary be £400, which was seconded by Mr. Jonas, and supported by Lord Bridport. Mr. Amos recommended £300, which was seconded by Mr. Milward. Lord Bridport then moved that formal notice be given to Mr. Hall Dare that his engagement with the Society shall terminate on the 1st January, 1869, and that he be presented on that occasion with £600, which was seconded by Mr. Torr and carried.

The President then informed Mr. Hall Dare of the result, and expressed regret at the decision which would deprive the Society of his services.

**LEICESTER MEETING.**—Mr. Thompson, Chairman of the Committee, reported that the Secretary had been authorised to arrange with the contractors for the supply of refreshments to the Judges in the field and the Show-yard while the trials are going on. The Judges in the “miscellaneous” class of implements would be in the Show-yard at 5 p.m. on Tuesday the 14th inst. The Committee recommend that power be given to the Stewards of Implements at Leicester to defer the final trial of ploughs and other field implements if the state of the land shall make it necessary: the time and place of such deferred trial to be fixed by the Stewards. The arrangements for the final trial of steam cultivating implements (including the selection of the land), shall also be intrusted to the Stewards of Implements.—This report was adopted.

**SHOW-YARD CONTRACT.**—Mr. Randell, Chairman, reported that all the Show-yard works at Leicester are completed, and the surveyor certifies that the contractor is entitled to the second instalment of £1,000. The railway siding and roads and approaches are all in a satisfactory state. The surveyor had produced a preliminary plan for the arrangement of the Show-yard at Manchester, which the Committee recommended the Council to adopt, subject to such modifications as may be found necessary; and also that the Surveyor be empowered to make arrangements with the railway companies for the transit of the Society's plant from Leicester to Manchester. A tent should be provided in the implement trial field for the use of the Judges and Stewards. This report was adopted. The following noblemen and gentlemen were appointed to serve on the General Manchester Committee: His Grace the Duke of Richmond, chairman; the Earl of Powis, Lord Bridport, Lord Chesham, Lord Kesteven, Lord Portman, Lord Tredegar, Lord Vernon, Lord Walsingham, the Hon. H. G. Liddell, M.P., Sir H. Vane, Bart., Sir Edward Kerrison, Bart., Sir W. Wms. Wynn, Bart., M.P., the Mayor of Manchester, Mr. Amos, Mr. Barnett, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Clayden, Mr. Davis, Mr. Dent, M.P., Mr. Brandreth Gibbs, Mr. Holland, M.P., Mr. Hornsby, Mr. Wren Hoskyns, Mr. Milward, Mr. Pain, Mr. Randell, Mr. R. C. Ransome, Mr. Read, M.P., Mr. Sanday, Mr. Shuttleworth, Mr. Stone, Mr. Webb, Mr. Wells, Mr. Torr, Major Wilson, Mr. Jacob Wilson, and the Stewards.

## IMPLEMENT PRIZES.

The current progress of agricultural mechanics is incompatible with any permanent rule for the granting of prizes to particular classes of implements, either annually or periodically. Such being the march of improvement generally, the Royal Agricultural Society of England has no alternative left but to shape its course according to the force of existing circumstances; and such too is the lot of every other agricultural society.

Not a few implement makers and agriculturists object to the granting of money prizes under any conditions; but the arguments advanced in support of this objection, and of the contrary rule for distinguishing different degrees of merit, are not very well fortified either by scientific or practical data; for if it be admitted, as it generally is, that certain new things should have a prize, but that the old should be rewarded with a medal or empty commendation, then such admissions resolve themselves into the above demand imperatively made by the progress of agricultural mechanics, so that one solution answers both questions. It would not, therefore, be difficult to show that the two parties in this controversy have each much right on their side, but into such a discussion we do not propose dragging the reader further. Old things, to which many old-school farmers cling so tenaciously and fondly in the rear, may safely be left to take care of themselves, with whatever merit they possess; but it is otherwise in the forefront of the march of improvement, where such old things are bidding a final farewell to our homesteads and fields, their places being permanently taken possession of by the new-fangled novelties of the day.

At the present time there is no one department of the farm in which old things are not dying out, as it were, to make room for the prolific offspring of "modern innovation." It is not, therefore, with the great subdivisions into which farm implements and machinery are divided, that we have to deal; but with the progress being made in each of those subdivisions, and with the old things that are becoming antiquated. In other words, in the tillage department of the farm, old implements and machinery are being superseded by new. In the manuring, seeding, and hoeing department, things are to be found in a similar state of transition. In both hay and corn harvest a complete revolution has recently been experienced; and yet during the ensuing harvest, ninety-nine out of every hundred farmers will probably tell you that they cannot yet do without the old sickle and scythe. In the stack-yard and barn the practical man appears to breathe more freely; but even here the microscope has recently revealed such a world of "little bodies," that cling to the grain for their subsistence, that Necessity is just now taxing her ingenuity to the uttermost to get rid of such devouring mouths by numerous processes, chemical and mechanical; consequently these have their respective claims of merit that call for consideration. Dairymen, too, are on their tiptoes, looking round about them, as if awoken by a peal of thunder from a slumber of half-a-century and odds, to see what is already beginning to loom in the distance, *i. e.*, "milk manufactories" with the numerous novelties which they contain. The storm which recently raged so high relative to breeding stock and fat stock markets, &c., has given place to a calm; but in this all-important department of modern farm-practice the atmosphere is nevertheless far from being yet in a settled state, for here and there the geni of the age are singing their "lullabies;" so that before many months expire producers and consumers may see contrivances successfully carried into practice unheard-of before. Accidentally we have passed by the modern department of artificial manures; but no apology is needed for this, inasmuch as the genuine phosphatic and ammoniacal compounds invariably, weather permitting, speak for themselves. Such is a very general outline of the march of improvement in the different departments of farm practice at the present time. Each has its own peculiar claims on the consideration of the farmer, and to these we shall next briefly turn attention.

Of implements and machinery for the cultivation of land, steam-culture apparatus has its special claims. The steam-

plough, for example, is subject to improvement. This is a fact which cannot be denied. On the other hand, it is equally manifest that less or more improvement is annually being made, and so long as this is the case it would be at variance with the requirements of Science and Practice to shunt the steam-plough for a single season. In point of fact, the demands of both Science and Practice require a series of experiments every year to test the merits of steam-cultivating apparatus at different seasons, in order to determine, not only what advances have been made, but also what further advances are required.

What is thus true of the steam-plough applies to every other implement and machine in this department, and also in every other department of the farm. In other words, it may be laid down as a general rule that so long as implements and machinery are subject to improvement, and are being annually so improved, yearly experiments should be made and prizes given.

To every general rule there is an exception; so runs the common maxim; but we aver that there are few exceptions to the above. No doubt a diversity of opinion may arise as to the prospects of farther improvement being made. We might take hypothetical examples for illustration, were such necessary; but, on questions of this kind, farmers and the general public are the judges, not the manufacturer of the implement or machine. And here it must be borne in mind that the solution of the question at issue does not hinge wholly upon the actual progress made in mechanical construction—the big half, if not the more important half, of the solution turning upon the successful use of the implement, in order to satisfy farmers as to its efficiency and advantages.

To this latter half of the solution of the question of steam-culture sufficient attention has not hitherto been paid, the experiments made being so defective and objectionable as to fall short in many respects of the requirements of farmers. No doubt, the selection of the land is the best that can be made under the circumstances of the case for the peculiar district in which the experimental trials are annually held during the period of the show. But the experiments will not bear either a scientific or practical investigation relative to the twofold purpose for which they are made; and therefore the less said about the details the better; for, putting the most charitable construction upon them, the summer meeting experiments of the Royal Agricultural Society of England are, at the best, but very rough guesses as to what the steam-plough can do on the farm of this or that farmer at the proper seasons of the year for ploughing and smashing up the land: hence the practical conclusion.

We receive with much satisfaction any and every proposed change to the better. The after-harvest and winter trials now proposed may not suit so well the cravings of mere sight-seers, or the pockets of not a few farmers at a distance, as the present plan; but it must not be forgotten that such steam-plough trials are neither made to excite the curiosity of mere sight-seers, nor to meet the peculiar wants of farmers with empty pockets. And when we set both these classes aside and weigh the wants of those for whom the experiments are actually made, the facts of the case lead to a very different conclusion.

Two questions remain for a passing notice before leaving this department. *First*, is sufficient encouragement being given to other steam-culture implements besides the plough and grubber? Ought not prizes to be given for steam-rollers, steam clod-crushers, and steam-harrows? And in the next department, for steam seed and manure drills, and broadcast machines?

*Second*: As we progress in the substitution of steam-power for horse-power, and increase the annual number of experiments with the former, it is but in accordance with the requirements of both science and practice that the length of the periods between the trials of the latter (horse implements) should be increased. In point of fact, the attention of the great bulk of the agricultural body is now so engrossed with

steam-culture that they can well afford to shelve horse-culture altogether for the future. As yet, a rule so sweeping as this may not be in accordance with the declared functions of any of our national or even local societies. This may be granted, and yet it may nevertheless be affirmed that the rule is fast working its way into general application.

Much of what has been said about steam ploughs, grubbers, seed and manure drills, applies in principle to mowing and reaping machines, hay and straw elevators, with other machines of hay and corn harvest, subject to improvement, and which are annually being improved. If any patentee or manufacturer is very particular, we see no great objection to leaving out pitchforks, hand rakes, common ladders, harvest carts, and other old well-tried things altogether, making an exception only of real novelty, when it enters appearance; but mowing and reaping machines must be annually tried for a long time to come, and that for the two-fold purpose already noticed under the steam plough, and different prizes awarded to them according to their merits.

In the barn department the period between the trials of thrashing machines, chaffcutters, portable and fixed engines only adapted for actuating the same, with turnip cutters, corn and cake breakers, and old machines of this kind, may be increased in length. But in this department an exception requires to be made of corn screens, scouring machines, and other like novelties under the pioneering hand of Improvement. We have here under consideration a functional distinction between different machines sufficiently far apart to demand a corresponding distinction in the awarding of prizes for the two-fold purpose at issue. Hence the conclusion at which we arrive under this head.

Hitherto, although dairy affairs formed a frequent topic of discussion at its weekly council meetings, in Hanover-square, the Royal Agricultural Society of England has not given much encouragement to progress in other respects. And the same may be said relative to the marketing of breeding-stock, fat-stock, and dead-meat, although few departments of farm practice engross more of the farmer's attention.

There has manifestly been an oversight in this, which may be termed the commercial department of farm practice. We are even apprehensive that when the subject is closely investigated something worse than mere oversight will be found; for not a few of our great ones shy, and even turn tail, the moment any proposition is enunciated for bringing the agricultural body in contact with the inhabitants of our large manufacturing and commercial towns, as if experience had taught them that the latter are too many for them in any commercial transaction.

The day was when country folks had some reason for shying at townsfolks, but that day has gone by; farmers, as a body, being now able to hold their ground with equal-handed firmness and success. At the present time they are even showing themselves masters of their position as the primary and leading body in the political economy of the country, and the true topics under consideration, viz., the commerce of dairy produce and the commerce of live and dead meat, occupy a prominent place in their public and private deliberations in every corner and province of the kingdom. They are topics which claim the special patronage of the Royal Agricultural Society, and that of all our other societies and clubs, with a view to cultivate chemical and mechanical progress in each of these branches of farming. Both propositions are great national movements having for their object the joint economy of labour

and capital, so that they merit the timely consideration of those political economists who are now discussing the rights of landed property, large and small farms, and so on—public questions whose details we cannot at present entertain.

Milk manufactories are of several kinds, according to the nature of their working details. In some of the large American and continental establishments the whole of the milk is produced by the proprietor's or farmer's own herd of cows. In other examples, it is purchased from the farmers in the district. One converts the cream into butter—the skimmed milk into pork; another, the whole milk into cheese—the whey only into pork; a third adopts both practices; a fourth sends a great portion of the cream and whole milk to town. There is thus a considerable diversity of practice, with a corresponding diversity in the dairy apparatus and utensils for carrying the same into effect, in all of which the manufacturer has a control over temperature and everything else comparatively unknown in small concerns at the homestead of the farmer. Such are the advantages in their favour, that it is even said a farmer may sell his milk, and buy what butter and cheese he requires for his own use, with profit. It would be uncharitable to draw any comparisons between such manufactories and the antiquated dairies of the vast majority of farmers at the present day. Such being the general outline, the reader will readily perceive the patronage which this new subdivision of labour and branch of industry requires, so as to increase their number and effective operation, in order to meet the demands of farmers, many of whom may feel it their interest to produce more milk than they now do, were a market for it thus to spring up at their doors.

Our commerce of beef, mutton, and pork is equally subject to improvement. Of late years, much encouragement has been given, and many improvements made in the art of production; but the roundabout way in which farmers convert this description of farm produce into hard cash is yet deplorably antiquated.

It were difficult to imagine any branch of human industry more out of date than our cattle markets and dead-meat markets. And yet when we put the plain, practical question, What has the Royal Agricultural Society done, and what is it now doing to encourage improvement? we are at a dead loss how to return a satisfactory answer in harmony with its chartered privileges and duties. To say that nothing can be done to stimulate progress is tenfold worse than no answer at all. Before the establishment of milk manufactories nothing could be done with milk in the country far away from towns. Some give it to the pigs, or convert it into cheese which nobody would eat. But no sooner do such establishments make their appearance than everybody is surprised they did not appear sooner, so simply manifest and successful is everything about them. Just so it is with our beef, mutton, and pork. We produce them in abundance, and would produce much more could we only see our way clearly to a more intelligent economy; but this we cannot do, although suspicion is becoming stronger and stronger every day that an incalculable loss is being sustained. Consequently farmers keep grumbling, as this all-important branch of commerce continues to flow on in its old antiquated channel—like the stream in the desert, growing beautifully less and less, as it sinks in the porous substratum below unseen, and rises in the atmosphere above in the form of vapour invisible! All this is plain enough; but it weighs heavily upon the shoulders of the farmer and the productive resources of the country.

ENGINEER.

## THE WORKING AND USES OF AGRICULTURAL MACHINERY.

At the quarterly meeting of the Boroughbridge Agricultural Society, Mr. SCRUTTON said: The subject allotted to me has been on agricultural implements and machinery. As this subject is too extensive to be treated in a short paper, I shall confine myself to the working and uses of agricultural machinery. Firstly: The necessity of reaping and securing our grain crops. It is of great importance, though it is widely modified as to time, labour, and precariousness, by the nature of the climate and the character of crops. In reaping our grain, it has only occurred within the last few years that a

march of improvement has come to our notice from the sickle, which has been in use for thousands of years; next the scythe was introduced, which was not an improvement on the sickle: it was a most untidy way of reaping, making great waste: the only benefit derived was getting it quicker done and sooner ready for the stack-yard. Now we have reaping machines nearly brought out to perfection, which, a few years ago, were considered by the agricultural societies prizeless machines, but, through the skill of our mechanics and hints given them from our agriculturists, have come at the proper mechanism. We

owe no little sympathy to our implement manufacturers, if we look back how they have tried to invent machinery for the cheaper mode of farm cultivation. We now have reapers quite equal to the sickle, which was a cost of from 10s. to 16s. per acre reaping. Our crops can now be reaped with a reaper at from 6s. 3d. to 10s. per acre, including raking and making it, quite equal to the sickle reaping, leaving no rough stubble to contend with afterwards, which is now made into manure; also, the great benefit derived when a general harvest comes hurriedly on, and the weather for it is capricious and exceedingly changeable. The farmer has daily and nightly about as much need of skill and energy, vigilance and continual self-possession, as ever Wellington had in any three months of his Peninsular campaign. It is needless for me to say anything as regards the working of reaping machines, as they are made so simple to work, nor can I recommend any particular maker's reaper—the principles are so nearly allied. I can only say that in making a purchase of a reaper do not get a light-made reaper: you cannot get power in a light machine. To cut heavy crops a three-inch stroke in the crank is the best for cutting clean, and a six-inch stroke in the crank is easier draught for the horses, requiring less speed, but does not cut so clean a stubble, which is easily accounted for, that a slow cut is not equal to a quick one. Have your reapers examined in due time before harvest and put in good order, as delays in this respect are troublesome, and expensive to have to repair when they should be at work.—Secondly comes the time for autumnal cleansing. No time should be lost after the crops are carried, our part of the country, being a northern district, not having the same advantage in this respect as the south; also twitch grass makes great progress in the roots after the crops are reaped. The cultivators mostly in use should be those with the three-inch times: first, to loosen the soil and make it in better order for crossowing with the broadshares, cultivate your land a good depth, so as to extricate the twitch grass; then use a drag with teeth well forward, so as to lift any weeds the cultivator has not brought to the surface. All seasons are not suitable for this process of cleansing the land of weeds; nevertheless strive to get it done, as frost will, to a great extent, kill twitch grass when exposed to it. Great benefit is derived by scarifying the land that is to be cleaned of weeds, and not to plough in the spring when the land is wanted to sow with either corn or turnips, particularly the latter: if strong loams are to be ploughed in the spring, and the winter tilth or moisture lost, it invariably is never regained. The chain harrow is an indispensable implement for using, in the process of dashing the soil from the twitch grass on strong land that has been cultivated in the autumn. It is not amiss to put on the chain harrow after a frost, if there be much twitch on the land, but the land must be sufficiently dry. Much benefit has been derived by the use of the scarifier, over the old system of ploughing and harrowing, as every harrow, be its particular construction what it may, fails to bring up the weeds from any considerable depth. The scarifier may be termed the king of harrows, or an intermediate implement between the plough and harrow. Thirdly: Having cleaned oat, bean, and pea stubble intended for wheat, with the broadshare, and the time approaching for wheat sowing, it is necessary to get the plough to work, which, in its perfection, is the foundation of good husbandry. Very few bad ploughs are made now: there is a marked difference from the old-fashioned ploughs with short straight handles, short mouldboards, setting their furrow upon an edge, being incapable of turning the soil, and merely effecting a stirring or breaking up. A plough should set its furrow at an angle, to be in the best form for harrows, making plenty of tilth for the seed; avoid laying your furrows too flat, which is regulated by the width of furrows taken; if the land be clear of stones, use a share the width of the furrow you take, so as to cut up all weeds; if not, thistles and various kinds of weeds will soon appear in the plough seam. There are few implements now in common use that have undergone more improvements than the plough. Our ploughing matches have made great success in this department of farm practice; good ploughboys are to be found on nearly every farm. A sharp active boy will do more work now and much better than men could do before the wheel plough came into public use. Fourthly: Having prepared the land for seeding, the steerage drill being an implement of much importance should on no account be omitted to be used, it being an economiser of seed, as well as the

exactness in the rows being in a true position for horse-hoeing. A drill of about eighty inches in width is a useful size: it can be made to drill four rows of beans, twenty inches apart, which, when a five-foot reaper is at work, will be found to take three rows of beans and reap them tidily. If the rows are shed by the reaper the work is not so well done. After the autumn sowing is over, the digging breast should be attached to our ploughs, which, in its form, leaves the land in a broken, rough, and exposed surface for the frost. Fifthly: Machinery, in its application to manufactures, consists in the addition which it makes to human power, the economy of human time, and in the conversion of substances apparently worthless into valuable products. The same applied to agriculture consists chiefly in steam-thrashing machines, which is a saving of human power and economy of human time over the old system of thrashing. Next comes the root pulper, an implement applied to bring worthless substances into valuable use; also a great saver of our root crops, which is so costly to produce. Chaff, which formerly used to be buried in pits to get rid of weeds, by the use of the pulper has become, by being mixed with roots, a valuable counteractant on the bowels of cattle, as well as making our roots go further. By the use of the chaff-cutter, chaff is substituted with cut straw for mixing with meal for horses. A turnip-slicer for sheep forms one of our most indispensable implements, for the fattening of hoggets and other sheep on turnips in the winter, thus in wet weather being a great saving over the old system of eating turnips on the land unpulped, which caused much waste by the tramping of their feet over them, until they would not eat them. Various other machines are to advantage, such as grinding mills. Sixthly: In the early spring time of the year, we must look to our horse-hoeing. The practice of cereal-hoeing is all but universal in modern agriculture. It dates its adoption with the introduction of drill-husbandry, and is a most valuable aid in the production of a fine and profitable crop; it is a great help to the cleanliness of the soil, and assists the healthy growth of the plants. It has been found profitable to hoe the weediest portions of the farm by hand-hoeing. Why should we now neglect to hoe when practical and scientific skill has improved and brought before the public an implement for use at so trifling a cost compared to hand-hoeing? It can be done at 1s. 6d. per acre, and more effectually; whereas hand-hoeing costs about 6s. per acre and is only imperfectly done. The best time for hoeing is as soon as the corn is high enough, but not to cover with the loose soil. It is injurious to the plant to hoe when corn gets high, as the roots are spreading in search of additional food to promote their more vigorous growth, and if cut off with the hoe will be an injury to the growth. The true principle of horse-hoeing consists mainly in the breaking of the surface soil and the extirpation of weeds. The greatest advantage over the hand-hoe is in consequence of one man, two boys, and two horses being able to do from 12 to 16 acres per day, as necessity requires. The advantage of doing a large portion in one day is to get through the work in fine weather, so that the sun will have its influence in killing the weeds. Seventhly.—Implements for the preparation of green crops.—The common harrow, to loosen the surface soil; next the chisel-harrow is a valuable implement for breaking and loosening the soil; then the drag or cultivator, to get deeper into the ground, and to form more loose soil for ridging. A cheap-made implement, called the bruiser or scrubber, used in timely application after the drag, will produce, in the generality of soils, a tilth that cannot be excelled, leaving the soil in a much lighter state for the ridge-plough than any other kind of implement. Drills or ridges may be opened out with either the double-mouldboard plough or the common plough. The last-named plough can be made at a trifling cost, by putting a thin iron mouldboard on the left side of the plough, with a screw to adjust the width of the plough. A small iron attached to the plough, to mark the width of the ridge, is very useful to keep the ridges even. A light-made drill for mangold wurtzel and turnips, with concave rollers to fit the ridge, is the best for drilling with perfect exactness on the centre of the ridge, and a great improvement on the old system of drill with fast coulters, as often depositing the seed on the ridge side as anywhere else, and making it difficult for the ridge horse-hoe to work. A light roller is a very useful implement to roll the ridges after the seed is sown, and to press firm the seed amongst the earth, which so often admits the parching air and extracts the

moisture. The rough roller is preferable to a smooth roller; for when heavy rains come it is not so liable to fasten the soil, on account of its leaving an uneven surface. Eighthly.—Implements for mowing grass and hay-making.—The mowing-machine is quite universal now, and used on almost every farm. It excels the scythe, gets nearer the ground, by the aid of a flexible beam; it can be done at a cost of 3s. 6d. to 4s. per acre, where in many districts 6s. was paid before the mowing machine came into public use. Not only is it a saving in the cost of mowing, but it does its work much quicker. The old adage is, "make hay while the sun shines." It is absolutely frightful to see the quantities of hay lying before cattle in some places, that nothing but great hunger can tempt them to eat, being fit for nothing but the dunghill. Hay wants getting quick and kept moving by the haymaking machine, and it will keep its weight and colour, its proper amount of juices, and that delightful aroma so sought after by cattle. Let it lie to "make itself," and the sun will soon scorch all that on the top, while there is no making whatever that underneath; time and quality are thus lost, when the crop might have otherwise been well secured.

Mr. SCOTT said he would recommend to all young beginners the necessity of being very careful in the selection of proper implements to use upon their farms. It would be well for them to consult their friends, and also the reports of the various agricultural shows. They must go to the best makers for their implements. To one maker for their ploughs, to another for their drills, and not obtain all the implements they required of one particular maker. They must choose the best makers for the particular implements they wanted (Hear.) How different was the state of the blacksmith's shop now to what it used to be! Formerly they saw nothing but the vice, anvil, and bellows; but now, at almost every blacksmith's shop, there was a small steam-engine at work, and agricultural implement-makers had made rapid strides in improvements, and they had displayed skill and ingenuity in the manufacture of locomotive engines. He thought that Mr. Scruton had not alluded in his lecture to the digging plough, one of the finest improvements effected within the last few years. There was the chisel-harrow, too, which was a most valuable implement.

Mr. BAINBRIDGE said that there was one point with regard to implements which ought not to be overlooked. They ought to be properly taken care of, and not thrust into corners or left in the middle of the field to become out of order. He had seen a reaper standing out last winter. It was the height of folly to use implements in this way, to leave them unpainted, and to let careless boys have the charge of them. Agricultural implements, generally speaking, required far more care than they received at present.

Mr. APFLEYARD said that the water-drill for turnips was not mentioned in Mr. Scruton's paper. He had used the water-drill on his farm, and it answered well, and he had also experimented with a water-cart upon an acre of turnips in one of his fields. The water-cart went over two rows of turnips at a time, and they had been watered every other day for some time. He should have a very good crop of turnips upon this acre of land, but as to the rest of the field, which had not been

watered, he had not yet seen a turnip-plant make its appearance.

Mr. SCOTT said that he had used the water-drill with success upon his farm for the last fifteen years. He was of opinion that the water-cart, as alluded to by Mr. Appleyard, would be of great service, because it would act mechanically in the equal distribution of the manure.

Mr. HARLAND inquired of Mr. Appleyard if he rolled the rest of the field which he had not watered?

Mr. APFLEYARD replied in the negative.

Mr. HARLAND said that if Mr. Appleyard had rolled the soil it would have become consolidated. If the roller had followed the drill it would perhaps have done as much good as the watering. He found upon light soils the use of the level drill beneficial, and it was the kind of drill he approved of. It would act well, fitted with a tillage-distributor, and followed immediately by a light harrow and roller; yet it might be that he should think differently if a plentiful supply of water was near the land.

The Rev. C. H. SALE said that thrashing-machines had been a great boon to the agricultural labourer. During the early part of his career as a clergyman, he had known many strong young men "killed off" in the prime of life in thrashing by hand. Wages were high, and these men were stimulated to over-exert themselves; the consequence being that they died of the lung complaint, by inhaling the dust from the thrashing. Many men, by thrashing in a barn for eight or nine months together, were at length attacked with the lung disease, and died at an early age. Agricultural machinery required something like skill and intelligence in its management, and it therefore behoved the farmers to do all they could to educate their labourers and servants. Men who were uneducated and dull must mismanage machinery, and it stood to common sense that those employed on farm-work should be properly trained. On every farm there ought to be at least two or three men having a smattering of mechanical knowledge, to prevent the others from getting into error in the use of agricultural machinery.

Mr. SCOTT said that the mechanical construction of agricultural machinery was such that it required the men engaged in its use to be very careful and to pay particular attention to oiling the various parts, and keeping the whole in proper working order. He had used a reaping-machine since 1852, and he was now using more than one, and they answered their purpose remarkably well. Mowing-machines for grass were more efficient than reapers, as they were more simple in their operation. The raising and lowering of a reaping-machine when in motion was a great improvement.

Mr. SCRUTON said that four years ago he introduced at Goldsborough a grass-mowing machine. It was very much liked, and he soon got a second, then a third, and at last a fourth, as orders for cutting grass came in so fast. At first his young men were ignorant as to these machines, but they soon became acquainted with their use; and with these four machines, in one season, he cut 900 acres of grass, and not the slightest fault was found with the way in which the work was done. The farmers liked these machines so well that they purchased them of him.

## POOR RATES ASSESSMENT.

The select committee appointed "to inquire into the assessment and collection of poor rates and other local rates and taxes in England and Wales" have issued their report. The conclusions at which the committee have arrived are expressed in the following series of resolutions:

"1. That every local authority entitled to raise any money by means of local rates should make a requisition on the overseer or other proper officer for the whole amount required to be paid, so far as the same can be estimated, for the period of one year, commencing at a fixed period.

"2. That such requisition should be delivered to the overseer, or such other officer, a reasonable time before the commencement of the year, to enable him to make a rate at that time.

"3. That such requisition should state the amounts which

may be required for the several purposes, if more than one, for which rates are authorized by law to be made.

"4. That the overseer should, on receipt of all the requisitions made on him for the year, make one consolidated rate sufficient to satisfy all such requisitions.

"5. But when all property described in the rate-book is not liable to be rated uniformly for the purposes of all such requisitions, such entries shall be made in the rate-book as may be necessary to show such difference in the rate.

"6. That the rate should be payable by not less than four equal quarterly payments, and be collected and enforced accordingly.

"7. That where the rate exceeds 1s. in the pound, the person in occupation of any tenement let at a rent payable

oftener than quarterly may elect to pay the rate by monthly instalments.

"8. That, in addition to the rate-book now prescribed, a book to be called the 'Instalment Rate-book' shall be provided in a form to be prescribed by law, in which the name of each occupier electing to pay monthly the amount of the rate, the amount of each instalment, and the time when payable, shall be entered.

"9. That, when any necessity shall arise during the year for any rate above the estimated annual charge, a special rate shall be made, and be collected with the next following payment.

"10. That a demand-note should be left with each rate-payer, on the rate being made, stating the amount of the requisitions, the rate in the pound for each purpose, and the period for which the rate is made, the rateable value of the premises, amount of the rate thereon, and of each payment.

"11. That the overseer should be empowered, at any time after a rate has been allowed, to amend the rate-book, with the sanction of the justices, by omitting the name of any person unduly inserted, or inserting the name of any person unduly omitted.

"12. That where any premises, being vacant at the time of making the rate, shall become occupied before the next rate shall be made, or any change shall take place in the occupation during the year, the overseer should make a supplemental rate in respect of such occupation.

"13. That paid collectors should be employed where necessary to collect the rate, for such remuneration, by way of salary or commission, as the local authority making the requisition shall consent to allow out of the amount thereof.

"14. That the overseer and collecting officer should pay over the rate as collected, and account for the same and for arrears thereof, at such times and in such manner as may be prescribed by law, and the same should be enforced by a summary proceeding before two justices of the peace.

"15. That every change in the ownership and occupation of premises should be reported by the collecting officer to the overseer, and every increase in the value of the premises should be reported to the Assessment Committee.

"16. That the Commissioners for the Assessment of Local Taxes should deliver yearly to the overseer, or other proper officer, a schedule of the taxes to be collected from tax payers in the parish (except the assessments of the special commissioners of the income-tax).

"17. That the collecting officers should collect, account for, and pay over the taxes according to such directions as they may receive from the Board of Inland Revenue, on being allowed such per-centage thereon as may be allowed for the collection of taxes.

"18. In the event of any loss arising from the insolvency of a person liable for both rates and taxes, or from the embezzlement of a collector, the priority of claim on the part of the Crown on the available fund should be preserved, subject to which the loss should be borne rateably out of the several requisitions for which the consolidated rate was imposed.

19. That the owner should be rated in the following cases:  
a. Where the tenement is let furnished; b. Where the tenement is let in apartments, but the occupier should be permitted to claim to be rated and be rated in manner prescribed by the existing law.

"20. The owner should be deemed to be any person receiving or claiming the rent of any tenement, or receiving the same for the use of any corporation aggregate, or of any public company, or of any landlord or lessor, who shall be under disability; or for the use of any person who shall not be actually resident within twenty miles from the parish in which the tenement is situate.

"21. That the power of excusing persons from the payment of rates should be transferred to the board of guardians, and any allowance of exemption from rates on the ground of poverty should be considered as out-door relief.

"22. That the board of guardians, before hearing any application of an occupier for excusal, shall give notice to the owner of the tenement occupied of the time and place appointed for hearing the application.

"23. That the owner of every tenement, the occupier of which has been excused payment of rate on the ground of poverty, shall be liable to two-thirds of the rate.

"24. That where premises are let for shorter periods than a year, the assessment should be carefully revised, so that, in fixing the gross estimated rental under the Assessment Acts, proper deductions should be made from the enhanced rent charged by the owner, to cover the risk and cost of so dealing with his property.

"25. That when the owner is compelled to pay any portion of the rate, contrary to his agreement with the occupier, he shall be entitled to recover the same by distress or action from the occupier; and when the occupier shall be compelled to pay the rates, contrary to his agreement with the owner, he shall be entitled to deduct the same from his rent, or to recover the same, as well as damages, for any distress he may have suffered by action from the owner.

"26. That so much of any public or local Act as relates to compositions for rates for public purposes should be repealed."

### T I P T R E E F A R M .

A deputation from the Midland Farmers' Club, consisting of Messrs. J. Ford (the president), E. Yates, H. H. Chattock, W. Brewster (Stretton), C. L. Browning, J. France, T. Horley, R. H. Masfen, Shenstone, J. Smith, J. A. Williams, M. Williams, and J. B. Lythall (secretary), visited Tiptree Hall Farm by invitation. The deputation from the Midland Farmers' Club was met by Mr. Moore, chairman of the Farlington Farmers' Club, with Mr. Dyke, Mr. Humfrey, and about twelve members; Mr. Bridgland, chairman of the Maidstone Farmers' Club, and twenty-five members; and some others also accepted invitations.

From the character of the soil of the county and the general healthy appearance of the wheat crops of the district, it was expected that the Tiptree wheat would present a very creditable appearance, but none of the members of the deputation were, we believe, prepared to see so much good wheat for the whole growth as Mr. Mechi showed them. The total extent of land in wheat is 72 acres, the farm comprising only 170 acres, of which 13 are in pasture.

Mr. MECCHI having stated at Birmingham that he made 18 per cent. on his capital of £16 per acre, and would have preferred to increase his capital to £25 per acre, was requested by Mr. MASFEN to give his opinion as to what per-centage he would obtain on this additional capital. Mr. MECCHI, in reply, stated that last year he had to sell hay and straw, which, had the additional capital been forthcoming, he should have consumed with cattle, thus obtaining a much greater quantity of manure, both liquid and solid, and thereby increased fertility and yield. He considered, if he had employed £1,500 more, he should have made 20 per cent. on the whole capital.

A discussion took place, in which Mr. HORLEY and Mr. BREWSTER took part, as to Tenant Right, the general opinion being that it was futile to expect farmers to lay out money in the manner it was done at Tiptree, or to follow in Mr. Mechi's steps, without security of tenure or ample compensation; Mr. FORD requesting Mr. Mechi's opinion as to the best way of attracting capital to the land, and obtaining security.

Mr. LYTALL also stated that in the great majority of agreements in the Midland counties the tenant-farmers were so tied down to particular courses of cropping that they could not farm as Mr. Mechi did, even where they had the inclination and the capital; and he also spoke of the loss caused in corn and root-crops by the large quantity of hedge-row timber in the Midlands.

Mr. HALLETT would give his agent the management of his best farm, and make it the standard for his tenants to farm up to, as long as it paid; to which the farmers present objected, thinking the agent should rather have one of the worst farms to improve.

Mr. MECCHI, in conclusion, said that no doubt the main question involving investment of capital in the soil was security of tenure. He was decidedly in favour of a long lease, or an equitable Tenant Right. Long leases were impossible in all cases, and he thought landlords should be most particular in looking to character, conduct, improving business habits, and capital of tenants, and then bad farming would soon become the exception.

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

## MEETING AT LEICESTER.

The resuscitation of the Royal Show must have been a question of some moment with the management; but it is one that has been very satisfactorily solved. The interest in these occasions has by no means died out on the fallows, and seldom has a meeting been better supported than that at Leicester. The champion breeders of most kinds of stock came in something like their pristine force, the public came in greater numbers than ever, and the implement makers spoke to the briskness of trade and the great promise of the opening days. In fact, the only doubt expressed, and this was a very general feeling, went to impugn the policy of cutting the week into two, and driving people away on the Saturday with the idea that they would ever come back again on the Monday. Let the trials of machinery extend over ten days or a fortnight; but if the cattle show proper commence on the Tuesday and finish on the Friday, it would amply answer its purpose, as such an arrangement would be far more convenient to a great majority of the visitors. But there is and long has been a certain peculiarity in the action of the Council, which goes to make alterations that were never needed, and to resist improvements that have been long pressed upon its attention.

If a really magnificent show-ground and the most brilliant of weather would tend to ensure success, the Royal Society was so far favoured; but, as has already been inferred, there were the still more substantial attractions of large entries and much merit. In some of the sections, such as the Leicester, Southdown, and Shropshire sheep, the Devon cattle, and certain varieties of the pig, these breeds have seldom or ever been so well represented; while the Shorthorns, if only good in places or classes, yet reached quite to an average of excellence, as the riding horses are fairly training on into a very creditable, and of course at the same time into a most popular, feature of the exhibition. The very catalogue went far to assure one of the worth of what there was to see, and in the first class of cattle there were the names of owners and animals almost equally famous. These old bulls indeed, with many a winner in the ring, took a deal of judging and drafting; but the award ultimately arrived at struck the key-note, and the Booth blood was altogether in the ascendant. Commander-in-Chief took a second prize as a yearling at Plymouth, where he was but little fancied, save by the Judges, one of whom was here again in office. The Commander has gone on growing and improving, and is now certainly a very handsome animal, with a good fore-hand, and fine length, but with rather a lack of masculine character about his head, and with his tail set on high and lumpy. A still neater bull, so much so as to be pronounced almost "pretty," was the Heir of Englishman, who has been a frequent winner in Scotland, and that was considered by many to be the next best here. The judges, however, went for Mr. Peel's white, a not very taking bull until you study him closely, and who proves better in his standing than when led out. There is a want of freedom about his carriage, and the hand we should say had more to do with his place than the eye, for no doubt the award was something of a surprise to the lookers-on. The third prize, Huntsman, has many good points, the more especially forward, beginning with a capital head, in which respect he was superior to his fellows; while Mr. Lynn's Prizeman, Mr. Pawlett's

Baron Killerby, and Mr. Christy's Duke of Grafton, that have been all winning about the country this summer, were kept in or "about" for some time, although, as was very evident, with no chance of reaping anything higher than a commendation. The class of two-year-old bulls contained some of the worst animals in the show, and nothing could look like a greater burlesque on the improved Shorthorn than such things as Prince of Rosedale or the Northumberland Knight. The indifferent altogether preponderated, and after having seen them go once round we put our mark on Baron Geneva as a long way the best of them. He is deep, round, and handsome, of a good roan in colour, and moves well, so that the judges could not keep their eyes off him, and Mr. Adeock "won easily" if ever such a phrase was admissible. That now well-known exquisite, the pretty Charles le Beau, again got into his favourite place of second, while Mr. Stratton, even in such company, could reach no higher than a commendation, but his young bull was thought more of out of than he was in the ring. The best Shorthorn bull in the show was the best of the next class, the Irish yearling Bolivar, the best of all the bulls at the last Dublin show, and of wonderful quality, with the finest silky coat, a long level frame, and so forth. In fact, there is scarcely anything against him but his colour, so dingy and rusty as to really detract from his otherwise handsome appearance. Lady Pigot was again second with another of her strolling company, and a plain cloddy animal from Gloucestershire lacking all the fashion of the other two put third, as the judges here hardly held to their line. The calf classes do more harm than good, but there were some nice promising young bulls, if these be not spoiled in the making, and Mr. Foljambe first and second for quality and style, with lots of critics ready to reverse the judges' decision; but this is no uncommon case where the same man takes all the honours. In fact, in Yorkshire, the very owner will commonly uphold the second, knowing well enough that the fact of a "first" will always speak for itself.

One of the sweetest, straightest, and altogether most charming cows out for many a long day is Mr. Booth's Lady Fragrant, who still gathers graces with her years, and is really ripening into perfection. Her head and "expression" would furnish the study for a picture; and so far as the chief prize could be concerned, there was no competition. Still the Queen of Rosalea is a lengthy, handsome animal, that has previously beaten Jolly Queen, as to our thinking she should have done at Leicester, and it certainly was not for want of "a show" if she did not. A gaudy, vulgar, steery animal, from Leeds way, was made the reserve number, and some further commendations liberally scattered. But if the cow class were a good one, Lady Fragrant is a clipper. Against but little competition the three prize two-year-old heifers are all good, and we have previously spoken to the merits of the Dame of Rosalea and Thoughtless, but Her Majesty's entry has never been out before, so that she may show fresher than her competitors; as indeed Lady Pigot looked rather out of luck, most probably from the peregrinations to which her stock have been subjected. There was a very large and excellent entry of yearling heifers, led off by Mr. How's Lady Anne, that has been winning all over the country, at Downham, Newmarket, Oundle, and Lu-

ton, and to whom we have all long since taken off our hats as "a beautiful lady-like creature." We believe this heifer has never been beaten, yet she has a long pull amongst a lot of yearlings, being now close upon two years old, although there were even her seniors here, Mr. Garne's third prize, Duchess of Towneley, being still nearer to the limit. With Mr. Booth second and the reserve, the great merit of the first heifer may be easily imagined, but there were others worthy of notice, although but few commendations were appended. Mr. Stratton got a place at last amongst the calves, where Lord Penryn won with a particularly neat one, and Mr. Beever deservedly gained some further commendation for the Shorthorn herd he is cultivating on the banks of the Wye.

This no doubt sounds very like treason, but the Hereford breeders must show a better front if they mean to hold their own. There was no breed which attracted so little attention at Leicester as the white-faces; and there should be no surprise if it were so. The entries were generally scanty, and in many of the classes there was no competition beyond the one or two prizes the judges had at their disposal. Moreover, the sample was not a very brilliant one; and when we remember the grand shows of Herefords that we have witnessed, we are the more inclined to condemn the apathy into which breeders appear to have fallen since the meetings were for a time set aside. The Sir Benjamin blood is very strong in the prize-list, and Mr. Rogers' old bull, a very good one, comes on both sides of winning strains, though Mr. Arkwright has the best of what there is here. His cow is low, lengthy, and handsome; his young bull very promising, and his yearling heifer very perfect in her frame, but not so nice about her head. Mr. Plimley also shows a clever heifer in an older class, where she has no difficulty in beating two very poor things from Mr. Prosser; but as there are three prizes and only three entries, everybody gets something. There was only one bull-calf sent, and only four yearling bulls entered. Her Majesty, it will be observed, still maintains her Hereford herd, Mr. Duckham is an exhibitor, and a young bull was sold early to go to Ireland, but, nevertheless, if any one can be said to have enjoyed the cool shade on Leicester race-course, this must have been a Hereford beast.

Any weakness amongst the white-faces was rendered the more remarkable by the comparative strength of the Devons, of which there was really a capital show. In some of the classes, in fact, the competition was considered to be almost too much for the judges, and nowhere were the decisions more warmly canvassed. It appears that a very experienced man, Mr. Franklin, being unable to come, the Council put on his son, and it was thought the only west-country man was continually out-voted. The first lot of bulls, certainly full of good animals, took a deal of judging, and it appeared at one time that the trio never would arrive at an opinion, and, when they did, this was by no means endorsed outside. They made their best of all a smart bull of Mr. George Turner's, that was also first at Falmouth, and they put a yet more clever blood-like bull from Flitton third, with one of Lord Falmouth's between them; as it was assumed that the local man had to remonstrate very strongly before he could obtain thus much. Still the class, no doubt, was very "trying" throughout; and were we to find fault, it would be rather with the terribly high and over-done condition in which some of the animals were exhibited, than with any want of actual merit. Mr. Bodley's bull was quite worthy of a prize, and it is significant to see that almost all the honours went to the true or North Devon type. There was only one entry of two-year-olds; whilst the Somersetshire men had all the best of the yearlings, if Mr.

J. A. Smith's high-bred looking animals are open to the comparative reproach conveyed in the term. It is when the blood-red begins to lose his colour, and fade into a dull dun or yellow, that we come to think there is need to go back to the old sort. However, at Leicester the home Devons by no means lacked size; and the Somersets, with an exception or so, seemed to be gathering more style and quality. The Bradford Peverill herd was first again with cows, and the whole class of heifers, in milk or in calf, was commended. There was not much competition in the yearling or heifer-calf classes, but the young things sent were all beautiful specimens of their kind; and there are few more beautiful animals in creation than the round, compact, active, but thriving Devon; and here again her Majesty gives her countenance. The Shorthorn, indeed, is almost the only beast that has not made much mark from Windsor Castle.

Possibly from the neglect with which this qualification has so long been treated by our leading breeders, a certain reaction has set in, and there is now quite a run on good milkers. Although the entry of Channel Island Cattle was not large, the Jersey judge was quite satisfied, as amongst the animals were many winners from the Island. Mr. Pallot's best bull was considered to be a very superior specimen of the Jersey, uniting true symmetry with more size than is often seen; as Mr. Gaudin's second was also pronounced to be very meritorious. The fifteen cows were really all good, many of these being exhibited by English gentlemen, if they could stand but little chance against the Island breeders; whilst the gem of the sort was Mr. Pallot's two-year-old, not only very graceful in her appearance, but with her milking properties finely developed. Of course the call was for Jerseys, but Lady Berners' highly-commended cow is a Guernsey; while for anything like a distinguished animal prices ruled high, forty or fifty guineas being readily asked for a cow; but then at Mr. Dancy's sale more money was often made, and we doubt if Mr. Dancy could have won at Leicester.

There were five entries in four classes of Sussex, with only two exhibitors—Messrs. Heasman and Mr. William Marshall; and of course this breed will be dropped out of the list into the other established breeds, chiefly made up here by Midland Longhorns and Norfolk Polled. The Longhorns were indisputably good, as in more numerical force than usual; and the Polled milkers scattered here and there throughout the classes had no chance in such company. A mixed class must be but an ungrateful one to judge; and considering that Leicestershire has always been their vantage ground, the Longhorns, if only by the way of a curiosity, might have had some rank of their own.

In a nicely-formed ring, which allowed the public to get near enough to the horses to see what was going on, business commenced on Thursday, at eight o'clock; one end being taken up by the judges of riding horses, and the other by the agricultural bench. Nine out of the ten thoroughbred stallions entered as suitable for getting hunters made their appearance in the ring—Ivanhoff, by Muscovite, out of Blackbird by Irish Birdcatcher; Lancer, by Heapy, out of Cairngorm; Angelus, by Orpheus, out of Nutmeg by Nutwith; John Halifax, by The Ugly Buck, dam by Annandale; Rouge Dragon, by Windbound, out of Paradigm by Paragon; Cawood, by The Cure, out of Brandy Snap by Muley Moloch; Naseby, by Cotherstone, out of Victorine by Speculation; Hurrah, by Newminster, out of Jovial by Bay Middleton; and General Hesse, by Nabob, out of Lady Alice by Lanercost—the absentee being King of the Dale, by Annandale, out of The Nugget by Nutbourne. During the judging some of the horses were sent on a visit to the veterinarian for certificates of soundness, and Ivanhoff, not returning with his licence,

was out of the contest. Lancer is a low horse of some power, but with not the best-formed fore-legs, though he has in other respects a fair fore-hand; however, he is mean behind and a very straggling, wide goer; but, as he is only three years old, he might improve, but never grow into a good one. Angelus, a prize horse at the Great Yorkshire shows, held at York and Thirsk, was loaded with flesh—the fat running off him like butter, in his box. He has not improved since York, where we consider he was placed before several horses much better adapted for getting hunters, as he is anything but true-made or well balanced, his beefy fore-hand being out of all proportion to his hind-quarters. Loaded with lumber, as he is, and not brilliant in action, he came paddling into the ring more like an animated Suffolk or a fat ox than a thoroughbred. General Hesse, though a smaller horse, is much more to our mind, for he walks away well, and though lightish in his middle he is not half a bad one for the purpose; while there is something very grand in old Naseby, with his fine, haughty head, rather dilapidated middle, and rare-formed, oily-going old limbs. He reminded us something of Sir John Barleycorn, and like him has been hunted, carrying a gentleman whose years added to those of Naseby are something over eighty. John Halifax moved well; but his handsome looks smack more of the light charger, park, or harness sire than the hunter; and Rouge Dragon is such a deformity that it astonishes one how he could have escaped the knife. Hurrah has a fair but long top, with wooden, stilty fore-legs; and Cawood, with good shoulders, has a mean and anything but a taking appearance. It will be seen by our summing-up this was not a grand class, although there were four or five very decent-looking horses out of the nine. The best hackney stallion to our mind is a neat thoroughbred when he can be had, and while a horse that could move like Greenford by Ellington, out of Madame Landeau by the Libel, was in the ring, we consider it anything but judgment to have given the prize to the coarse-shouldered Norfolk roadster, Ambition. What mares would the judges put to such a horse with the expectation of getting anything with fashion to carry a gentleman? But these hammering, fussy, flourishing vulgar goers are, we are glad to see, in the course of civilization becoming extinct. The second was the well-known cob-stallion Lucifer, and the third a neat little horse, with limbs that he could move, by the ewe-necked, old savage Footstool, out of Lady Liveden by Oscar. Then again, in the pony stallions, Jack Horner is as vulgar a looking beast as any one would not wish to see in the form of a thick, heapy, cart-like cob, and yet placed before the blood-like King Arthur! and that fashionable little swell, Bobby, from Donnington!

We come on to something far better in the hunters, mares, and geldings, without condition to weight, and a capital class, headed as it is by Captain Heygate's well-known brothers Denmark and Mountain Dew, whose merit is not only in their looks, for they are both tried good ones over a country. But they have not much chance of bringing those hind legs under them, and showing themselves off to advantage to-day, for, though upon the race-course, the going is as slippery as glass. They are on sale we hear, and at so moderate a figure that such a chance does not often happen to those in search of a couple of the right sort, just getting into their prime. However, Mountain Dew has to play second-fiddle to-day to the handsome Lady Derwent, who looks as unlike having done any service as a new hat just out of the tissue-paper and bandbox. We do not hold with this bandbox work, and the terrible trial her ladyship had to undergo before passing the veterinary mill must have told on the nursing and spoiling of a prize nag. We wish the ground had been in going order that we might have seen My Lady have a

spin with Mountain Dew; for till then we shall not be too liberal in our praises, as it struck us she went rather pitchy in her walk, as well as other paces, and the way she "roached" her back at first did not look like pleasant riding. We have had enough of mere show horses—Master of Arts, Voyageur, Beechwood, and so forth. Orangeman by Angelsea, a horse of Mr. Tailby's, with length, good ends, big arms and thighs, who looked and went like a hunter, was much fancied; but there was something, with all this, wanting, for he passeth not the mill. He has the slightest inclination to be back at the knee, and, although the merest trifle out of the line, we would always prefer it the other way. He showed better two seasons back when he ran away with the first prize at the Leicester country show. Of another stamp, immensely business-like, though with the servants' stamp upon them in such company, is Balance-in-Hand, so beautifully put together, strutting about with his baggy breeches, and his stout-looking, short-necked companion Freeny—prize horses at Birmingham, which, with the mealy-coloured bay Thorpe Malsor, have figured at full length in these columns before now. Then another short, compact one, but not with the frame of Balance-in-Hand, but with a dash more blood, is Andover; and, though his white legs are over at knee, he brings the hind ones under in a style that looks like getting out of any difficulty; but with Lord Rosslyn's Gentleman-in-Black, as a hunter, we were not much taken. Rupert, from Rugby, is useful and well-made; and Peach, with more blood, a rather light but nice mare from Nottingham. Then, very hunting-like, is the third prize—Mr. Lovatt's Emperor; Mr. Cooper's chesnut; and Mr. Wood's light-boned mare, with fired hocks, from Market Overton. Mr. Bailey, of Uppingham, sent a coarse, lumbering chesnut—about the only one with nothing hunting-like about him. Good again were the four-year-olds, and among them several that we have noticed during this season. Nugentstown, the first of the four-year-olds at Islington, Tipperary and Shambally, the first and third at Birmingham, were all bowled out by the second-prize four-year-old at Islington and Birmingham, Brigadier—the second being the sour-headed, bad shouldered and slack-jointed Gaylad, a horse passed unnoticed in the lists at Islington. Beyond these were Mr. W. H. Potterton's upstanding black, by Lovett; Mr. J. E. Bennett's neat, good-moving, hunting-like, brown, by Orpheus; and Mr. Gale's Monarch, a prize four year-old, at Oundle, who falls off behind, and stands with his hind legs anything but under him. This is a verdict we don't expect to see endorsed if the same horses meet again. The hunting brood mares were well represented, as among them were Capt. Barlow's Silver Locks, the first-prize mare in this class last year at Bury; Whisky, a good-limbed old mare, and dam of Mountain Dew and Denmark; the grand lengthy-looking Maid of the Heath, with a fine forehead on a short leg; and the hunting-like good shoulder, well put together, though of less substance, Go-a-head, a mare we noticed at Thirsk last year, and who, some thought, ought to have been here first. There were three or four good specimens of hackney brood-mares, and one—Black Fanny—remarkable for her angular frame and extraordinarily drooping abdomen, showing how years and youngsters will change the nattiest of forms, as we have no doubt dark Fanny's has been in her day. British Queen is a neat round square mare; but Gipsy pleased us more, being a very varmint old mare of great character; while Mr. J. N. Beasley's well-known Geraldine was much more to our fancy than the third.

In the hacks were a few neat ones, amongst which was the Thurgarton Rose, *alias* Crisis, that wants a little more depth in her middle; yet why change the name of

so public a performer? The first prize was a vulgar round-shouldered bay; the second a park hack, verging on the light charger in formation, whilst the deep-waisted Lady Flora, the cobby Kegworth, and the showy Birthday, all of Leicester town, had something commendable about them; as two others we had almost omitted—the short, thick, drooping-quartered, quick-stepping Rosabella, a hack of Mr. Hack's, and Mr. Lund's Flora of Leeds. The cob-mares or geldings were chiefly remarkable for The Dean, Lord Roslyn's Ialington prize-cob, the best of the bunch of six a longway, but over height and out of the hunt. Almost as conspicuous was Zingara, one of those flourishing, high-going, dishing trotters that a butcher's boy might be proud of, and who, throwing her legs about "like a daddy long-legs with one foot in a tallow candle," can catch the eyes of the judges directly and get a prize; while neat hacks, like Sir A. G. Haslerigg's grey, are sent empty away. In the ponies, not exceeding fourteen hands, Matchless is a lengthy, well-formed mare, rather light of bone, but a first-rate walker; and the second, the well-known Piccadilly, is, with more substance, really a very nice little hack of fashion. The third was Pretty Seesun, very flash, with her twopenny-concert name and chignon tail.

The class of cocktail stallions to breed hunters from was very wisely abandoned; and the still more cocktail business of proving hunters by jumping was also given up at "the first asking." But nothing can look tamer or work worse than the plan of sending horses out of the ring for a certificate from the Vets, whereby all the pleasure and profit of studying the awards is too often destroyed.

Suffolk as usual was in force in the agricultural classes, but with nothing in numbers like to the armies in red there were marshalled on the flats of Battersea, or on the slopes in the ever memorable drenches of Bury. Still there were a great many of the pick of last year again in the classes, with the customary changing and shifting, making the first last and the last first; but the judging did not satisfy the Suffolk men as did the decisions at Framlingham. In the stallions not qualified to compete as Suffolks we should have gone like an arrow for the Clydesdale, the exceedingly handsome young Lofty, who in symmetry, quality, activity, freedom in the shoulders, and in the placing and formation of his beautiful short hump, is a long way ahead of Honest Tom, the well-known prize three-year-old; making allowance that is for age and the Shire being a bigger and coarser animal. The third, young Sampson, is a very useful horse, while the commended Victor struck us as being all hind-quarters like a Birmingham hansom. Amongst the stallions foaled in 1866, not Suffolks, there were some useful horses the first, Lion, being a very handsome two-year-old, a deep, compact, good-ended, well-set horse; the second, Conqueror, a big raw youngster, that looked like growing into a good one; while the third, Sandy, though coming from the Court, was but an ugly Scot. The highly commended Rutland Hero was a Shire horse, and the light-boned Major a fatal cross, we should say, between Essex and Suffolk, so far as agriculture be concerned, and one more adapted for the town van of some strong active young washerwoman doing a good stroke of business. In the Suffolks foaled before '66, Cupbearer, the four-year-old first at Framlingham in the All-Aged Class and second at Bury in the Three-year-olds, was now placed third; the first being a three-year-old, beaten by the second horse at Framlingham last week, but who beat the second at Bury. This is ringing the changes, and no mistake. The first here has an unpardonable defect, being lighter in his thigh, just below the stifle, than he is at the hock, where it is drawn in as if he had been wearing garters. Harwich Emperor did not face the tribunal. In the Agri-

cultural Mares, Jet, a deep-topped, good-ended, short-limbed active mare, with a remarkably light head and neck for her weight and inches, was first; while the second is a fine-grown mare, with queer forelegs. There was nothing to go for third honours; and in the next class the Suffolk Violet had the three prizes to pick from, Major Maitland had two handsome first and second fillies; but, for good looks, Young Lofty, the black mare Jet, and the iron-grey Lion pleased us most of all "the Agricultural Purposes."

The Leicesters at Leicester would be one of the prime features of the whole show. It is rarely that these sheep have been so generally good, while the competition in all the classes, as estimated even by mere numbers, was capitally sustained. There were but few delicate sheep, but plenty of the best breeding about, as evinced in the clean, lean heads, fine wool, and, it may be emphatically added, the firm touch. Seldom have the Leicesters handled so well, and they proved as handsomely to the eye. Mr. Borton admitted that he had never got together so good a team, more especially of shearing rams, and yet the Barton entries were fairly beaten both for first and second. Col. Inge came back to all his former excellence with a ram of fine size, great breadth, and good style; while the younger Turner and Sanday are well maintaining the repute of their father's flocks. Mr. Turner, jury, was again first for old sheep, with a son of the Bury ram so that he would seem to have quite established his own sort at Alexton; and Mr. G. H. Sanday's sheep looked a deal better done by, despite the hot weather, than they did at Bury. Mr. Borton's yearlings, chiefly by Black-eye, never showed more breeding, one being quite small and pretty, not often characteristics of the Yorkshire Leicester. Of course he had lots of prize sheep in the older class; although his best, here placed second, was nowhere at the last Royal Meeting. A prize sheep of Mr. Creswell's was now unnoticed; and such breeders as Mr. Marris, Mr. Riley, Mr. Stamper, Lord Berners, and Mr. George Turner, could reach no higher than commendations, where almost everything might have been commended. This was more pointedly observable amongst the ewes, where of course the entries were by no means so numerous; but a large majority of the pens received some notice, and the breeding ewes were really admirable illustrations of the Leicester in fair working condition.

Many of the Cotswold ram-breeders still hold off; and the once-imposing array of these grand animals has broken through. But it surely must be detrimental when Mr. Brown, of Marham, with a Norfolk-bred one, and which would have been known, until within this last year or so, as "a Norfolk Long-wool," can again beat the Hill champions, the Gilletts, King Tombs, and Beale Browne; and in these names is included the whole list of exhibitors of Cotswolds. Mr. Tombs certainly came to the rescue amongst the old sheep with his famous 210 gs. ram, bred and bought of Mr. Lane of Broadfield; but another of the Longford rams was disqualified as unfairly shorn; and amongst the ewes Mr. John Gillett was awarded the first prize for one pen, and was disqualified for the other! But, as in other cases, the condemned exhibitors are prepared to prove that all the sheep were shorn on the same day, and protests either have or will be entered accordingly.

"The other long-wools," that is to say, the Lincolns, are rapidly advancing, and made so good a front here both for numbers and merits, that the breeders might surely claim classes of their own. Certainly, from what there was to see at Leicester, if the Oxford, the Hampshire, or even the Cotswolds are entitled to such a recognition, the Lincolns are as justly admissible to the rank of a distinctive breed or variety. There were not only more of them, but they were more uniform in cha-

raeter, while they were unrivalled for wool, and tell well with the butcher. The time was when the Marshalls had it all their own way with the show Lincolns; but they could only win in their turn at Leicester, and Mr. Lynn was without a place. There are other breeders who only require bringing out, and some like Mr. Wright, of Nocton, who are becoming better known as they are more known.

There were no very "leading" sheep amongst the Oxford Downs, and a moderate and useful, but by no means "advertising" entry would be the highest compliment that could be paid them. Mr. Wallis, of Shifford, took all the chief honours, and Mr. Charles Howard could get no higher than a commendation. Mr. Treadwell's second prize old ram is a six-year-old "Brackwell" wearing wonderfully well; and Mr. Treadwell's two pens of ewes were supposed to have done a little too well, for the inspectors disqualified them both; whereupon Mr. Treadwell will call evidence on oath to the contrary. Mr. Henry Overman, as a good second for ewes, still, maintains the merit of his cross, an Oxford like the Marham Cotswold, manufactured in Norfolk, and with which they can successfully encounter the "old original."

"The sensation" of the meeting was over the Southdowns, which the judges took late in the day, so that what with the heat and the amount of competition, this trio looked to have had quite enough of it by the time they were through. Still they did not suffer their work to beat them; for never were awards more heartily approved. Nevertheless, these went in comparatively a new direction to that which has been the order of things of late. Although, to use his own words, Lord Walsingham declined to run for the first heat over his own course in Norfolk, he was now beaten, and easily beaten, in both classes of rams; as certainly the Merton sheep have seldom shown to less advantage. They were many of them loose to the hand, as here and there you come across a sheep with a heavy-hanging Hampshire head, and with little but his size to his credit. The second prize shearling, however, has been hired by his Royal Highness the Prince of Wales, and others purchased to go abroad; but if we are to preserve the true type of the Southdown, it is a nice question whether we should not go more for Lord Sondes' high-bred animals, or even for the still more dainty little "gentlemen" at Audley End. But the happy union of size with blood-like character was hit by Mr. Rigden, whose shearling is as clever a sheep of his sort as has been out for many a long day. He has a good well-coloured head, a muscular neck, a round springing barrel, and a famous hind-quarter, being beautifully let down to his hock. Then, his touch is firm, although for wool and flesh the highly-commended sheep from Hove is as good or even better than the winner. The judges, however, declared that they had no difficulty in finding their first sheep in either class, and but for one deficiency they would have recorded the best old ram as about the best they had ever met with. Of fine size, with a beautiful back and loin, and of admirable quality, this sheep has absolutely no dock, although otherwise so good to meet or follow. He was the prize shearling last year at the Brighton Meeting of the new Southern Counties Association, although with Mr. Rigden's other sheep strangely overlooked at Bury St. Edmunds. Both the shearling and two-shear winner are by the Babraham ram bought by Sir Thomas Lennard for 170 gs., and subsequently let to Mr. Rigden, so that the long price has, after all, been warranted. Lord Walsingham's ewes were really excellent, or, indeed, they could never have got before such good pens as those of Lord Radnor, the Duke of Richmond, Messrs. Heasman, and Sir William Throckmorton. The class might have been

commended, as the general show of Southdowns was very good, with a leaning observable for style and blood, in preference to the sacrifice of such essential points to mere size. The Oxford, Hampshire, or Shropshire is a good useful sheep for roughing it; but, after all, the Oxford and Shropshire owe something to the pure Down, as the Down should certainly never borrow in turn. Of the Hampshires, there was a very short and not very extraordinary show. Mr. Rawlence's ewes were not up to the Bury standard, and his old rams had but two other sheep against them. Amongst the shearlings, the Messrs. Russell, who cultivate this breed in Kent, were placed first with an animal so horribly coarse and bad about his head that it is strange how the judges could ever have passed him. But, then, a heavy lop-ear, a fiddle-pattern face, and a hang-dog expression are said to be essential properties of the Hampshires; although, at most points, Mr. King's second was surely a better sheep. He was handsomer about his head, it is true; but, at the same time, he was more symmetrical in his frame, and smarter in his carriage; and we believe that the judges divided over the award.

There was no sort of stock on the ground that showed so much "the force of circumstances" as the Shropshire sheep. Occasionally you come across a Short-horn whose owner must have gone for "the wooden spoon," or encountered a Suffolk horse that was clearly sent on the chance of his being sold at "some" price or other. But there were so many good Shropshires balanced by so many bad; and, then again, there were so many disqualified, and so many otherwise commendable amongst these outcasts, that one had to sum up with more than customary care. Our own opinion, then, is that the Shropshire made a very strong muster. Casting out the bad and indifferent on the plea of their being handy home, or on the yet more merciful consideration of the Suffolk gentleman whose great hope is that the chestnut will never go back again, there were still more really good young sheep than have been previously got together. These exhibited, moreover, leading characteristics that were pretty generally recognizable by those not engaged in this special business—for a business it is—and our first walk down the lines went to assure us that the Shropshires were being cultivated up to a certain standard of points, with more care and unanimity than has hitherto been observable. Good as were the shearlings at Bury, there were better at Leicester; and the Uffington speckle-faces had now no place. The Messrs. Crane, perhaps, a still more formidable name, were placed first with a very noble, handsome sheep, although, as with Mr. Evans last year, it was said that a better sheep from the same flock was passed over—a point of difference that may be settled at the autumn sales. Mr. Mansell was second with a capital lengthy sheep, good to meet or follow, as better when seen out than in—the true test, after all, of any animal. He was also third with another Maccaroni; and then our catalogue reads like a very labyrinth of commendations and disqualifications, that we shall not care to separate. The entries, however, of shearing rams, reached to upwards of sixty, including, amongst a somewhat curious compound of exhibitors, Lord Willoughby de Broke, Lord Wenlock, Lord Chesham, Mrs. Baker, Mr. Byrd, Mr. Mathews, Mr. Sheldon, Mr. Bradburne, Mr. Henry Smith, Mr. Beach, Mr. Thornton, and Mr. Holland, beyond those we have previously and those we need not name. Mr. Evans' best old sheep was only highly commended at Bury, although, if we remember aright, he afterwards let for more money than either the first or second, and he has gone on capitally since, having plenty of length, size, and style. The second old sheep is bad about his neck; and the third, with a plain head, has a somewhat old-fashioned

character, as, in fact, barring the winner, the rams of any age were nothing extraordinary, and Mr. Holland took the reserve number. But the shearing ewes, like the shearing rams, were capital; Mr. Evans winning with a beautiful sorty pen, wonderfully got up in the way of wool; and Lord Chesham reaching second with a very neat lot, not quite uniform about their heads, but otherwise full of style and quality. If they be not going a little away from the Shropshire type, they were amongst the prettiest sheep in the show. Mr. Coxon's ewes were far better than Messrs. Crane's, by which they stood—and that is saying something, too; while Mr. Yates was disqualified for a pen that must have been noticed had not the inspectors interfered. It is right to say that the third judge, Mr. Randell, was too ill to act, and that Messrs. Horley and Woods took the work upon themselves.

The pigs are nowhere better sorted than they now are on the prize list of the Royal Agricultural Society. The big whites and the small whites, the small blacks, the Berkshires, and the middle breeds have all classes of their own, and the arrangement seems to work very satisfactorily. The Yorkshire big pigs have lost something of their coarseness, and it is significant that the best small white boar was bred in Suffolk, although exhibited by a Manchester man. But both Messrs. Crisp and Sexton have been sending pigs northward of late, where they are pretty sure to improve their quality. The best black boar was of the Fisher Hobbs improved Essex kind, and the next best a black Suffolk; awards that point to the line which the judges are taking. Nothing can be less telling than the mere size of a monster pig, much as he may be fancied in Yorkshire; and for prize stock we need something of an "improved" character. The Berkshires were a good but not a large class; and in fact, in a majority of cases, the competition was not great; but the sample was superior; and pigs that could win at Leicester will be pretty certain to hold their own hereafter, let them travel either North or South.

Well as the show went, the General Meeting on Saturday was one of the most stormy and detrimental that the Council has ever had to encounter. It appears that at the dinner of the Central Chamber of Agriculture, on the preceding evening, Mr. Clare Sewell Read, in returning thanks on behalf of the Royal Agricultural Society, said, in the course of his remarks, that "the Society was not supported by the tenant-farmers in the way he should like to see it, while he must freely admit there was sufficient reason for such support not being accorded. He meant to say the Council was a pocket borough." And, again, he contended "that there was a set of gentlemen on that Council who did all they could, and who spoke whenever they could, against the agricultural interest, and always voted against them. In speaking in the House of Commons in favour of the Cattle Market Bill, or in favour of the Malt-tax repeal, it was very damaging to the little influence he (Mr. Read) had to have a gentleman of the Council of the Royal Agricultural Society getting up and making speeches and voting directly against the agricultural interest. They would scarcely believe that the gentleman who drew up the Report the other day against the Report of the majority of the Malt-tax Committee—a Report which said that the malt-tax was no sort of burthen to the British farmer, and who drew up a Report of the Trade in Animals Committee, which said that there ought to be the same restriction put upon English stock as was placed upon foreign cattle, was a leading member of the Council of the Royal Agricultural Society." It may be right to explain here that the Report recommending the repeal or re-adjustment of the Malt-Tax, and of which we gave the chief points last week, was only carried by the casting vote of the chairman. An opposition Report

was prepared by, as we believe, Mr. Dent, that went to declare "that the tax is easily and cheaply collected, not treading with harshness upon the operations of trade, nor injuriously affecting the retail price of beer to the consumer."—That "the evidence against the tax is generally presented by agriculturists, who complain of any impost upon their produce, as obstructing a judicious course of husbandry, and interfering with their unrestricted use of their own crops, both in supplying beer to their labourers and in feeding cattle and sheep;" but that "the evidence of the corn-dealers, and of the large brewers, and buyers of barley tends to throw doubt on their first objection; and the payment of beer in lieu of wages does not appear to your committee a sufficient reason for removing so important a branch of the revenue."—That "various propositions have been submitted as to the substitution of a beer tax in lieu of the malt duty; but your committee do not incline to look with favour upon the proposal."—That "another suggestion, to levy a licence-duty instead of the Malt-Tax, would obviously be a mere shifting of the present tax, involving considerably more trouble in its collection, and risk to the revenue, without any sufficient advantage;"—and so on.

At the General Meeting Sir George Jenkinson very properly reported the substance of Mr. Sewell Read's remarks upon the previous evening, and this gave the signal for a general attack. The little value of the Journal, the unwarrantable interference of the Journal Committee, the absurd constitution of the Implement Committee, the want of courtesy on the part of the Council, and the system on which the Council is elected, all came in turn to sustain some very severe criticism. Some, indeed, of the leading members of the direction were individually singled out by name. Thus, Mr. Thompson "admired his own mannikin," in other words, the Journal; if Mr. Acland "had his living to get as a writer, no one would think of employing him;" and Colonel Challoner, as the Chairman of the Implement Committee, was ridiculed for some certain description of prizes he still retained on the prize list. It has often been our duty to advert to the management of the Royal Agricultural Society; but never have graver charges been brought than by some of its own members at Leicester on Saturday.

## PRIZE LIST. CART HORSES.

### STALLIONS.

JUDGES.—H. Crosse, Stowmarket.  
J. Steadman, Bognall, Roslin, Edinburgh.  
A. Turnbull, Cresswell, Morpeth.

Stallion, foaled before the 1st of January, 1866 (not qualified to compete as Suffolk).—First prize, £25, W. Welcher, Upwell, Wisbeach (Honest Tom); second of £15, Earl Beauchamp, Madresfield Court, Malvern, Worcestershire (Young Lofy Clydesdale); third of £5, J. Edmondson, Extwistle, Burnley (Young Sampson). Commended: J. Henderson, Horsley-hill, South Shields (Victor).

Stallion, foaled in the year 1866 (not qualified to compete as Suffolk).—First prize, £20, H. Hitchcock, Chittern All-saints, Heytesbury (Lion); second of £10, J. Manning, Wellingborough (Conqueror); third of £5, Her Majesty the Queen, Windsor Castle (Sandy Clydesdale). Highly commended: T. Middleton, Uppingham (Rutland Hero). Commended: R. G. Salmon, Great Clacton Hall, Colchester (Major).

### SUFFOLK.

Stallion foaled before the 1st January, 1866.—First prize, £25, W. Wilson, Baylham Hall, Ipswich (The President); second of £15, T. Crisp, Bentley Abbey, Wokingham Market; third prize of £5, T. Crisp (Cupbearer). Highly commended: M. Biddell, Playford, Ipswich (Punch). Commended: T. Crisp.

Stallion foaled in the year 1866.—First prize, £20, G. D. Badham, Bulmer, Sudbury (Fitz-Emperor); second of £10, W. Wilson, Ipswich; third of £5, L. Rist, Tattingstone (Young Champion).

Agricultural Mare and Foal not qualified to compete as Suffolks.—First prize, £20, W. Tennant, Selby (Jet); second of £10, J. G. Attwater, Britford, Salisbury (Violet).

Mare and Foal.—First prize, £20, S. Wolton, jun., Woodbridge, Suffolk (Violet). No further competition.

Filly, two years old, not qualified to compete as Suffolk.—First prize, £15, R. Maple, Aston-on-Trent; second of £10, T. Baldwin, Tanworth, Hockley Heath, Warwick; third of £5, Her Majesty (Meg Clydesdale).

Suffolk Filly, two years old.—First prize, £15, Major F. M. Wilson, Bury St. Edmund's, Suffolk (Violet); second of £10, Major F. M. Wilson (Bury Empress); third of £5, I. Rist, Ipswich (Blossom). Highly commended: I. Rist (Scot).

### THOROUGHBREDS, HUNTERS, AND HACKS.

JUDGES.—J. Atkins, Brandon, Alnwick.

C. M. Nainby, Barnoldby, Grimsby.

Sir G. T. Wombwell, Newburgh Park, Easingwold.

Thoroughbred Stallion, suitable for getting Hunters.—First prize, £100, Sir G. Cholmley, Bart., Newton Rillington, Yorkshire (Angels); second of £50, W. Gulliver, Banbury (Naseby); third of £10, Earl Spencer, Northampton (General Heese).

Stallions not less than fourteen hands two inches, nor exceeding fifteen hands two inches, suitable for getting Hackneys.—First prize, £25, C. Beart, Downham Market, Norfolk (Ambition); second of £15, F. Barlow, Woodbridge, Suffolk (Lucifer); third of £5, W. King, Stamford.

Stallion not less than sixteen hands, suitable for getting Coach Horses.—No entry.

Pony Stallion under fourteen hands two inches.—First prize, £20, J. Baldock, Bingham, Notts (Little Jack Horner); second of £10, C. Groucock, Wymondham, Norfolk (King Arthur); third of £5, A. Doyle, Abergale, Denbigh (Tramp).

Hunter, mare or gelding, not less than five years old.—First prize, £50, E. Hornby, Ganton, Yorkshire (Lady Derwent); second of £25, Captain E. N. Heygate, Buckland, Leominster (Mountain Dew).

Hunter, mare or gelding, four years old.—First prize, £30, J. B. Booth, Killerby Hall, Catterick (Brigadier); second of £15, J. Drage, Northampton (Gay Lad).

Mare, in foal, or with foal at foot, suitable for breeding Hunters.—First prize, £25, J. Byron, Sleaford, Lincoln (Maid of the Heath); second of £15, Capt. E. N. Heygate (Whiskey); third of £5, J. T. Robinson, Topcliff, Thirak (Go-a-head).

Mare not less than 14 hands one inch, nor exceeding fifteen hands one inch, in foal, or with foal at foot, suitable for breeding Hackneys.—First prize, £30, F. Cook, Thixendale, York (British Queen); second of £10, W. B. Woodroffe, Loughborough, Leicester (Gipsy); third of £5, A. B. Howland, Thame (Paul).

Hackney Mare or Gelding, not exceeding fifteen hands one inch, four years old and upwards.—First prize, £20, A. Hack, Grantham; second of £10, F. Wollaston, Nuneaton, Leicestershire (Eric).

Ob Mare or Gelding, not exceeding fourteen hands one inch, four years old and upwards.—First prize, £20, C. Groucock, Wymondham (Champagne Charley); second of £10, J. Warth, Ely (Zingara).

Pony Mare, not exceeding fourteen hands.—First prize, £15, J. Warth, Ely (Machless); second of £10, F. Barlow, Woodbridge (Piccadilly); third of £5, C. Groucock, Wymondham (Pretty Secusan).

### CATTLE.

#### SHORTHORNS.

JUDGES.—G. Drury, Holker Grange, Lancashire.

T. Hunt, Thornton, Coldstream, N.B.

F. Tallant, Easbourne Priory, Midhurst.

Bull above three years old.—First prize, £25, T. C. Booth, of Warlaby, Northallerton (Commander-in-Chief); second of £15, J. Peel, Knowlton Manor, Clithero (Knight of Knowlton); third of £5, W. Calles, Bodicote House, Banbury (Huntsman). Reserve: G. R. Barclay, Kennil Dunfermline, Fifeshire (Heir of Englishman). Highly commended: J. Lynn, Church Farm, Stroxtun, Grantham (Prizeman); and F. H. Fawkes, Farnley Hall, Otley (Friar Bacon). Commended: J. Pulley, Lower Eaton, Hereford (Royal Buck); and R. Ratcliff, Walton Hall, Burton-on-Trent (Gaylad).

Bull above two and not exceeding three years old.—First prize, £25, W. H. S. Adcock, Farnish, Wellingborough (Baron Geneva); second of £15, Lady Pigot, Branches Park, Newmarket (Charles Le Beau); third of £5, T. E. Pawlett, Beeston, Sandy (Baron Warlaby). Highly commended: H. Aylmer, West Dereham Abbey, Stoke Ferry, Norfolk (General Hopewell). Commended: R. Stratton, Wall's-court, Bristol (James the First).

Yearling Bull, above one and not exceeding two years old. First prize, £25, J. Meadows, Thornville, Wexford, Ireland (Bolivar); second of £15, Lady Pigot (Rosalia); third of £5, T. Walker, Stowell Park, Northleach (The Cotswold Examiner). Highly commended: F. H. Fawkes (Fra Diavolo); and Rev. W. H. Beaver, Pencers-court, Ross, Herefordshire

(Rose Butterfly). Commended: J. Peel (Baron Beust); F. H. Fawkes (Lord Belmore); Earl Radnor (Orkney); and Lord Feversham (Manchester).

Bull Calf, above six and not exceeding twelve months old.—First prize, £10, G. S. Foljambe, Osberton-hall, Notts (Knight of the Bath); second of £5, G. S. Foljambe (Knight of the Crescent). Highly commended: F. H. Fawkes (Lord Montgomery); J. Lynn (Grand Sultan). Commended: Lord Walsingham, Merton-hall, Thetford (Wensleydale).

Cow above three years old.—First prize, £20, T. C. Booth (Lady Fragrant); second of £10, J. How, Broughton, Huntingdon (Jolly Queen); third of £5, Lady Pigot (The Queen of Rosales). Highly commended: R. Tennant, Scarcroft Lodge, Leeds (Miss Farewell); and G. Garne, Othurchill Heath, Chipping Norton (Lady Lucy). Commended: G. S. Foljambe (Cherry Blossom); C. J. Bradshaw, Alstre, Burley-on-the-Hill (Beauty); and Sir W. de Capell Brooke, Bart., Geddington Grange, Kettering, Northampton (Rose of Baby).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, Her Majesty (Alexandra); second of £10, Lady Pigot (The Dame of Rosales); third of £5, Lord Walsingham (Thoughtless). Commended: J. Bailey, North Lodge, Manafield (Juanita 2nd).

Yearling Heifer, above one and not exceeding two years old.—First prize, £15, J. How (Lady Anne); second of £10, T. C. Booth (Patricia); third of £5, G. Garne (Duchess of Towneley). Highly commended: T. C. Booth (Lady Gaiety). Commended: R. Tennant (Rose of York).

Heifer Calf, above six and under twelve months old.—First prize, £10, Lord Penrhyn, Penrhyn Castle, Bangor (Waterloo 27th); second of £5, B. Stratton, Walls Court, Bristol (Ariel). Highly commended: G. S. Foljambe (Flora); and Lord Penrhyn (Waterloo 26th). Commended: W. H. Beaver (Lady Culshaw).

### HEREFORDS.

JUDGES.—S. Anstey, Manabilly Farm, Far Station,

Cornwall.

W. Franklin, jun., Ascott, Wallingford.

H. W. Keary, Bridgnorth.

Bull above three years old.—First prize, £25, T. Rogers, Coxall, Brampton Bryan (Batten-hall); second of £15, J. Williams, St. Mary's, Kingland, Leominster (Sir George); third of £5, J. R. Paramore, Dinedor Court, Dinedor.

Bull above two and not exceeding three years old.—First prize, £25, J. H. Arkwright, Hampton Court, Leominster (Sir Hungerford); second of £15, T. Duckham, Bayaham Court, Ross (Reginald); third of £5, J. Taylor, Stretford Court, Leominster (Challenge).

Yearling Bull, above one and not exceeding two years old.—First prize, £25, W. Tudge, Leintwardine (Brandon); second of £15, Her Majesty (Prince Leopold); third of £5, J. R. Paramour (Chancellor).

Bull Calf, above six and not exceeding twelve months old.—First prize, £10, W. Tudge, Leintwardine (Landseer). No competition.

Cow above three years old.—First prize, £20, J. H. Arkwright (Hampton Beauty); second of £10, Her Majesty (Agnes); third of £5, H. R. Evans, jun., Swanstone Court (Stately 2nd).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, S. Plimley, Shrewsbury; second of £10, J. Prosser, Broadway, Gloucester (White Rose); third of £5, J. Prosser (Carrie).

Yearling Heifers above one and not exceeding two years old.—First prize, £15, J. H. Arkwright; second of £10, Her Majesty (Duchess de Brontë); third of £5, W. Tudge. Highly commended: J. H. Arkwright. Commended: T. Rogers, Coxall, Brampton Bryan (Queen of the Valley).

Heifer Calf, above six and under twelve months old.—First prize, £10, W. Tudge (Silver Star); second of £5, J. Williams, Kingland, Leominster (Flower Girl).

### DEVONS.

JUDGES.—Same as for Herefords.

Bull above three years old.—First prize, £25, G. Turner, Bramford Speke, Exeter (Albert Victor); second of £15, Viscount Falmouth, Tregethnan (Sunflower); third of £5, T. Davy, North Molton, Devon (Duke of Flitton 3rd). Highly commended: J. Bodley, Stockley Pomesoy, Crediton (Lincoln). Commended: W. Farthing, Stovey Court, Bridgewater (Master Ellic); and J. H. Buller, Downe, Crediton.

Bull above two and not exceeding three years old.—First prize, £25, W. Farthing, Stovey Court, Bridgewater (St. Audries). No competition.

Yearling Bull, above one and not exceeding two years old.—First prize, £25, J. A. Smith, Bradford Peveril, Dorchester (Triumph); second of £15, W. Farthing (Master Arthur); third of £5, J. H. Buller, Downe, Crediton. Highly commended: W. Smith, Higher Hoopers, Exeter. Commended: A. Umbers, Leamington (Captain).

Bull Calf, above six and not exceeding twelve months old.

—First prize, £10, W. Farthing (Napier); second of £5, G. Turner (Earl of Leicester).

Cow above three years old.—First prize, £20, J. A. Smith (Daisy); second of £10, W. Smith; third of £5, W. Farthing (Lady). Highly commended: Her Majesty (Rose of Denmark); and J. A. Smith (Curly).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, J. H. Buller; second of £10, O. Hambro, Milton Abbey, Dorset (Mary); third of £5, W. Farthing (Miss Beacie). Highly commended: Her Majesty (Princess Helena); and G. Turner (Lady Mary). Commended: G. Turner (Verbena).

Yearling Heifer, above one and not exceeding two years old.—First prize, £15, W. Smith; second of £10, J. A. Smith (Pancy); third of £5, W. Farthing (Miss Laura).

Heifer Calf, above six and under twelve months old.—First prize, £10, Her Majesty (Rose); second of £5, J. A. Smith (Picture). Highly commended: J. H. Buller. Commended: G. Turner (Lady Agnes).

#### SUSSEX.

Judges.—Same as for Herefords.

Bull above one year old.—First prize, £15, W. Marshall, Cuckfield (Napier). No competition.

Cow above three years old.—First prize, £15, J. and A. Heasman, Angmering, Arundel (Ada).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, J. and A. Heasman (Leicester); second of £10, W. Marshall (Caroline).

#### CHANNEL ISLANDS.

Judges.—L. P. Le Cornu, Trinity Manor, Jersey.

J. Druce, Eynaham, Oxon.  
J. Ellis, Arlington, Guildford.

Bull above one year old.—First prize, £15, C. Pallot, St. Saviour's (Sultan, Jersey); second of £10, P. Gaudin, St. Helier's, Jersey (Clement, Jersey). Commended: C. Pallot (Black-tail, Jersey).

Cow above three years old.—First prize, £15, P. Gaudin, Spring Farm, St. Helier's (Lady Bird, Jersey); second of £10, P. Gaudin (Lady Best, Jersey). Highly commended: P. Gaudin (Brunette); and Lady Berners, Keythorpe Hall, Leicestershire (Fawn). Commended: C. Pallot (Countess).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, C. Pallot (Shorthorn, Jersey); second of £10, P. Gaudin (Camellia, Jersey). Highly commended: P. Gaudin (Fanny, Jersey).

#### OTHER ESTABLISHED BREEDS,

Not including the Shorthorn, Hereford, Devon, Sussex, or Channel Islands breeds.

Judges.—Same as for Channel Islands.

Bull above one year old.—First prize, £15, The Duke of Buckingham and Chandos, of Stowe Park, Buckingham (Conqueror, Longhorn); second of £10, J. H. Burbury, Kenilworth (Longhorn). Highly commended: Lord Sondes, Thetford, Norfolk (Cupid, Norfolk Polled). Commended: R. H. Chapman, Nuneaton (Earl of Derby, Longhorn); and J. B. Tibbits, Kettering, Northampton (Eolipae 2nd, Longhorn).

Cow above three years old.—First prize, £15, R. H. Chapman, Upton (Brindled Beauty, Longhorn); second of £10, J. Godfrey, Wigston Parva (Red Rose, Longhorn). Highly commended: Sir J. H. Crews, Bart., Calke, Derby (Tulip 2nd, Longhorn); and Sir J. H. Crews (Lofty). Commended: P. Wright, Langley Mill, Derbyshire (Magpie, Brittany); and P. Wright (Nightshade, Brittany).

Heifer in-milk or in-calf, not exceeding three years old.—First prize, £15, R. H. Chapman (Rose of Dishley, Longhorn); second of £10, Lord Sondes, Thetford (Cherry 4th, Norfolk Polled). Commended: Lord Sondes (Kate).

#### SHEEP.

##### LEICESTERS.

Judges.—G. Leighton Osgod, by Scarborough.

G. Mann, Scawby, Doncaster.  
T. Twitchell, Willington, Bedford.

Shearling Ram.—First prize, £20, Lt.-Col. Wm. Inge, Thorpe Constantine, Tamworth; second of £10, G. H. Sanday, Holmes Pierpoint; third of £5, J. Borton, Barton House, Malton. Highly commended: G. Turner, jun., Aloxton Hall, Uppingham. Commended: Lt.-Col. Wm. Inge; G. Turner, jun. (3); J. Borton; T. Stamper, Highfield House, Oswaldkirk (3); R. W. Cresswell (3); G. Turner, Sen.

Ram of any other age.—First prize, £20, G. Turner, jun.; second of £10, J. Borton; third of £5, G. H. Sanday. Highly commended: E. Riley, Kipling Cotes Farm, Beverley; J. Borton. Commended: T. Allen, Thurmanston; T. Morris, The Chase, Uleby; G. Turner, Bramford Spoke.

Pen of five Shearling Ewes of the same flock.—First prize, £15, Lt.-Col. Wm. Inge; second of £10, J. Borton; third of £5, Lt.-Col. Wm. Inge. Highly commended: Wm. Brown, High Gate, Holm-on-Spalding Moor; Lord Berners; G. H. Sanday. Commended: T. Morris; G. Riley.

Pen of five Breeding Ewes, which have suckled Lambs until the 1st of June, 1888.—First prize, £15, Lt.-Col. W. Inge; second of £10, W. Brown. Highly commended: Lord Berners, Keythorpe Hall, Tugby; E. Riley.

##### COTSWOLDS.

Judges.—Wm. Bartholomew, Waddington Heath, Lincoln.  
C. Clarke, Scopwick, Stamford.  
R. Lord, Stanton Harcourt, Whitney.

Shearling Ram.—First prize, £20, T. Brown, Marham Hall, Downham Market; second of £10, J. Gillett, Oaklands; third of £5, J. Gillett, Minster Lovell. Highly commended: T. Brown. Commended: T. Brown.

Ram of any other age.—First prize, £20, J. K. Tombs, Langford, Lechlade; second, J. Gillett, Minster Lovell; third, T. Brown, Marham. Highly commended: T. Brown. Commended: T. Brown.

Pen of five Shearling Ewes of the same flock.—First prize, £15, J. Gillett, Minster Lovell; second of £10, T. Brown, Marham; third of £5, J. K. Tombs. Highly commended: T. Brown; J. K. Tombs.

##### LINCOLNS AND OTHER LONGWOOLS.

(Not qualified to compete as Leicesters or Cotswolds).

Judges as for Cotswolds.

Shearling Ram.—First prize, £20, R. Wright, Nooton Heath, Nooton; second of £10, C. Williams, Carlton-le-Moorland; third of £5, W. F. Marshall, Branston, Lincoln. Highly commended: R. Wright; C. Williams.

Ram of any other age.—First prize, £20, Wm. F. Marshall; second of £10, W. F. Marshall. Highly commended: Messrs. Dudding.

Pen of five Shearling Ewes of the same flock.—First prize, £15, T. Cartwright, Dunston Pillar, Dunston; second of £10, J. Pears, Meres, Lincoln; third of £5, R. Wright. Highly commended: T. Cartwright. The class commended.

##### OXFORDSHIRE DOWNS.

Judges.—E. Little, Lanhill, Chippenham.

R. J. Newton, Campfield, Woodstock.  
J. S. Turner, Chyngton, Seaford, Sussex.

Shearling Ram.—First prize, £20, G. Wallis, Old Shifford; second of £10, G. Wallis; third, J. Roberts, Caswell. Highly commended: G. Wallis. Commended: J. Bryan, Southleigh (2).

Ram of any other age.—First prize, £20, G. Wallis; second of £10, J. Treadwell, Upper Windchendon.

Pen of five Shearling Ewes of the same flock.—First prize, £15, G. Wallis; second of £10, H. Overman, Weasenham, Brandon; third of £5, Sir H. W. Dashwood, Bart., Kirtlington Park, Oxfordshire.

##### SOUTH DOWNS.

Judges as for Oxfordshire Downs.

Shearling Ram.—First prize, £20, W. Rigden, Hove, Brighton; second of £10, Lord Walsingham, Merton; third of £5, Lord Walsingham. Highly commended: Lord Walsingham; Duke of Richmond.

Ram of any other age.—First prize, £20, W. Rigden; second of £10, Lord Walsingham; third of £5, Sir Wm. Throckmorton, Buckland. Highly commended: Lord Walsingham. Commended: H. Humphrey, Ashington; the Duke of Richmond, Goodwood.

Pen of five Shearling Ewes of the same flock.—First prize, £15, Lord Walsingham; second of £10, the Earl of Radnor, Coleshill; third of £5, the Duke of Richmond. Highly commended: Sir Wm. Throckmorton. Commended: John and A. Heasman, Augmering, Arundel.

##### HAMPSHIRE AND OTHER SHORT-WOOLED.

(Not qualified to compete as Southdowns or Shropshires).

Judges as for Oxfordshire Downs.

Shearling Ram.—First prize, £20, R. and J. Russell, Horton Kirby, Dartford, Kent; second of £10, S. King, Bockhampton, Lambourn; third, R. Coles, Middleton, Norton Bavant, Warminster. Highly commended: J. Rawlence, Bullbridge, Salisbury; S. King.

Ram of any other age.—First prize, £20, J. Rawlence; second of £10, J. Rawlence; third of £5, R. Coles.

Pen of five Shearling Ewes of the same flock.—First prize, £15, J. Rawlence; second of £10, J. Rawlence.

##### SHROPSHIRE.

Judges.—T. Horley, jun., The Fosse, Leamington.

J. Woods, Clipstone, Notts.

Shearling Ram.—First prize, £20, Jas. and Ed. Crane, Shrawardine; second of £10, T. Mansell, Adcott; third of £5, T. Mansell. Highly commended: G. Griffiths. Commended: S. Griffiths; H. Smith (2); T. Mansell.

Ram of any other age.—First prize, £20, J. Evans, Uffington, Shrawbury; second of £10, J. and E. Crane, Shrawardine, Shrawbury; third of £5, C. Byard, Littywood, Stafford. Highly commended: E. Holland, M.P., Dumbleton; Lord Penrhyn; T. Jones, Malpas; Mrs. Baker; T. Horton.

Pen of five Shearling Ewes of the same flock.—First prize, £15, J. Evans; second of £10, Lord Chesham, Ladmer, Chesham; third of £5, J. Coxon, Freeford Farm, Lichfield. Highly commended: J. Beach, The Hattens, Brewood; J. and E. Crane. Commended: Lord Chesham; Lord Wenlock; T. Horton; E. Smith.

### P I G S.

JUDGES.—S. Druce, Rynaham, Oxon.

A. Edmonds, Longworth, Faringdon.  
J. B. Slater, Cammeringham, Lincoln.

Boar of a large white breed.—First prize, £10, R. E. Duckering, Northorpe, Kirton Lindsay (Victor 2nd); second of £5, J. and F. Howard, Britannia Farm, Bedford (Victor). Highly commended: W. Hardley, Larkton Hall, Malpas (Cheshire Lad).

Boar of a small white breed.—First prize, £10, Peter Eden, Cross Lane, Salford, Manchester (Lord Nelson); second of £5, W. Hutton, Addingham, Leeds, Yorkshire. Highly commended: T. Atherton, Chapel House, Speke, Liverpool.

Boar of small black breed.—First prize, £10, G. Turner, jun., Alexton (Improved Essex); second of £5, Rev. W. H. Beavor, Pencairn Court, Ross (Black Prince 4th). Highly commended: W. Hemming, Coldcott, Moreton-in-the-Marsh, Gloucestershire (Master M. Thomas).

Boars of the Berkshire breed.—First prize, £10, J. Smith, Henley-in-Arden (Young Punch); second of £5, R. E. Swanwick, Royal Agricultural College Farm, Cirencester (Othello). Highly commended: H. Humfrey, Kingstone Farm, Shrivensham.

Boar of a breed not eligible for the preceding classes.—First prize, £10, R. E. Duckering, Northorpe (Comet); second of £5, Peter Eden (King Lear 2nd). Highly commended: W. Hutton (King of the West).

Breeding Sow of a large white breed.—First prize, £10, Peter Eden (Lucy); second of £5, R. E. Duckering (Countess of Leicester). Highly commended: J. and F. Howard (Miss Kate).

Breeding Sow of a small white breed.—First prize, £10, W. Hutton; second of £5, Peter Eden (Violet). Highly commended: R. E. Duckering (Lily); T. Atherton.

Breeding Sow of a small black breed.—First prize, £10, T. Crisp, Butley Abbey; second of £5, T. Atherton, Chapel House, Speke (Formosa).

Breeding sow of the Berkshire breed.—First prize, £10, Sir W. Throckmorton (Queen); second of £5, T. Crisp. Highly commended: A. Stewart; R. Swanwick.

Breeding Sow of a breed not eligible for the preceding classes.—First prize, £10, Peter Eden (Queen of Trumps); second of £5, R. E. Duckering (Primrose). Highly commended: W. Hutton.

Pen of three Breeding Sow Pigs of a large white breed of the same litter, above four and under eight months old.—First prize, £10, M. Walker, Stockley Park (Tulip, Snowdrop, and Crocus); second of £5, R. E. Duckering (Rose, Shamrock, and Thistle). Highly commended: G. Chapman, Seasmere, Yorkshire.

Pen of three breeding Sow Pigs of a small white breed of the same litter, above four and under eight months old.—First prize, £10, Earl of Radnor; second of £5, H. Aylmer, West Dereham Abbey, Stoke Ferry, Norfolk. Highly commended: Lord Wenlock, Eborick Park, York.

Pen of three breeding Sow Pigs of a small black breed of the same litter, above four and under eight months old.—First prize, £10; second, £5. No entry.

Pen of three breeding Sow Pigs of the Berkshire breed of the same litter, above four and under eight months old.—First prize, £10, J. Smith, Henley-in-Arden; second of £5, H. Humfrey (A. B. C). Highly commended: H. Humfrey, W. Yells, and R. Swanwick.

Pen of three breeding Sow Pigs of a breed not eligible for the preceding classes, of the same litter, above four and under eight months old.—First prize, £10, R. E. Duckering ("Faith," "Hope," and "Charity"); second of £5, G. Chapman, Seasmere, Yorkshire.

### SHEEP-SHEARING INSPECTORS—

H. Bone, Ringwood, Hants.  
J. H. Workman, Rydon, Pembrokeshire.

### VETERINARY INSPECTORS—

Professor Symonds, London (Cattle).  
Professor Varnell, Yarmouth (Horses.)

### ASSISTANT INSPECTOR—

R. L. Hunt, Birmingham.

### W O O L.

JUDGES.—W. Agar, Leicester.  
W. H. Ellis, Leicester.

Six Longwoolled Hogg Fleeces.—First Prize, £10, J. Bowles, Leicester (Leicesters); second of £3, C. Barrowby, Balder, Thirsk, Yorkshire (Leicesters). Commended: O. Bosworth, Dishley, Loughborough (Leicesters).

### B U T T E R.

JUDGES.—H. E. Emberlin, The Hermitage, Oadby, Leicester.  
H. Stches, Derby.

Six pounds of Fresh Butter in one pound lumps.—First prize, £5, Agricultural Colony, Coalver, Leicester; second, Rev. George W. Stratton, Aylestone Rectory, Leicester.

### C H E E S E.

JUDGES as for Butter.

Six Cheeses, exceeding 45 pounds each.—First prize, £10, F. Spencer, Colbrook Magna, Lutterworth; second of £5, W. N. Barry, Stokes Golding, Hinckley; third of £3, Tom Cattell, Bitteswell Firs, Lutterworth.

Six Cheeses, exceeding 35 pounds each, but not more than 45 pounds.—First prize, £10, S. Wykes, Ashton Flamville, Hinckley; second of £7, W. Trivett, Market Bosworth; third of £3, Wm. Nuttall, Oroxton.

Six Cheeses, not exceeding 35 pounds each.—First prize, £10, W. Ward, Nuneston; second of £7, S. C. Pilgrim, Out Woods, Burbage, Hinckley; third of £3, John Harding, Attarnton.

Best Entry in the above classes.—Prize, £15.

To the dairymaid or servant who manufactured the best dairy.—Prize, £15.

Six Stilton Cheeses.—First prize, £10, E. Peel Smith, New Parks, Leicester; second of £7, T. M. Evans and John Stafford, Leicester; third of £3, W. Stannage, Melton Mowbray.

### THE IMPLEMENT TRIALS

In its wanderings throughout England the Royal Society has this year found a brief resting-place at Leicester; if that indeed can be called brief which involves a longer sojourn than has been the wont of the Society. For it so happens, and happens well, that the period during which the trials have to be carried out has been lengthened, so that the actual time over which the Show will extend will not be far off, if not indeed quite, ten days. This lengthening of the period of trial is a move in the right direction, and a "move" in its strictest acceptance. Hours will be given to labours to which minutes were allotted in times gone by; and *gradus par gradus* is, perhaps, after all, the best way to proceed in reforms. Let us then, with such a motto in view, begin to detail "step by step" the work of the week of trial this day, July 9th, inaugurated, and endeavour as clearly, yet as concisely as possible, to give a *vidimus* of what is done or to be done. Misled by the announcement that the trial field was only half-a-mile from the showyard, and but a short distance from the town, we wended our way to the fields, and it was only when we got beyond human, or we should say horse aid, in the shape of cabs, that we found, as one often finds in the world, that "Hope's aye a gay deceiver." The worst of it was not the walk thus involved, although under a sweltering sun and over dusty roads that was bad enough; but the difficulty to find out where the trial-fields were? Some thought they were to the right, some that they were to the left, some straight on; so this seeming to us the most feasible thing to do, we did go straight on, till gladly hailing a return cab, we were taken at once to the promised land.

Arrived at the trial-fields, we had "all the world before us where to choose"—a world comprised within the limits of a no less surface of trial-ground than 180 acres. The choice might have been difficult, where to begin, with a number of claimants for notice pressing upon us. But we have no difficulty. As in a general company "place to the ladies" in every thing is the watchword of a gentleman, so with us, in view of its time-honoured claims, "place to the ploughs" dictates our choice of a subject to start with. The plough trials were carried on in a large well-placed field to the right of that in which the greater number of steam cultivators were placed; and they began

with the *General Purpose Ploughs*, the judges being Messrs. Hipwell, Wheateley, and Bond, for the prizes for which eleven competitors entered. We name these in the order of the plots they obtained to work upon. No. 1 was occupied by Lewis, of the Salopian Iron Works, Shrewsbury, Salop. This was fitted with two wheels, skim coulter, and cast breast. No. 2 was occupied by Page and Co., of Victoria Iron Works, Bedford, and was also provided with two wheels and a cast-steel breast. No. 3 was occupied by Hitherly, of Thrussington, Leicester. No. 4 was occupied by Vickers, Snowden, and Morris, of Doncaster, Yorkshire; this was provided with a skim coulter and steel breast. Plot No. 5 was taken up by Boby, of Bury St. Edmunds, with a plough, with his oval-sectioned beam and patent wheels. No. 6 was taken up by the Howards, of Britannia Ironworks, Bedford; and No. 7 was occupied by Ball and Son, of Rothwell, Kettering, Northamptonshire. No. 8 was occupied by Cooke and Co. of Lincoln; No. 9, by Ransomes and Sims, of Orwell Works, Ipswich; No. 10, by Beadmore, of Woodhouse Eaves, Loughborough, Leicestershire; and No. 11, by Hornsby and Sons, of Grantham.

To each competitor a width of twenty-one feet was given to plough, marked off at the ends with stakes numbering the plot. After opening up the plot with a furrow to the right, and another on the left, abutting upon the plot next in position, and taking three turns, each competitor was to begin the regular work of the competition by taking four turns with a furrow six inches in depth, then four with a seven-and-a-half-inch furrow, and to finish off with a nine-inch furrow. When fairly set to work under these conditions, the trial field here was by far the most interesting of the day; rendered all the more so by the business-like order which characterized the whole proceedings, and which enabled those who watched the work to do their office with comfort and certainty of obtaining accurate results. The field was of good breadth, so that the ploughs had bouts of fairish lengths to "show their paces in," to quote for the nonce a sporting phrase. The soil was heavy—a good wheat soil of fair average quality, although in many places unequal. As may be easily supposed, the long-continued drought made the land by no means in that fine condition in which the work of a plough, and how it turns over its furrow slice, is best shown. Still the work done was, on the whole, excellent, and in some instances very superior. Without prejudice, as the lawyers say, we may thus early state our belief that the prizes will be found to rest between the three magnates of the plough world—the Howards, the Hornsby, and the Ransomes, and in all probability between the first and the last-named of these. Our own opinion so far is in favour of the work done by the Howards, which, in many respects, taking all the circumstances into account, may be classed as a very fine performance indeed; although we do not hesitate to say that the work of one or two ploughs, at some parts of their "bouts," came pretty closely up to that done by those makers more prominently mentioned. The immense advantage which the "crack" men have in such a competition over others is the admirable discipline and management which characterise the work of their respective staffs. One can see at a glance that every detail has been by them attended to, that something in and about the group tells at once that all its members are doing their very best, and mean to win if they possibly can. The very horses are part and parcel of this determination, and they show also the advantages of careful discipline and attention in the minutest details. With arrangements such as those alluded to, it is not to be wondered at that other competitors who have not these favours, at least in such perfection, should really work under a disadvantage. Some have only the merits of their implements to fall back upon; not possessing the best

means by which the implement can be worked. Thus, one of the competitors—Messrs. Vickers, Snowden, and Morris, of Doncaster—had to retire from the competition on account of their having the misfortune to have a pair of restive horses. Now, the horses of Howard, for instance, would as soon think of flying in the air as being restive in the trial field; a glance at them is quite enough to satisfy one that they know what their work is, and that they mean to do it. So steady is their pull, that under a dynamometer their draught would be found to vary within exceedingly narrow limits.

Having mentioned Vickers, Snowden, and Morris as labouring under a misfortune which they could not at the time avoid, it is only fair to them to state that this, and this alone, was the cause of their giving up the trial; it is due to them to state this, as some other idea may have taken possession of the public who were witnessing the works. And we may as well name here that this firm have introduced an innovation, or rather we should say gone back to an old practice in the construction of the plough, namely, the use of timber. This is, however, confined only to the stilts or handles, and has for its aim the doing away with the objections which many have to iron stilts, namely, their elasticity, and the difficulty there is with them to provide for the strains of heavy work. We are quite aware that this view of the superiority of timber over iron stilts is not held by all—we may say not by many; still it is a suggestive circumstance that with ordinary farm ploughmen, wooden handles are in a great number of instances preferred to iron. There is much to be said on both sides of the question, and we shall be glad to know what the judges have to offer on it?

All the ploughs tried in this class were wheel ploughs—a fact which a general spectator might or might not have taken as evidence of the superiority of this form over the swing plough, or at all events as evidence that wheel ploughs are in greater favour amongst farmers than the swing; but the swing ploughs are still held in high estimation by many, and for some classes of soils they are the only ploughs which can do good work—at least the kind of work required. The swing ploughs were tried on the Friday. On looking at those ploughs doing their work, under by no means the most favourable circumstances, and doing it with a precision and a general accuracy of results, one could not help feeling gratified at the high position which this branch of agricultural mechanism has reached; and one which has been reached by the combined influence of the prize system, and the high mechanical skill, the business-like energy, and the lavish outlay of the makers.

For the light-land ploughs, we found the following competing: (14) Cooke, of Lincoln; (18) Snowden, Vickers, and Morris, Doncaster; (22) Boby, Bury St. Edmunds; (17) Hunt and Pickering, Leicester; (16) Hornsby and Sons, Grantham; (10) Howards, Bedford; (19-20) Ball and Son, of Rothwell, Kettering (two entries); (21) Ransomes and Sims, Ipswich. The work done in this class was nearly as good, if not quite so, as the general-purpose-plough trial. That of the Messrs. Howard was thought specially good by many authorities, although a very close comparison of that done by the Messrs. Ransomes and Sims with that done by the Messrs. Howard inclined us to give the palm in favour of the Messrs. Ransomes. As the work of both lies, the judges will have something to do in deciding between the claims of these two magnates; for it is clear to our mind that the prize lies at present between them. But it was a misnomer to call this a trial of light-land ploughs, for the simple reason that it was not light land on which they worked. True, they were ploughs designed for light

land; but that did not make the trials light-land-plough trials. We look, therefore, upon this trial as to a certain extent practically useless—as useless as would be the trial of a machine with cotton as the medium upon which it operated, in place of silk for which it was designed. In a properly-arranged trial, each thing must be compatible with the other, or, to quote somewhat ludicrous, but apt enough phrase in a “concatenation accordingly.”

After the ploughs, we take up the cultivators—the harrows, clodcrushers, and roller trials coming in at a later date. The judges of these departments were Mr. Chambers, Mr. Sherborn, and Mr. Roberts; and hard work they had of it, for a more unpromising field was probably never put before a lot of competitors, who, many of them, must have inwardly felt that it was “no go,” as “no go” assuredly it was, for more than one of them. Many were the attempts made: some were placed completely *hors de combat* by breakage or other mishap; while but two, or—shall we say?—three, made out their bout; but of these three, one did remarkably good work, tearing up and smashing up the soil in fine steady style, and leaving a remarkably level sole. We have long maintained that in certain departments of agricultural mechanism special arrangements or contrivances must be made, to meet special circumstances; and the trials in this field, where the cultivators were at work, more and more convinced us of the truth of this. We had only to look at the soil, and see what a task it was to break it up—like ploughing a street—then to walk along the row of competing implements, to be able at once to point out which had no chance; and, in the face of which, the destiny of failure was plainly written. Not a high degree of mechanical knowledge was necessary to point this out; and in view of it, however much we might admire the pluck of those who did compete under what we knew at once to be most adverse circumstances, we did certainly feel that if we had been in their places we should not have thought of pluck, but of prudence: declining to compete was less of a loss to them than competing only to fail. Out of the entry only two, we may say, did their lots fairly out; and, of these two, one was the cultivation of Mr. Clay, the other that of Mr. Bentall: while the superiority of the work of the latter is that to which we have referred. So far as we saw, the work done by Bentall was the work of the day. In this class Comstock's Rotary Spader competed, and was tried; but it would have been better for the interests of the inventor had the trial on such a soil and under such circumstances been declined. The machine was far too light for the peculiarly trying work it attempted to perform; and it is a question whether it is really fitted for heavy land. The following were the competitors in this class: Sherburn, Clay of Wakefield, Coleman of Chelmsford, Ball of Rugby, Bentall of Maldon, Underhill of Newport, Salop, Hunt and Pickering of Leicester, Coleman of Northampton, and Beadmore of Loughborough.

Passing now from the field in which the cultivators by horse-power have shown in more instances than one how the work is *not* to be done, to that in which the steam cultivators are at work, we see at once that we are in possession of a power which places a wide range of work within the reach of the farmer. Taking the main field, Fowler of Leeds shows a remarkable collection of steam cultivating apparatus, remarkable alike for the number of appliances adapted for almost every kind of work connected with the preparation of the soil for crops, and also noticeable for the costliness of the whole. There are upwards of three hundred tons of machinery exhibited by this firm. They exhibit two engines of twenty-horse power, two of twelve, four of ten, and one

of eight. The twenty-horse power engines are remarkable for displaying to the fullest possible extent the use of steel in their construction—a material of only comparatively recent introduction, but which bids fair to bring about, if it has not already brought about, where used, quite a new era in machine construction, in which the maximum of strength will be obtained with the minimum of weight and, by consequence, of bulk—a fine combination, in short, of lightness and strength. The Fowlers have at work four different kinds of apparatus. The one working this morning was on the direct-action principle, which, the Messrs. Fowler uphold as the best. In this, two engines (ten-horse power each) are placed on opposite sides of the field, and are provided with winding-drums, which take up and pay out alternately the steel rope attached to the implement. The winding-drums work at and give out a steady pull at any angle; and the ease with which the advance is made at the end of each bout is not the only practically good feature connected with the system. The engine works either a five-tined cultivator for deep work at a slow speed, or a seven-tined cultivator for lighter work at a higher speed. Both these were tried this morning, the five-tined cultivator working nearly an acre in the hour, inclusive of setting down, the depth being nine inches and the breadth four feet ten inches, the width between the tines being eleven inches. The depth to which the seven-tined cultivator was worked was only eight inches, in consequence of the extreme hardness of the soil. At some parts, indeed, it was more like breaking-up a hard road or street than farm land. But such as it was, the work done was something extraordinary, and gave ample evidence of the immense advantage of steam power, well applied, in the cultivation of land.

The Messrs. Fowler have also a 14-horse power engine, with their patent clip drum attached, the system being still the direct action; but the self-moving anchor being placed on the opposite headland. This works a fire-branched plough, or a seven-tined cultivator. This apparatus was fixed to work (Saturday the 11th). They also exhibit two engines of 10-horse power each, with double-winding drums. The implements work to and fro between the engines, one of which is placed on one headland, the other on the opposite, each implement, taking only half the field, both meeting in the centre. They also have two splendid engines of 20-horse power each, with single-winding drums; the peculiarity of these is that they are arranged to work at two speeds—the slow speed with great draught, the quick speed with lighter draught. These engines are going to Louisiana, in America, for cultivating sugar plantations. The steel engine exhibited has this peculiarity, that the winding drum is placed behind the engine. The Messrs. Fowler also exhibit a new cultivator, which takes the great width of 15 feet; this is made in three sections or gangs, to allow the implement to accommodate itself to the inequalities of the ground, and an arrangement is adopted by which the tines are lifted up by the engine. A large harrow is also exhibited.

The other exhibitors in this class are the Messrs. Howard of Bedford; Hayes, of Stony Stratford, who works a Smith's cultivator; Tasker, of Andover, who also works a Smith's cultivator; Aveling and Porter, of Rochester, who work a Fowler's balance cultivator, on the round-about system. Of the apparatus of these exhibitors and of the work done we shall give a full description hereafter.

In the horse-plough field, the general purpose and the light land swing ploughs were tried in the morning and afternoon; and in both classes there was some excellent work done. In the general purpose swing ploughs the

competitors were, with the number of the plots, as follows: 27, Cooke and Co. of Lincoln; 26, Boby of Bury St. Edmunds; 25, Ransomes and Sims of Ipswich; 23, Ball and Son of Rothwell; 28, Howards of Bedford; 29, Hornsby of Grantham. These ploughs had to take three "bouts" to get a depth of 6 inches; then to take four bouts at 6½; four bouts at 7 inches; and finish off with 9-inch depth. The competitors and the number of the plots of the light land swing ploughs were as follows: 30, Ransomes and Sims; 31, Hornsby; 32, Howard; 33, Ball; 34, Cooke. These ploughs had to take three bouts to get depth, six at 5 inches, and to finish off at 6 inches. We may here again express our approval of the arrangements made by the stewards and judges of the trial-fields, so far as the ploughs were concerned; everywhere there was evidence of the directing minds of men who knew what their work was, and how to do it. We give this good word with the greater pleasure as on former occasions it has not been altogether deserved.

The trials of the deep-land wheel-ploughs took place in the afternoon of Friday, for which the following were the entries, with the number of their plots: (58) Howard, of Bedford; (59) Ransomes, of Ipswich; (60) Ball and Son, of Kettering; (61) Cook and Co., of Lincoln; (62) Hornsby, of Grantham. The conditions were that each plough was to get first into depth, then to take five bouts at ten inches, and to finish off with a depth of twelve inches. Due regard to the "propriety of things" compels us to record our opinion of this trial, that it was neither more nor less than an exhibition, if not of positive cruelty to animals, certainly of a lamentable want of consideration for them, to say nothing of that of the men employed in working the ploughs. Four horses were allowed; but the soil to be worked was honestly beyond all horse-power. It was work for the steam-engine, with its iron muscles and untiring strength; and it is impossible for anyone who loves horse-flesh to record this trial in any other way than we now record it. The clods moved in many instances exceeded in bulk, far exceeded in weight, those torn up from the iron-bound soil in the steam-cultivated field close by. We would strongly advise the exhibitors on one or two plots we wot of, to take home or get photographed some of the clods turned up, especially in one plot not twenty yards from the end, and not far from if not quite at the top. We measured one which showed a full depth of 12 inches, and would have been a good load for the Irish brick-carrier and his hod. And then, after all this terrible expenditure of muscle and will, both on the part of man and horse, the question at once came up, *Cui bono?* What practically good result to the farmer came of it? Truly not much. Certainly it showed well what horses could do in pulling through such a *bricky* soil—that's the word, nothing else—and how well-made the ploughs were; and that is all that could be said of it. It would be quite invidious to give here any critical notice of the work done: the praise due to all is that they did it at all!

At four o'clock the land rollers were put on for competition on the land ploughed by deep ploughs on Friday: all working across the furrows, and all thus getting a fair share of the work to be done in the way of some rare and heavy clods. Many here, again, were far too light, and we believe that the chances of the prize will be found to lie between two well-known makers. The competitors were as follows: (1) Hunt and Pickering of Leicester, (2) The Beverley Iron Company, (3) Crosskill and Sons of Beverley, (4) Lewis of Shrewsbury, (5) Boby of Bury St. Edmunds, (6) Amies, Barford, and Co. (2 entries), (7) Holmes and

Son of Norwich, (8) Page and Co. of Bedford, (9) Woods, Cockedge, and Co. On Monday a selected trial of clod-crushers will take place, these being taken from the previous competition:—(1) The Beverley Iron Company, (2) Crosskill of Beverley, (3) Cambridge of Bristol, and (4) Amies, Barford, and Co. Selected trials also of the ploughs will come off on Monday—the general-purpose ploughs, the light-land and the deep ploughs (wheel), as also the swing ploughs; and on Tuesday dynamometer trials of various implements are expected to come on.

On the piece of field broken up by the steam-worked cultivator of Messrs. Howard—and wonderfully well broken up it was—the clod-crushers were put to work on the afternoon of Friday. Some dissatisfaction was experienced at their being ordered on here, in place of the horse-ploughed field above—and with some reason too, as the horse-ploughed land was the most fitting for horse-worked clod-crusher to work upon. From what we have said of the cultivation of soil generally, and especially of the huge clods turned up by steam power, it will be felt that one might as well have attempted to "glean after an Irish reaper" as to do any good in reducing such clods to the condition desiderated with some of the implements employed. The majority were too light for such heavy work, and went dancing over the rough surface like cockboats in a sea with nasty cross waves on. Many also, which had weight, smoothed the surface over only, and did not break up the clods which lay beneath. The work of clod-crushers requires to be sharply looked after, as the work here will doubtless be by the judges—the same as already named for the cultivators; for a good surface, as stated above, is often made by simply abrading the tops of the clods, or by shoving some of them bodily along till they meet a depression, or hollow, into which they are crushed; while at the same time the bodies, or bulks, of the clods remain unbroken. The condition of the ground certainly afforded an excellent opportunity to show what could be done, as well as what could not be done, by an implement in this class. The following were the competitors: (1.) Cambridge and Co., of Bristol; (2.) The Beverley Iron and Waggon Company, Beverley; (3.) Woods, Cockedge, and Co., of Stowmarket, Suffolk; (4.) Barford and Co., of Peterborough; (5.) Crosskill and Son, Beverley; (6.) Ball and Son, of Kettering, Northampton; (7.) Ashby and Jeffrey, of Stamford (Paterson's patent); (8.) Hunt and Pickering, of Leicester; (9.) Coultas, of Spittlegate, Grantham; (10.) Lewis, of Shrewsbury, Salop; (11.) The Reading Iron Company; (12.) Boby, of Bury, St. Edmunds.

The subsoil ploughs began to be tried on the forenoon of Saturday, and were continued throughout the afternoon. The following is the list of competitors for this class, with the number of the plots or the order of their working, for all did not go in at once, as in the other trials. (1) Messrs. Ransome and Sims, of Ipswich; (2) Messrs. Hornsby, of Grantham; (3) Messrs. Coleman and Morton, Chelmsford; (4) Messrs. Ransome and Sims (2nd entry); (5) Messrs. Howard, of Bedford; (6) the Reading Iron Co.; (7) Mellard, of Rugeley; (8) Messrs. Howard, of Bedford (2nd entry); (9) Bentall, of Malden, Essex; (10) Messrs. Hunt and Pickering, of Leicester. Each plough was to get the depth in one round, and then to take one at 6 inches and the other at 7 inches. These depths were of course below the sole of the work of the ordinary plough which ran over the ground in the first instance, thus giving ultimately a depth of 13 inches. All the ultimate depths were to be measured from the surface. Several of the ploughs exceeded the stated depth, some going to a depth of fifteen inches.

The harrows were also tried on Saturday, on the ground ploughed by the general-purpose and light-land ploughs on the days previous. We say "tried," but we can scarcely dignify what was done with the title of "a trial," as nearly every practical man present will agree with us. The competitors for the "drag" were: (1) The Canadian Working Company; (2) Messrs. Larkworthy and Co., of Worcester; (3) Page, of Bedford; (4) Messrs. Howard, of Bedford; (5) Love, of Northampton; (6) Love, second entry; (7) Johnson, of Leicester; Bentall, of Malden; Cooke and Co., of Leicester. We shall return to this class, and meanwhile may proceed to note that the special feature of Saturday's work was the trials of the steam cultivating apparatus. These were carried on in a field excellently adapted for the purpose, and the competitors were as follows, with the number of the plots they drew: (1) Messrs. Aveling and Porter, of Rochester; (2) Messrs. Howard, of Bedford; (3) Messrs. Tasker, of Andover; (4) Messrs. Fowler and Co., of Leeds; (5) Mr. Hayes, of Stoney Stratford; (6) Messrs. Fowler and Co., of Leeds (second entry). Numbers 1, 2, and 4 began working first, and off their plots before the work was resumed by the Judges after luncheon. Nos. 3, 6, and 5 entered the field after luncheon.

No. 1, Aveling and Porter's apparatus, was on the roundabout system, working one of Fowler's cultivators, and with one of their well-known traction-engines as the moving power. No. 2, Messrs. Howard's, was also upon the roundabout system, working their own cultivator, and the engine made by Messrs. Clayton, Shuttleworth, and Co., of Lincoln. No. 3, Messrs. Fowler's clip-drum engine and self-moving anchor. All the exhibitors had to remove their apparatus from the field in which they were placed to the field in which they were worked, and to set them in the field ready for starting. All the time taken for this was marked. No. 1 (Aveling's) left the field at 9.40, entered the trial-field 9.45, and commenced work at 10.27. No. 2 (Howard's) left the field at 9.45, entered the trial-field at 10.20, and commenced work at 10.40. No. 3 (Fowler's) left the field at 10.15, entered the trial-field at 10.20, and commenced working at 10.40. The length of the plot of No. 1 (Aveling) was 278 yards and the breadth 23, and they finished the surface contained in this space at 15 minutes past one o'clock. The length of the plot No. 2 (Howard's) was 250 yards and breadth 43, and it was finished at 3 minutes past one. The length of the plot No. 3 (Fowler's) was 162 yards and the breadth 41, and the whole was finished 59½ minutes past 12. We shall in our next give the results of the trials of the other competitors.

We are glad to be able to add the last work of this day, when the relative merits of the respective apparatus were tested by the weight per square yard of soil lifted by each, and which tests we here tabulate:—

NO. OF PLOT.	NAME OF EXHIBITOR.	WEIGHT. st. lbs.
1.	Aveling and Porter, Rochester .....	29 4
2	J. & F. Howard, Bedford.....	30 6
3	Tasker, Andover .....	22 4
4	Fowler, Leeds .....	33 5
5	Hayes, Stoney Stratford .....	13 0½

Messrs. Aveling and Porter worked a Fowler's cultivator; Hayes and Messrs. Tasker a Woolston cultivator; and the Messrs. Howard and Fowler their own special implements.

Of implements there are 340 stands against 282 last year at Bury St. Edmunds; the number of entries being 6,869. The number of implement sheds is 86, 38 of these being 300 feet long each by 90 feet wide; the remainder 200

feet long. There will be in addition eight sheds for seeds and models 160 feet long by 13 feet wide, and the machinery in motion in two sheds 1,050 feet long by 20 to 25 feet wide.

Amongst the steam-cultivating apparatus set to work on the afternoon of Saturday was Fowler's No. 6, Double Winding Drum Apparatus, No. 8, being one of the second lot which entered the field—the three being No. 4, Fowler's Clip-drum and Self-moving Anchor; No. 2, Tasker's, of Andover; and No. 5, Hayes, of Stoney Stratford—both working a Smith's of Woolston cultivator. Hayes took up so much time in setting down that by the time when the day's work of the other competitors was over, he had scarcely commenced; and what he had done was anything but satisfactory. However, on the Monday morning he returned again to his plot, and was, when we were at the field, doing excellent work. The form of windlass which Hayes has invented, presents many features worthy of special notice. Let us here gather up such facts and suggestions as have been brought out by the trials of steam-cultivating apparatus on Saturday. As to the quality of the work, looking at it as it lies, there will be of course divided opinions, but with the decision of the judges resting between the work of the Messrs. Howard and the Messrs. Fowler, if not altogether in favour of the latter. Both did some fine work, and the mere weight of soil moved by each was something very striking. It is scarcely necessary to say that in consequence of the extreme drought which has for so long a period prevailed, the ground was in a very hard and baked condition, and the clods turned up were in many instances more like stones than arable soil. Still, this condition of circumstances enabled one to judge of the splendid power steam places at the disposal of the farmer. The difficulty of a decision is increased by a variety of circumstances, such as the state of the soil, and the burnt dried-up condition of the herbage, which has had the curious effect of making the smashed-up plots look, when viewed at some distance, as if they had not been smashed-up at all. This of course necessitates a close inspection over the plots themselves, and this again, in many respects, cannot give the same effect as looking over the plots as finished performances; as the French say, there is no *coup d'œil* by which the whole can be taken in at a glance, at least our eyesight did not enable us to do so. There will also be divided opinions as to the merits of the respective tackle. Messrs. Fowler's alone was on the "direct" system, all the others working on the "roundabout" plan. As in other departments, so in this, there is really much to be said on both sides, while debating upon the respective merits of the two systems. Mechanically, the "direct" system is much to be praised; but then the mechanical considerations are not alone those which should be taken into account, as the agricultural points must also be considered *pari passu*.

In gathering up the practical details of the work done on Saturday we shall give statements, showing *first* the extent of each plot; *second*, the amount of work done, or the weight of soil lifted, on each plot; *third*, the time occupied in doing the work, including setting the tackle; *fourth*, the number of people and horses employed in setting down and working the tackle; *fifth*, the depth which the implements worked, and the speed at which they worked—that is, the time they took to traverse each bout or length of the plot. We shall, after giving these, show the power of the engines doing the work so detailed; and so, by means of all these heads, afford a fair and, we believe, accurate account of what was done.

Following up the above arrangement, we find that the extent of each plot was as follows:—

No. of Plot.	Name.	Breadth. Yards.	Length. Yards.	Square yards.	Area in acres and in fractions of an acre.
1	Aveling .....	24	359	8216	1.28
2	Howard .....	46	331	10636	2.19
3	Tasker .....	46	331	9945	2.05
4	Fowler's clip-drum and self-moving anchor	46	194	8924	1.84
5	Hayes.....	—	—	—	—
6	Fowler's dbl. winding-drum .....	42	145	6090	1.36

We now come to the second head, the amount of work done, or weight of soil lifted, on each plot:—

No. of Plot.	Name.	Weight of ground moved per sq. yard in pounds.	Area of work per hour in sq. yards.	Weight in pounds.	Weight moved per hour and horse power.
1	Aveling .....	437½	9200	949050	94905
2	Howard .....	411	4458	1832340	183234
3	Tasker .....	316	2836	898016	89803
4	Fowler's clip-drum .....	430	4866	2048790	255405
5	Hayes.....	182	—	—	—
6	Fowler's dbl. winding-drum .....	502	4566	229213	239213

The results in the second column were obtained by enclosing, by means of a box of the requisite dimensions, one square yard of the land ploughed by the competing implements, and then by a spade sharply cutting down the soil all along the edges of the enclosing-box. And further, by lifting the soil clean out to the depth to which the implement worked; this being carefully done so as to expose the bottom as much as possible in the same condition in which the implement had left it: and so securing a two-fold result in the weight, and the state of the sole or pan left by the implement in passing over the ground. As regards the latter test, however, we do not place much value upon it, the area of the sole exposed being far too limited to admit of any accurate conclusions as to the average condition of the sole left by the implement over the whole plot cultivated. An examination of the column of weight of soil in pounds lifted per square yard, will show a discrepancy between that given in the table at the end of our last week's report, so far as regards the relative weight lifted by Howard and by Aveling, but it may be explained thus: Mr. Aveling objected to the decision or result arrived at by the first trial of weight; or at all events, if he did not object he expressed a wish to have his weight still further tested as compared with Howard's; the result, we believe, of five weighings having the effect of almost practically transposing the positions of the two. We come now to the third point, namely, the time occupied in doing the work including the setting of the apparatus:

No. of Plot.	Name.	Time setting down	Time working.	Total.
		h. min.	h. min.	h. min.
1	Aveling ... ..	0 48	2 48	3 36
2	Howard ... ..	1 5	2 23	3 28
3	Tasker ... ..	0 44	3 31	4 15
4	Fowler, clip drum ...	0 38	1 50	2 32½
5	Hayes... ..	1 45	—	—
6	Fowler, double winding drum ... ..	0 25	1 20	1 45

The fourth point takes the number of people and horses employed:

No. of Plot.	Name.	Men.	Boys.	Horses.
1	Aveling ... ..	5	1	none
2	Howard ... ..	5	2	8
3	Tasker ... ..	5	2	2
4	Fowler, clip drum ...	3	2	none
5	Hayes... ..	5	2	9
6	Fowler, double winding drum... ..	3	2	none

The depth at which the implements worked, and the time they took to traverse the length of bout, are shown in the following:

No. of Plot.	Name.	Average time taken to do the bout, in minutes.	Length of bout, in yards.	Speed per minute, in yards.	Depth of working, in inches.
1	Aveling ... ..	6	259	43	7 to 9
2	Howard ... ..	8	281	77	6 to 8
3	Tasker ... ..	2 5-6th	221	78	6 to 7
4	Fowler (clip) ... ..	2 5-6th	194	69	8 to 9
5	Hayes... ..	—	—	—	3 to 4
6	Fowler (double drum) ... ..	2 1-6th	145	68	10 to 11

The power of the engines and length of stroke and character of cylinder are given in the following:

No. of Plot.	Name.	Diameter of cylinder, in inches.	Length of stroke, in inches.	Nominal horse-power.
1	Aveling ... ..	10½	12	10
2	Howard ... ..	11	13½	10
3	Tasker ... ..	7½ 2 cylinders	12	10
4	Fowler (clip drum) ...	8½	12	8
5	Hayes... ..	10½	16	10
6	Fowler (double drum) ... ..	10	12	10

On Monday the fine weather still continued as in last week, but not so the heat, for that simply had increased; and no easy work was it to go through with the labours of the field. The great feature of the day was the trials of the steam cultivators under the dynamometer. A very long time was spent in getting the dynamometer arranged for work, a task of no small difficulty, if one might judge from what we saw. The result was that it was approaching evening before the trial began, at least it was far on in the afternoon—and it was late, in the evening, before work was concluded. The following affords a glance at what was

done by the judges, Messrs Bramwell, Cowper, Coleman, and Rooke; while the experiments instituted had for aim the power which each implement took to work it, the period of trial being two minutes. The first implement tried was Howard's two-furrow plough, No. 1,199; but in consequence of the state of the land only one breast was used. The time taken in going 111 yards was  $1\frac{1}{2}$  minutes, and the index of the dynamometer registered 31.03. The second bout was 113 yards; the time 2 minutes, and the index registered 36.05. The third bout showed distance 123 yards; time 1.59 minutes; register of index 4 5.09.

The second implement put under trial was Messrs. Fowler's two-furrow plough, Kent breast. The length of the bout was 87 yards; the time  $1\frac{1}{2}$  minutes, and the register of index 47.02. The second bout was 51 yards in length; the time  $1\frac{1}{2}$  minutes, and the registration of index 34.11.

The third implement put under trial was Fowler's four-furrow Kent breast, the first bout of which was 102 yards in length; the time taken 2 minutes, and the registration of index 60.98. The second bout was 119 yards in length; the time taken 2 minutes, and the index registration 67.49.

The fourth trial was Howard's four-furrow plough: the length of the bout 84 yards, the time  $1\frac{1}{2}$  minutes, the registration of index 30.61. The second bout: 117 yards; time 2 minutes, registration 52.95.

The fifth trial was of Messrs. Fowler's five-furrow digger, the first bout of which was 107 yards in length: the time taken, two minutes, and registration 63.62. The second bout was in length 108 yards: the time taken,  $1\frac{1}{2}$  minutes, and the registration of index 63.95. The following gives, in another form, the results of this day's trials:—

	Howard's 1-furrow plough.			Fowler's 2-furrow plough.		Kent-breast.		Fowler's 4-furrow plough, Kent-breast.		Howard's 4-furrow plough.		Fowler's 4-furrow digger.	
	(a) in.	(b) in.	(c) in.	(a) in.	(b) in.	(a) in.	(b) in.	(a) in.	(b) in.	(a) in.	(b) in.	(a) in.	(b) in.
Breadth .....	16	16	16	30	30	30	40	40	40	40	40	40	40
Depth .....	12	13	14	14	14	14	9	9	9	6	6	8	8

Average .....	8.6			7.4		8.65		9.0		8.45		8.45	

The work going on in the other parts of the field was the trial of clod-crushers, with selected implements for final decision from (1) Beverley Iron and Waggon Company; (2), Amies, Barford, and Co.; (3), Crosskill and Co.; Beverley; (4), Cambridge and Co. The general-purpose-ploughs trial selection of implements for final decision was carried out in another part of the field, the following being the chosen competitors: (1) Howard, (2) Hornsby, (3) Ransomes, (4) Cooke and Co., (6) Ball and Son, (6) Lewis.

On Tuesday the dynamometer trials of the various ploughs were commenced, the ploughs being dragged by one of Messrs. Fowler's engines; the trial of the "windlasses," of the straw elevators going on in another field; while the trials of the cultivating implements for steam were conducted under the same arrangements as yesterday. The following gives a general view of the results of these last and most important trials:

The first trial was made with Howard's one-furrow breast deep plough, which took an average depth of 12 inches, with a total width of 16 inches, and the draught of which averaged a 5.6lbs. to move one square inch of soil.

The second trial was of Fowler's two-furrow deep plough, with Kent breasts or mouldboards, and which with an average depth of  $14\frac{1}{2}$  inches had an average draught of 7.4lbs. to move a square inch of soil.

The third trial was of Fowler's four-furrow plough, with Kent breasts, which with a breadth of 40 inches took an average depth of  $9\frac{1}{2}$  inches, and required a draught (average) of 8.5lbs. to move one square inch of soil.

The fourth trial was with Howard's four-furrow plough, which taking a width of 40 inches, and an average depth of 6 inches, required a draught of 9lbs. to move one square inch of soil.

The fifth trial was with Fowler's five-furrow digger, with a breadth of 50 inches, and an average depth of 8 inches, taking a draught of 8.45lbs. to move a square inch of soil.

The sixth trial was with Fowler's five-tine cultivator, which with a breadth of 50 inches, and an average depth of  $5\frac{1}{2}$  inches, took an average draught of 11.95lbs. to move one square inch of soil.

The seventh trial was with Howard's four-tine cultivator, with a breadth of 40 inches, and, taking an average depth of  $6\frac{1}{2}$  inches, took a draught of 10.5lbs. to move a square inch of soil.

The eighth trial was with Smith's (of Woolston's) three-tined cultivator, worked by Tasker and Sons, of Andover, which taking a depth of 6 inches, and a breadth of 36 inches, required a draught of 5.6lbs. to move a square inch of soil.

The ninth trial was with Howard's four-furrow digger, taking an average depth of  $5\frac{1}{2}$  inches, with a breadth of 40 inches, and required a draught of 13lbs. to move a square inch of soil.

The tenth trial was of Fowler's four-furrow digger, which taking a breadth of 40 inches, and a depth of 9 inches, required a draught of 9.8lbs. to move a square inch of soil.

The eleventh trial was of Smith's (of Woolston's) five-tine cultivator, worked by Hayes, of Stoney Stratford, which taking a breadth of 33 inches, and a depth of 4 inches, took an average draught of 16.8lbs. to move a square inch of soil.

The twelfth trial was of Fowler's nine-tine turning implement, which taking a breadth, in one case of 70, and in a second that of 90 inches, with a depth of 3 inches, took a draught of 9.5lbs. to move a square inch of soil.

The thirteenth trial was with Howard's nine-tine implement, which took a depth of  $4\frac{1}{2}$  inches, with a breadth of 90 inches. We have no record of the draught of this implement.

We have previously alluded to the magnificent display of steam-cultivating machinery exhibited on the field by the Messrs. Fowler, of Leeds. This firm had five

different systems at work in one field, in connexion with the working of which the following statements will, we are assured, be of great interest to our readers.

**1st system:** Two ten-horse power double steam engines with single winding-drums. This worked a five-tined cultivator, taking a breadth of fifty inches, and moving over the field at a speed of forty-six yards per minute: this did, at the depth of from ten to twelve inches, an amount of work equal to 8,870 square yards per hour.

**2nd system:** Two ten-horse power double engines with single winding-drums, working a seven-tined cultivator, with only six tines however working, and which took a breadth of sixty inches. The speed was forty-two and a-half yards per minute, and the work done per hour was 4,212 square yards, at a depth of eight inches.

**3rd system:** Two ten-horse power double engines with single winding-drums, working a four-furrow plough with digging breasts, taking a width of forty inches, a depth of from eight to nine inches, and going at a speed of sixty-one yards the minute, doing work per hour equal to 3,900 square yards.

**4th system:** Two ten-horse power double engines with double winding-drums, working two implements, being five and six-tined cultivators, taking respectively breadths of fifty and sixty inches, with depths from seven to nine inches. The work done was in this case 8,742 square yards.

**5th system:** One ten-horse power double engine with self-acting anchor. This worked a four-furrow plough with Kent mould-boards, taking a breadth of forty inches, a depth of nine inches, and doing per hour 3,360 square yards.

The work done in more than one instance was really something remarkable, that by the Messrs. Fowler specially so; this was very deep, with a good flat sole, and the clods were thrown up in that style so well calculated to aid the atmospheric influences, or rather to allow them to operate; for these, when allowed to act, form the best cultivators. Nor must the work done by the Messrs. Howard be overlooked, this being also very good.

As the Leicester is probably the largest of all the meetings of the Royal Agricultural Society, so also it has succeeded in obtaining the best possible site for carrying on the operations of the stock and implement shows. On an open plateau overlooking the plains below, and over which the breezes blow freely, and most welcome, an area is enclosed not far off fifty acres in extent, over which the various stands are laid out. One excellent feature is that the implement stands, containing what may be called the passive department of machinery, are arranged in two parallel rows; and, on each side comes the machinery in motion—which may be called the dynamical department, in such positions that each stand of the exhibitor who exhibits machinery in motion is exactly opposite the end of the implement stand where the machinery at rest is exhibited. This simple arrangement enables the visitor or purchaser at one stand to go at once to the other if he so desire. At the termination of each row of the implement stands are placed the words "Shed A," "Shed B," and so on: but these give no indication of the "catchword" of the catalogue so to call it, which goes by the number of the stands. Such, therefore, as are desirous to go to some particular shed, and who does not care to hunt up the index, or do not know how to do so—for the index and its catalogue are not arranged in the best possible way—would most heartily welcome some such placard at the end of the shed as this: "SHED A—Stands No. 1 to 20 inclusive." The more trouble one takes the more trouble is saved.

## PRIZES FOR IMPLEMENTS.

### JUDGES:

Steam Cultivators: J. F. Bramwell, C.E., Great George Street, London; J. Coleman, Eecrick Park, York; E. A. Cowper, Great George Street, London; J. Hemaley, Skelton, Newark; J. Rooke, Weldon Grange, Wansford.

Tile Machines and Miscellaneous: H. B. Caldwell, Moncton Farleigh, Bradford, Wilts; J. Thompson, Badmington, Chippenham; E. Wortley, Ridlington, Uppingham.

Ploughs: T. P. Dods, Anick Grange, Hexham; G. M. Hipwell, Elmore Lodge, Sutton, Surrey; J. Wheatley, Newick, Driffield.

Cultivators, Clod Crushers, Rollers, and Harrows: T. Chambers, Jun., Colkirk Hall, Fakenham; W. Roberts, Thorneyholme, Burnley; F. Sherborn, Bedford, Middlesex.

### STEAM CULTIVATION.

Special prize of a silver gilt cup and six drinking cups, offered by the Pasha of Egypt, "for the steam cultivating apparatus combining strength with usefulness, with the least amount of repairs, which cannot be readily executed in foreign parts"—Messrs. Fowler, Leeds, for their "double-engine set of tackle with single winding drum."

The best application of Steam Power for the cultivation of the Soil: First prize of £100, J. Fowler and Co.; second of £25, J. Fowler and Co., for one double drum traction engine working with a travelling disc anchor, and £25 for one traction engine working with clip drum and travelling disc anchor.

The best application of Steam Power adapted for occupations of a moderate size: First prize of £50, J. and F. Howard; second prize withheld.

Implements for Steam Cultivation, including Ploughs for Steam Power, Cultivators, Harrows, Windlasses, Anchors, Rope Porters, &c.: £12, J. Fowler and Co., for four-furrow balance plough fitted with Kent breasts and convertible into digger; £12, J. Fowler and Co., for seven-tine balance cultivator (large occupations); £12, J. and F. Howard, for five-tined cultivator (occupations of a moderate size); £15, J. Fowler and Co., for light land cultivator single acting (new implement); £8, J. Fowler and Co., for frams for harrows, rollers, &c.; £7, J. and F. Howard, for harrows; £10, J. Fowler and Co., for disc travelling anchor; £8, J. Fowler and Co., for double disc windlass on engine; £8, J. Fowler and Co., for clip drum windlass on engine; £8, J. and F. Howard, for double drum windlass on frame; highly commended, J. Fowler, for three-furrow balance French plough (deep work); J. and F. Howard, for two-furrow plough (deep work).

Tile and Brick Machines: £7 10s., J. Whitehead, for brick machine; £7 10s., J. Whitehead, for tile machine; £5, J. D. Pinfold, for brick machine.

Draining Tools: Silver medal, Hunt and Pickering.

Wheel Ploughs: (general purpose) £9, J. and F. Howard; £5, Ransomes and Sims; (light land) £6, J. and F. Howard; £4, Ransomes and Sims; (deep land) £6, Ransomes and Sims; (general purpose) highly commended, R. Hornsby and Sons; (light land) R. Hornsby and Sons; (deep land) J. Cooke and Co.; (deep land) commended, R. Hornsby and Sons.

Swing Ploughs: (general purpose) £5, J. and F. Howard; £4, Ransomes and Sims; (light land) £5, J. and F. Howard; £3, Ransomes and Sims; (general purpose) commended, J. Cooke and Co.; R. Hornsby and Sons; Ball and Son; (light land) R. Hornsby and Sons.

Subsoil Ploughs: £6, J. and F. Howard; £4, Ransomes and Sims; (digging ploughs) highly commended, R. Hornsby and Sons, J. and F. Howard, Ransomes and Sims.

Paring Ploughs: £6, Ransomes and Sims; £4, J. and F. Howard; highly commended, Ball and Son.

Cultivators: £13, E. H. Bentall; £7, C. Clay; highly commended, Hunt and Pickering.

Clodcrushers: £11, Beverley Iron Works Company; £9, Amies, Barford, and Co.; highly commended, W. Crosskill and Sons; commended, E. Cambridge and Co.

Rollers: £6, Amies, Barford, and Co.; £4, Beverley Iron Works Company; highly commended, Amies, Barford and Co.; commended, William Lewis, Holmes and Sons.

Harrows: £13, J. and F. Howard; £7, Ransomes and

Sims; highly commended, Ashby and Jeffery, W. F. Johnson, H. Denton, Holmes and Sons; commended, E. Cambridge and Co.

Miscellaneous: Silver medals, Ransomes and Sims, for turnwrest ploughs with patent wheels; Hunt and Pickering, for collection of draining tools; Amies, Barford, and Co., Peterborough, clod crusher and roller; The Beverley Iron Company, Beverley, pair of patent wrought iron wheels; Bryan Coreoran and Co., London, diamond millstone dressing

machine; J. Lee, Norton, London, tub well and pump, also nine-inch revolving Archimedian screw ventilator; Clayton and Shuttleworth, Lincoln, patent combined revolving liquid manure and drop drill; H. R. Marsden, Leeds, steam stone breaker; W. Smith, Kettering, grindstone frame for grinding reaping machine knives; W. Coleman and Peter Lowe, Northampton, combined 6-in. trough with self-supporting action; and Aveling and Porter, Rochester, patent road locomotive crane engine.

## THE BEET-SUGAR QUESTION.

BY THE OLD NORFOLK FARMER.

The history of the discovery of sugar in plants of European growth forms an important era in the annals of European commerce. It has led to the creation of a manufacture of a material that is at once a luxury and a necessary of life, a healthful condiment and an agreeable and universally acceptable auxiliary to the minor delicacies of the table. Like salt, its moderate use assists to purify the blood and materially promotes the digestion of food, imparting warmth to the system and favouring the acquisition of fat. From being in the first instance a luxury of so costly a kind as only to be obtained and enjoyed by the wealthier classes, it has now become so cheap as to be within the means of the working orders, and is in constant use in the cottages of the peasantry. Such is sugar in the domestic economy; and we propose tracing its history from the earliest period to the present time.

It is well known that, until a comparatively recent period, the only plant from which sugar was obtained was the sugar cane, a native of tropical climates, and was undoubtedly indigenous in the East Indies. It was unknown to the ancient Greeks and Romans until the time of Alexander the Great when it became known to the former through one of their generals—Nearchus—about the year B.C. 325. It was, however, used by the Hebrews, being mentioned by the Prophet Isaiah under the name of *kend*, or "sweet cane," and the extract from it was termed *sakar*, or *sheker*, which is synonymous with the Greek word for sugar, and signifies intoxication. We may trace the knowledge of this plant and the extract obtained from it from the time of Alexander, through the writings of most of the extant ancient authors. Strabo mentions its introduction into Europe by Nearchus; Varro (B.C. 66) describes a liquor pressed from the cane "as sweet as honey." Dioscorides (B.C. 35) mentions a kind of honey brought from the East Indies, "like salt, and brittle when chewed." He describes it as possessing highly medicinal qualities. Galen also prescribed it as a medicine; and Lucan, in the first century, speaks of the juice as being used as a common beverage; Arrian, as an article of commerce between India and the countries bordering on the Red Sea. Ælian, Tertullian, and Alexander Aphrodisiensis describe it as "a kind of honey extracted from the cane."

Marco Polo, the first Eastern traveller of comparatively modern times, found manufactured sugar in abundance in Bengal. This was in the middle of the thirteenth century; and at the close of the fifteenth, Vasco de Gama, having doubled the Cape of Good Hope, found that a considerable trade in sugar was carried on in the kingdom of Calicut.

It is, however, certain that before the time of either of these two last-named travellers, the cane had been introduced by the Saracens into Western Europe. Albertus Amiensis, a monk who wrote at the time of the Crusades, states that the soldiers in those expeditions derived both refreshment and support from the juice of the cane, which was then introduced into the Morea, the Island of Rhodes, and Malta, and from thence into Sicily, where it was cultivated and manufactured into sugar about the beginning of the 12th century.\* It was soon after taken to Spain, and, in the 15th century, to Madeira, the Canaries, and the Cape de Verd Islands; and thus, at the period of the discovery of the New World by Chris-

topher Columbus, it was cultivated in every part of Europe where the climate and soil were favourable to its growth.

We come now to the question respecting the introduction of the sugar-cane into the New World, on which there appears to have been a great deal of controversy. If we are to believe those eminent writers Peter Martyr and Cardinal Ximenes, who were contemporaries of Columbus, we must admit that the sugar-cane is an indigenous production both of the American Continent and of the West Indian Islands. The first of these writers asserts that it was certainly found by the Spaniards at Hispaniola upon their arrival; and the Cardinal, in a "Treatise on American Plants," asserts that the sugar-cane grew there without cultivation to a very large size, especially on the banks of the river La Plata; and this statement is confirmed by Jean de Lory, the chaplain of the Dutch garrison at Fort Coligny in 1556, who also found the cane on the banks of that river, "where no European had ever before penetrated"; and the accounts of these three writers are further confirmed by the absence of all direct evidence that Columbus conveyed it thither, and the certainty that upon his second voyage to the "Indies" the Spaniards were cultivating it at Hispaniola.

On the other hand, Professor Humboldt, after a most elaborate literary research, both in the Old and New Worlds, has come to the conclusion that the sugar-cane is not indigenous in the New World, and that the natives both of the continent and of the islands were entirely unacquainted with either the sugar-cane, rice, or any of our cereal plants, except maize; and that the first of these was most probably conveyed thither by Columbus himself. It certainly appears a confirmation of this opinion that the cane was not cultivated in Barbadoes and the British West Indies until the middle of the 15th century, or about 150 years after the discovery of America.

With such a contrariety of opinion amongst men of the most extensive learning and research, it would be impossible, even if necessary, for us in the present day to arrive at any satisfactory conclusion on this question. It is, however, enough for us to know that from the time of the occupation of the West Indies by Europeans, the best and most abundant supply of sugar has been brought to Europe from that quarter; and that up to a recent period the sugar cane has been the only plant from which it has been extracted. The experiments of science have thrown additional light on this subject within the last few years; and it is to the discoveries thus made, by which the property of yielding this most useful substance, is found to be possessed by many, if not all, other plants, that the attention of the reader is now requested.

Before, however, entering more immediately on this subject, it may be proper to state that there are two kinds of sugar, possessing different characteristics, and requiring different processes in their manufacture. The first and best of these is extracted from the cane, the Silesian beet-root, and the maple. This species of sugar crystallizes into oblique four-sided prisms, terminated by two-sided summits. The three species named are identical in their properties and composition, when similarly manipulated, except that the product of the beet-root is said to be the strongest in saccharine power, and forms the finest crystals. The manufacture of sugar from these plants is entirely a mechanical process, requiring no chemical additions or changes except the condensation of the juice, the natural effect of the heat employed.

The second kind, which is termed "a factitious" sugar, is produced from the grape and other ripe fruits, and starch or

\* In the year 1166, William II., King of Sicily, made a donation to the Monastery of Saint Benoit of a mill for grinding the sugar-cane, with all its rights, members, and appurtenances, &c., &c.—*Lactian*.

farina, such as is produced from our cereal plants and the potato. This kind is more like the East India sugar, not forming regular crystals, but settling into tufted concretions, like the head of a cauliflower. The farina being itself a residuum, obtained by a mechanical process, is converted bodily into sugar by the addition of a chemical agent. In fact, there is a considerable increase in the weight of sugar produced over that of the farina employed, so that one cwt. of the latter will yield one and a quarter cwt. of the former. This, which appears anomalous at first sight, is easily accounted for, when the process by which the transformation is effected is explained. The farina is necessarily highly dried, and it requires the addition of a large quantity of moisture to convert it into sugar; and a considerable portion of that moisture remains in the sugar when the process is completed, which constitutes the excess in the manufactured article. With regard to the grape and other ripe fruits, they contain large quantities of saccharine matter, or its bases, but in this country they bear too high a price to be employed in its manufacture. Both these factitious sugars prove, upon analysis, greatly inferior to the first kind, bearing a proportion of saccharine power of not more than 60 to 100. It is evident that, as the sugar maple does not grow in the United Kingdom, as fruits are too scarce and costly, and as the potato also has for some years borne too high a price to make its manufacture into sugar feasible, we are, with our present knowledge of the saccharine properties of plants, restricted, so far as regards home-grown sugar, to the use of the Silesian beet-root, to which we shall now address ourselves.

It was in the year 1747 that a celebrated German professor of chemistry (M. Margraaf), having found in the course of his experiments, but quite by accident, a portion of sugar in some plants, determined to make a general analysis of all plants of domestic growth. By following up this resolution, he ascertained that the Silesian beet-root yielded the largest proportion. Having made this discovery known, the beet-root began to be cultivated for the purpose in various parts of Germany; and was also introduced into Prussia by M. Achard, who in 1799 published his method of manufacturing the sugar from the Silesian beet-root, the product being then estimated at 34 per cent., and the cost at 3d. per lb.

The particular kind of beet-root from which the sugar is obtained is a species of the *Beta vulgaris*. It has a white or pinkish outside, and presents the appearance of a cellular tube, replete with a clear, transparent juice, in the large proportion of 95 or 96 of liquid to 5 or 4 of solid ligneous fibre. The physical properties to be sought for in the beet-root are firmness and brittleness of texture, perfect soundness of inside, and sweetness of juice. On being cut across, a good root will emit a creaking sound under the knife, and a slice, held up to the light, will appear semi-transparent.

So far as any practical result is concerned, the discovery by M. Margraaf remained a dead-letter, and the fact itself of the existence of sugar in the plants of European growth was looked upon rather in the light of a scientific curiosity than as possibly leading to any practical consequences. It was upwards of fifty years, and up to the close of the last century, before the possibility of turning it to account was entertained; when the necessities of a neighbouring nation led to an attempt to make the discovery available. At that period the war which was raging between England and several of the continental Powers had greatly interrupted the trade between France and the West Indian Islands, those belonging to France having been taken by the British fleets in the course of the conflict. France had also lost St. Domingo, from whence she had previously obtained her largest supply of sugar; and thus her entire supply of West India sugar and other produce was cut off. In this dilemma the French Directory, and afterwards the Imperial Government, were induced to encourage, by premiums and other means, the cultivation of the beet-root, and the manufacture of sugar therefrom. In consequence of this, large establishments were formed for the purpose in France, Belgium, and other of the continental States. The price of sugar indeed—especially when the Berlin and Milan decrees were enforced, when it rose to 4f. or 5f. per kilogramme—was of itself a sufficient stimulus; and the manufacture was accordingly prosecuted with extraordinary vigour and success. Great improvements were also made in the processes, by which the product of sugar was increased to 5 per cent. and the quality somewhat improved.

It was by this means alone (if we except what was smuggled into the continental ports, which could not be absolutely prevented) that France and the nations she had conquered obtained their supply of sugar until the restoration of peace in 1815. By the treaties then entered upon, some of the islands taken from France were restored to her, by which means the beet-sugar came into competition with cane-sugar; and the superiority of this latter gave it such a preponderance in the market that the manufacture of the beet-sugar declined, notwithstanding a heavy protective duty was imposed upon the cane-sugar of foreign growth. It is true the beet-sugar thus made was wretched stuff—such as nothing but absolute necessity would have led to its use—consequently, as soon as it came into competition with the West India product, the manufacture declined, and in 1827 was reduced to so low an ebb that it became doubtful whether it would be worth any attempt to uphold it. In 1827-8, only 4,800 tons were produced in France.

From that time, however, efforts were made to improve the processes employed in the manufacture and in the machinery. These efforts were so successful, that not only was the proportion of crystallised sugar obtained increased from five to seven, eight, and even nine per cent. in some instances, but the quality was brought up to that of the cane-sugar, the West India Muscovado. The progress of improvement has gone on continually; and now the process of manufacture, which formerly occupied many days, has been so much shortened that the beet-root taken into the factory in the morning may have its juice converted into excellent raw sugar before night. We may add that most, if not all, the beet-sugar consumed on the Continent is loaf or refined sugar; but a large quantity of raw sugar in an imperfect state is exported from France and Belgium to this country for refining purposes, one house alone importing 300 tons per week. In fact, a considerable proportion of the sugar consumed in the United Kingdom is beet-sugar; and the quality of the refined portion is so far equal to that from cane raw sugar, that no consumer would be able to tell the difference. By a pneumatic process invented by Mr. Crosley the flavour of the beet-root, which formed an objection to the sugar, is now got rid of, and the refined sugar is as free from the flavour as possible; and by the employment of the centrifugal machine the syrup is separated in the most complete manner. We have ourselves seen the black mass of saccharine matter put into this machine, and in five minutes converted into pure white raw sugar.

Many other important improvements have been of late years introduced into this manufacture. Thus in 1757 Dr. Hales discovered that, by the injection of streams of atmospheric air into liquids in a state of ebullition, whilst reducing the temperature, the evaporation is at the same time accelerated. This important experiment and its result were lost sight of for nearly a century, not being considered applicable to any useful purposes. But in 1818 Messrs. Croxley and Galsworthy, the manufacturers of sugar-works machinery, applied it experimentally in a sugar refinery, but in the first instance did not succeed. They, however, renewed the experiment in 1835 with more suitable apparatus, and with the most complete success, discovering at the same time that, by the process, the sugar was divested of whatever impure or offensive taste or smell it might possess, as was formerly the case with the beet-sugar, which was the greatest obstacle to its being used as raw sugar. The principle of this process is illustrated by the daily effect of atmospheric air, agitated by the wind, in evaporating the moisture from the earth or any substance exposed to its influence; and it is by the same means that deleterious and obnoxious gases of every kind are taken up and dispersed, so as to render the air next the earth, where alone it is applied to the subsistence of animal and vegetable life, pure and salubrious.\*

\* This principle of pneumatic evaporation is applied in a very simple but efficient way, during the winter months, by the Northern Tartars, in the preservation of milk. They place it in shallow pans, and expose it to the cold winds during frost. In a short time a dry, white, crispy substance is found on the surface, which is carefully scraped off and put into bottles. This process is repeated until the whole of the aqueous portion of the milk is evaporated, and a sweet white substance, which is essentially *sugar of milk*, is thus obtained, which may be kept any length of time, in any climate, if kept

This process was tested by Mr. Croaley in 1838, upon a quantity of syrup made in the month of June, from beet-root in a state of decomposition, and vegetating. From it he produced raw sugar of pure quality, and as strong in saccharine as the best cane sugar. In fact, when it was exhibited to some of the principal beet-sugar manufacturers at Paris, by a gentleman attached to the British Embassy, they would not believe but that it was cane sugar, and that the party was practising an imposition upon them; consequently they rejected the statement altogether.

Another important discovery was made, to the effect that by a peculiar process, refined sugar (loaf) may be made as well and as speedily from the syrups as from the raw sugar, which latter had previously been the practice. By this invention both expense, time, and labour are greatly economised, for the process has now for many years been in full operation at the best sugar factories on the continent, where, as we have already stated, loaf-sugar is much more generally used than in the United Kingdom. So greatly have the processes been accelerated by this and other discoveries, that refined sugar is now produced from the raw syrup in 48 hours. Those persons, therefore, whether in the United Kingdom or on the Continent, who embark in this manufacture, will have the advantage of the sixty years' experience, experiments, and improvements of the Continental sugar manufacturers, both in the adaptation and the application of machinery and utensils, in the immediate adoption of the most efficient processes, and in the general economisation of the entire routine of manufacture. This is no mean or trifling advantage, for vast sums have been expended and sunk in the acquisition of that knowledge on which alone the manufacturer can depend for maintaining a successful competition with the West and East India planters, but which is now open to any one who will take the trouble to acquire it.\*

In consequence of these improvements in the manufacture, the large increase in the proportion of sugar produced, the superiority of its quality, and the evident advantages the beet-sugar manufacturers possessed over the West India planters (which will presently be described), the French government a few years since considered the time was come when the former was enabled to dispense with the protection that had been hitherto given it, to enable it in its infant state to encounter the competition with cane sugar. Accordingly, in 1848, the differential duty previously levied upon imported sugar was annihilated, and the imposts on the two productions were equalized. Of course, the beet-sugar manufacturers complained heavily of this measure, and predicted the ruin of the trade. Far from this, however, they exerted themselves with increased energy both in devising means for increasing the proportion of sugar by more perfect methods of crystallisation, and the general economising of the expenses of manufacture.

In addition to the improvements enumerated above, the continental manufacturers have largely increased the power of their hydraulic presses, by which they have been enabled to obtain a greater proportion of the juice, and thereby also to compress the pulp so effectually, that it will keep for any rea-

dry. This plan, although not practicable here, might be applied to the evaporation of the sap of the maple in Canada, and would produce excellent sugar at a trifling cost.

\* A singular fact has been elicited in the progress of this manufacture, namely, that the beet root in a frozen state yields more sugar than when not frozen; but if suffered to thaw again it yields less than the usual average. It is well known in Canada that, when drawing off the sap from the sugar-maple, if the roots are bare of snow, the sap is weak in saccharine power, and the settlers have learned from the Indians to cover the ground with snow around the tree, and as soon as this begins to melt they draw off the sap, which is then sufficiently sweet. It would appear from this result, that a more definite and extensive formation of saccharine occurs under the influence of congelation, and a more perfect arrangement of the constituents of sugar, which are given as follows by the different chemists named:

	Gay Lussac.	Berzelius.	Prout.	Ure.	Kane.
Oxygen ...	50.63	49.856	53.35	50.33	11
Hydrogen...	6.90	6.879	6.66	6.29	11
Carbon ...	42.47	43.265	39.99	43.38	12
	100.00	100.00	100.00	100.00	34

sonable length of time, if placed in pits sunk in the earth. Carbonic acid also is employed in clarifying the juice, and the passing of steam from one evaporating boiler to another facilitates and cheapens the process of evaporation. The manufacture, therefore, in all its various manipulations, is now arrived at a point of perfection that admits of but little further improvement.

It will perhaps be supposed that the complete pressure of the pulp will drive it at the same time of the entire proportion of saccharine matter it contains; but this is an error. It is found, upon analysis, that the pulp still contains at least 5 per cent. of sugar, after the hydraulic press has performed its office in extracting the last possible drop of juice. It is therefore quite as valuable for feeding purposes as the whole root itself, and as such, is in constant demand with the continental farmers at 14 or 15 francs per ton. When the manufacture was established in Ireland (at Mountmelick), the farmers refused to purchase the pulp, alleging that it must be worthless after the extraction of the sugar; but a merchant of the town, in order to set an example, fed a large number of hogs with it, and found it a very profitable speculation. The question of its value for feeding purposes has long been set at rest on the continent, where it is as regularly returned to the farmers at the price named as the root is sent to the factory.

We shall next proceed to consider the question of the propriety or safety of introducing the manufacture of beet sugar into the United Kingdom, and its influence upon the system of agriculture practised, more especially in England. Before, however, going into this subject, we shall refer to those attempts that have already been made to effect this purpose, and state the causes that led to their failure.

The first of these attempts was made about thirty years since, when three establishments were formed for the purpose. One of these was near Chelmsford in Essex, the proprietors of which were the well-known firm of Marriage and Co., millers. A second was fixed in the south of Ireland, and a third in the north of that country. At the time when this took place there was no duty on indigenous sugar, for the simple reason that the Legislature had never contemplated the possibility of its being manufactured in the United Kingdom. The duty then upon West India produce was about 3d. per pound; consequently the home-made sugar, although, through the imperfection of the machinery, of an execrable quality compared with that of the colonial sugar, found purchasers at 4d. per pound, and paid the manufacturers a handsome profit. But at that period the "West India interest" was still powerful in the House of Commons, and had to be propitiated on the question of emancipation. Under the clamour, therefore, raised by that body, a very heavy differential duty was laid upon indigenous sugar, which at once stopped the works of the three factories; at the same time, acting upon an equitable and impartial principle, the Government intimated to the proprietors that, under the circumstances, if they sent in a fair estimate of their loss, they would be indemnified for it. Accordingly, Messrs. Marriage, and one of the Irish proprietors, received the full amount of their estimates; but the third, having made a claim of £15,000 for what had cost him not more than £5,000 or £6,000, it was at once returned to him, with a refusal to entertain his case at all; and he never received a shilling of remuneration.

The last case was that of the establishment at Mountmelick in Queen's County, Ireland, in 1851, which was commenced under circumstances in every respect calculated to render it both profitable to the company to which it belonged, and most valuable to Ireland, as opening up a new branch of manufacturing industry calculated to benefit all classes of the community.

It would be useless to go into the causes of the failure of this unfortunate attempt, which has tended to discourage those who were desirous of introducing so promising an enterprise into Ireland, where such sources of industry are so much wanted. That the failure of the Beet Sugar Company was in no respect owing to the soil or climate of Ireland not being adapted to the cultivation of the root was abundantly proved by the investigation undertaken by Sir Robert Kane, director of the Museum of Irish Industry, by order of the Chief Commissioner of Works in Ireland, and presented, by command of her Majesty, to both Houses of Parliament. This report, which occupies fifty-four pages, contains, amongst other interesting matters, the analysis of 118 specimens of Irish-grown beet-

roots, carefully conducted, the beet being grown in different parts of the country. The quantity or percentage of sugar they contained ranged from 3.523 (or about  $3\frac{1}{4}$ ) to 14.551 (or  $14\frac{1}{4}$ ), the low average being from large and the high from small roots. This perfectly agrees with the results of analyses, and also with those of working on the largest scale, on the Continent, where it is so well understood that the smaller the root the larger the proportion of saccharine, that the beet is planted at ten inches in the rows and about fourteen inches between the rows, in order thus to produce a dwarfed root. We select the following as specimens taken from the tables in Sir R. Kane's report:

Weight of root.		Sugar.		Weight of root.		Sugar.	
lbs. oz.	per cent.			lbs. oz.	per cent.		
0 13	.....	11 3.5		4 12 $\frac{1}{2}$	.....	9	
1 0 $\frac{1}{2}$	.....	14 $\frac{1}{2}$		5 13 $\frac{1}{2}$	.....	7 1.5	
1 1	.....	13 $\frac{1}{2}$		6 2 $\frac{1}{2}$	.....	7 $\frac{1}{2}$	
1 2 $\frac{1}{2}$	.....	13 4.5		6 5 $\frac{1}{2}$	.....	6 1.10	
2 1	.....	9 4.5		8 0 $\frac{1}{2}$	.....	3 $\frac{1}{2}$	
2 3 $\frac{1}{2}$	.....	9 $\frac{1}{2}$		8 14 $\frac{1}{2}$	.....	3 3.5	
2 6	.....	11 $\frac{1}{2}$		9 7 $\frac{1}{2}$	.....	3 $\frac{1}{2}$	
3 6 $\frac{1}{2}$	.....	20 2.5		9 8 $\frac{1}{2}$	.....	2 $\frac{1}{2}$	
3 6 $\frac{1}{2}$	.....	7 $\frac{1}{2}$					

It should be observed that the condition and quality of the soil have much to do with the proportion of saccharine, which will account for any discrepancies in the proportions of sugar in some of the above specimens; but, on the other hand, the very small proportion of sugar in the large roots compared with that of the small ones is too palpable to admit of a doubt as to the fact of the superiority of small roots for the purpose of producing sugar.

Now, by way of comparison, the report contains also the analyses of seven specimens of roots from Belgium, the results of which are as follows:

Weight of roots.		Sugar.		Weight of roots.		Sugar.	
lbs. oz.	per cent.			lbs. oz.	per cent.		
1 3	.....	10 $\frac{1}{2}$		3 8 $\frac{1}{2}$	.....	8 1.6	
2 5	.....	9 $\frac{1}{2}$		3 14	.....	7 4.5	
2 14 $\frac{1}{2}$	.....	9 $\frac{1}{2}$		5 7 $\frac{1}{2}$	.....	10 $\frac{1}{2}$	
3 3 $\frac{1}{2}$	.....	8 $\frac{1}{2}$					

If the two tables are compared, it will be found that the proportions of saccharine in the Irish beet, without any previous preparation of the soil, is, on the whole, quite equal to that in the Belgian, where the peculiar mode of cultivation (with liquid manures) and the greater coldness of the climate give a decided advantage to the root, in regard to the proportions of sugar it contains.\*

But Sir R. Kane and his coadjutors did not confine their investigations to the analysis of single roots; they also undertook to apply a more practical test, by an actual manufacture of sugar—on a comparatively small scale it is true, but sufficiently large for the purpose. They were supplied with the necessary apparatus by Mr. Croley (formerly of the firm of Croley and Galsworthy), capable of operating upon from 20 to 25 cwt. of root. The first experiment was a failure,

\* The following are the entire results of the 118 analyses: 12 contained above 12 per cent. of sugar.

† In the evidence given before the Committee of the House of Commons in 1847 it was stated by planters that the average product of crystallized sugar was not more than 6 per cent., with about an equal quantity of molasses.

owing to circumstances it is unnecessary to state here. The second was employed on ten cwt. of beetroot, and the result was as follows: 30.17 per cent. of pulp or residue, 6.51 of raw sugar, and 1.63 of molasses—in all, 8.14 of saccharine matter. There is no doubt that with proper machinery, on a large scale, and after much experience, a larger and better product would be obtained. It is the general opinion of the chemists that the whole of the saccharine matter is crystallizable, under favourable circumstances, and that the molasses are the result of extraneous matters in the juice, which to a greater or less extent counteract the crystallization: much in this respect depends upon the manure employed, both as to the per-centage of saccharine and its purity. We shall have occasion to refer to this part of the subject when speaking of the cultivation of the beetroot.

The clamour raised by political economists against the manufacture of beet-sugar in the United Kingdom is but a reiteration of what was expressed a few years since against the same object in France. Mr. McCulloch, in his Commercial Dictionary, published in 1847 (p. 1256), makes the following observations. Speaking of the plan adopted by the French Government of raising annually the duty on beet-sugar until it became equal to that on sugar from the French colonies, he says: "This system came into operation on the 1st August, 1844, and in August, 1848, the equalisation of the duties will be effected. The probability is that, if fully carried out, this project will go far to annihilate the growth of beet-sugar in France; and if so, there will be, between the present period and 1849, an increased demand in France for tropical sugar, equivalent to a part, at least, of the supply which is now derived from beetroot. The same cause which has extended the growth of beet-sugar in France—viz., its exemption from all duty, while it comes into competition with an article loaded with a heavy duty, has introduced its culture in Belgium, Germany, Prussia, and even Russia. Beetroot plantations have increased most in Silesia and Saxony, and supply a considerable portion of the sugar made use of in those countries."

Now, how has this bold prediction been verified by the facts? So signally has it failed of accomplishment that the equalisation of the duty, instead of annihilating the manufacture, has not been sufficient to protect the tropical sugar in competition; and the French Government has inflicted a differential duty of 5 francs per cwt. upon beet-sugar above what the tropical sugar pays, in order to enable the latter to meet the competition. And so far is the manufacture from having been annihilated by this increase of duty that it has increased to double its amount in 1850, as the following statement will show:

#### PRODUCE OF BEET-SUGAR MANUFACTURE IN FRANCE.

Year.	Tons.
1847-8	..... 51,716
1850	..... 100,000
1864-5	..... 147,000
1865-6	..... 275,000 (a very fine season)
1866-7	..... 215,000
1867-8	..... 210,000 to 215,000 tons expected.

This statement, which is taken from the published accounts, settle the question of the ability of the beet-sugar manufacture to stand a competition with the produce of the tropical countries, and to beat it too in the contest. The reason for such a result is obvious, when we consider the disadvantages under which the latter labours. In the first place the cane ripens all at once, and must be cut and pressed immediately, otherwise it will become too ripe; and it is equally necessary that the juice should be instantly boiled down, otherwise it will ferment and become acid, which would materially lessen the product. The cane contains about 18 per cent. of saccharine matter; but the difficulty in expressing the juice is such, that not more than 10 or 12 per cent.† is obtained, a considerable portion of it being frequently in a crystallized state in the cane, which cannot be extracted by pressure. The necessity for thus concentrating the manufacture into a short space of time renders the harvest labour expensive, and the average cost of all the West India Islands (English) in 1847 was 21s. 3d. per cwt., classed as follows: Jamaica, 22s. 7d.; Guiana and Trinidad, 25s.; Barbadoes and Antigua, 15s. 4d.; St. Kitts and Grenada, 16s. 2d.; St. Vincent, 19s. 2d.; Tobago, 17s.

There is no doubt that a great improvement has been effected in the West Indies since 1847, by the introduction of

the new processes employed in the beet-sugar manufacture in Europe, and that the expenses have been greatly reduced thereby. The following statement was given in before the Committee as the actual result of the sugar crop of that year :

Cost of cultivating and manufacturing the crop of sugar of 1847 .....	£3,390,086
Freight to Europe, at £4 per ton .....	638,228
Brokerage, insurance, landing, &c., at £3 per ton .....	478,671
	<hr/>
	£ 4,506,985
159,557 tons of sugar sold .....	4,336,930
	<hr/>
Loss.....	£ 170,055

If to the expense of cultivating and manufacturing we add the loss of 15 per cent. of the produce, on the voyage to Europe by drainage, on the sugar, and 20 per cent. on the molasses, with the frequent loss of a hoghead of sugar by its bursting from fermentation (in which case the contents are pumped up with the bilge-water), the result, as above stated, is accounted for; and, whatever improvements the West India planters may have introduced into the manufacture the last few years, the beet-sugar manufacturers will still have the advantage of being on the spot of consumption, with that of being able to make an immediate return of their capital, without the losses and expense attending a long voyage. In order to show the difference in this respect between colonial and beet sugar, we give the following account of the manufacture and product of the latter on a large scale. It was communicated to Professor Sullivan, of the "Museum of Irish Industry," by the manufacturers, Messrs. Serret, Hamoir, Duchesne, and Co. (the largest manufacturers of beet-root sugar in Valenciennes), about three years after the statement of the West India planters, as given above:

## EXPENSE.

	F.	£
Cost of 60,000,000 kilos. (or 61,607 tons) of beet at 16 <i>l.</i> (12 <i>s.</i> 11 <i>d.</i> ) per 1,000 kilos. (nearly a ton)...	960,000 ...	38,400
Cost of desiccation ... ..	300,000 ...	12,300
General expense of manufacture ...	690,000 ...	27,300
	<hr/>	
	F. 1,950,000	£78,000

## PRODUCE.

Estimating the per-centage of sugar obtained at only $\frac{1}{4}$ the 60,000,000 kilos. would give 2,700,000 kil. (about 2,700 tons) of sugar, which, duty deducted, would be worth about 1 <i>l.</i> (or 9 <i>d.</i> ) the kilo. of 2 <i>l</i> 1 <i>s.</i> 3 <i>d.</i> or about 40 <i>s.</i> per cwt. ... ..	2,700,000 ...	108,000
Molasses, estimated at 3 per cent., 1,800,000 kilos. (or 1,800 tons) at 5 <i>s.</i> (4 <i>s.</i> 0 <i>d.</i> ) per 100 kilos. (or 220 <i>l</i> bs.) ... ..	90,000 ...	3,600
Residue, or pulp, at 1 <i>l.</i> (9 <i>d.</i> ) per 100 kilos., 6,000,000 kilos. (or 68,933 tons) ... ..	60,000 ...	2,400
	<hr/>	
	2,850,000	114,000
Deduct expenses (as above) ... ..	1,950,000	78,000
	<hr/>	
Net balance to cover rent, taxes, &c. F. 900,000		£36,000

Any one acquainted with the present method of manufacture of beet-sugar will know that the present product of crystallized sugar averages much more than  $\frac{1}{4}$  per cent.; that, in fact, it is nearer 7 per cent., and in some cases 8, and even 9 per cent., while the expense of manufacture is considerably reduced. Experience has also taught the growers that the quantity of saccharine in the beet may be increased by a certain and more careful cultivation. This has been a main object of the continental growers and manufacturers, and they have succeeded beyond their expectations. One of these (M. Koechlin, a Bavarian) has even obtained as much as 17  $\frac{1}{2}$  per cent. of saccharine, which is quite equal to the average quantity in the sugar-cane, and, if generally attained, would settle the question of competition with the latter, if the Governments did not interfere. If Messrs. Serret, Hamoir, and Co., had

obtained that per-centage in the above account, instead of 4,500 tons they would have had 10,781 tons of sugar and molasses.

There is no reason whatever for the supposition that this manufacture should not succeed in the United Kingdom as well as on the Continent. The question, in point of fact, rests wholly with the agriculturists, and whether it would pay them—not as well as wheat, for it must not for a moment be supposed that the cultivation of sugar-beet would supersede that of wheat—but whether selling the roots would pay them as well as consuming them on the farm, or as growing common man-gold or turnips for the purpose? To this question we shall now address our attention.

It is notorious amongst agriculturists that the cultivation of root crops, of whatever kind, for fattening purposes is only profitable as a raw material in the manufacture of manure, and that, as such, they cannot be valued at more than eight or ten shillings per ton; the profit on the cattle not being greater than the capital employed in their purchase, and the necessary expenses of attendance, &c., entitle them to. It is a well-known practice with many, if not most, of the farmers, in making up their accounts, to charge the expenses attending the cultivation of the roots to the cattle and sheep account, without reference to or calculating their estimated value; and thus, whatever profit or returns may accrue from them is included in the increased value of the cattle. This mode of lumping together in one amount the proceeds of animal and vegetable produce is not, it is true, a strictly business-like process, but it helps the farmer over a difficulty, which is more likely to result in error than to give a correct view of the profit and loss of such species of produce. For instance, if the turnips or mangolds are consumed by cattle under cover, and the dung from that consumption is valued at ten shillings per ton of roots, how much ought to be deducted from this for the straw used in their conversion, for they cannot be made into manure without straw? The estimate of ten shillings per ton must necessarily be an arbitrary one, because it is impossible to calculate the effect of the manure upon the crops to which it is applied, the success, or otherwise, depending as much, or even more, on the season than on the manure.

This question of the value of a root crop is perhaps the most intricate and perplexing in the whole routine of agricultural accounts; and the plan of charging the cost of those crops to the debit of the cattle account is the readiest and most conclusive plan of dealing with them, however illogical the system may appear in the eyes of a regular accountant. By it, the roots being given to the cattle, which are charged with the expenses attending their cultivation and other expenses, the profit or increased value of the cattle will constitute the value of the roots relatively with whatever other food—as hay, cake, straw, &c.—may be given to them.

But it is otherwise with the crops of roots grown for sale, as in the case of the sugar-beet, for which a debtor and creditor account of the most exact and conclusive kind may be kept, and the profit or loss exactly defined. This, like all agricultural crops, will depend on the season in a great measure, but quite as much on the treatment they receive. Some of the more intelligent beet growers on the Continent have succeeded in raising fifty, sixty, and even more, tons per hectare (2*a.* 1*r.* 35*p.*) of small roots; and one farmer who cultivated them by planting instead of sowing produced 105 tons per hectare, or about 4  $\frac{1}{2}$  tons per acre, which, at 18*s.* per ton, would pay far better than any crop of cereals that can be grown. Even at the moderate produce of from 15 to 20 tons per acre, the return of from £13 10*s.* to £18 would, when the smaller expenses are taken into the account, be quite as remunerative as a cereal crop. For instance, if we take a crop of wheat at an average rate of 4 quarters per acre, and 50*s.* per qr., which may be reckoned the extreme average, of both produce and price, we have 4 quarters of wheat at 50*s.* = £10. If, again, we take the produce of sugar-beet at 15 tons per acre, and 18*s.* per ton, we obtain 15 tons at 18*s.* = £13 10*s.*, leaving a balance in favour of the beet of £3 10*s.* per acre. The wheat requires nearly twelve months to mature and harvest, besides sometimes the loss of a previous season by a fallow. The beetroot matures in five or six months, requiring no fallow, and can be turned into money as soon as it is raised, without any additional expense except cartage from the land. We have estimated the average produce of beet at the lowest

that is grown in this country; and the probability is that, with extra care, it may be raised to 20 or 25 tons per acre.

But it is not in competition with wheat or any other grain that we wish to place the cultivation of the sugar-beet; for it has been found that around Valenciennes and other places where the manufacture of beet-sugar is carried on, the produce of wheat has largely increased, both in respect to the breadth of land sown and the yield per acre. So much, in fact, has the soil been improved by the culture, that wheat and beet are alternated with the very best effect, and the farmers have increased in wealth wherever the system has been introduced. The land is manured for the beet-root, but requires none for the wheat, and the cleaning of it when under that crop is an excellent preparation for the wheat. The cultivation, therefore, of this grain is rather promoted and increased than diminished by the introduction of the manufacture of beet-sugar. The question of comparative advantage to the farmer lies between the value of the root crop consumed by cattle and its sale to the sugar manufacturer, with the option of buying the residue at a fair price for fattening purposes, for which it is better fitted than the entire root, being all solid food divested of much of the water it contained, and still holding from 4 to 5 per cent. of saccharine matter. This is another feature of the question which we have not yet touched upon, but it is a very important one. On the Continent the sale of the residue is a regular branch of the manufacture; but in some of the large manufactories in Germany and Austria it is consumed by the animals—which to a large extent are pigs—on the premises. The composition of the pulp is thus stated by Mr. Sullivan, in two cases, as worked at the Laboratory of the Museum of Irish Industry.

A SPECIMEN OF NO. 2 PULP CONTAINED, AS IT CAME FROM THE PRESS,

	100.000	

Dr. Sullivan has given a tabular statement of forty specimens of the composition of the beet-root in its natural state. We shall give analyses of the best and the worst of these as examples:—

BEST.

Water ...	80.623
Sugar ...	13.185
Nitrogenous substances ...	2.970
Cellulose ...	1.326
Pectine, organic acids, fat, &c. ...	0.960
Ash ...	0.936
	100.000

WORST.

Water ...	93.054
Sugar ...	3.127
Nitrogenous substances ...	1.047
Cellulose ...	0.827
Pectine, organic acids, fat, &c. ...	0.735
Ash ...	1.210

100.000

The average of these in sugar is 8.155 per cent., and when the amount of other solid substances in the residue are added to the sugar it contains, it will be seen that it amounts to as much fattening matters as the root in its natural state. This, in fact, is Dr. Sullivan's opinion as expressed relative to the tables of the analyses of both as given above. "A comparison," he says "between these numbers and those given at page 40 of the preceding report, leads to the singular result that pulp is as nearly as possible of the same value as raw beet, one constituent merely replacing another. In the raw beet the sugar forms the preponderating constituent belonging to the class of non-nitrogenous substances capable of being assimilated by animals. In the pulp, a considerable part of the sugar is replaced by pectine, which fills the same office as food."

These analyses are very important as settling the question of the feeding properties of the pulp after the juice has been extracted. The proportion of pulp in beet, according to the same authority, is about 30 per cent. of the entire weight, so that nearly one-third of the crop of beet is thus returned to the land when purchased by the grower. The difference in the amount of sugar in the two specimens given above is to be accounted for by the difference of soil, manure, and general treatment of the crop. But where these important matters are more strictly attended to, with the view to the cultivation of the root expressly for manufacturing purposes, there is no reason to doubt that the result will be quite as good and as uniform as in France or any other part of the Continent.

We have hitherto confined our remarks on the working of the beet-sugar manufacture to that of France; but it has extended itself into all the continental states with quite as much success as in that country, as the following statement will show:

QUANTITY OF BEET-SUGAR MANUFACTURED IN GERMANY.

The Zollverein.

	Tons.
1864-5 .....	170,000
1865-6 .....	185,000
1866-7 .....	200,000
1867-8 .....	estimated at 165,000

Austria.

1864-5 .....	85,000
1865-6 .....	70,000
1866-7 .....	90,000
1867-8 .....	estimated at 95,000

Russia.

1849-50 .....	1,620
1851-52 .....	3,833
1854-55 .....	5,424
1855-56 .....	4,924
1856-57 .....	6,364
Coarse sugar, not included above .....	6,087
1858-59 .....	15,000
1866 .....	80,000

The most extensive sugar-works of the Zollverein are those at Waghhausen, in Bavaria, at which 80,000 metrical quintals (of 2 cwt. each) are manufactured annually; and the number of men in constant employment is 500, whilst during the busy season it is increased to upwards of 2,000. This establishment belongs to a company, and is a very flourishing concern.

In Russia the beet-root sugar manufacture is continually increasing; and new and extensive works are rising up in every part of the country. Enough sugar is now manufactured to nearly supply the whole population. The consumption has been more than doubled within the last few years, and now averages two pounds per head of the whole population. There is an abundance of capital; and new companies are continually being formed, and are much encouraged by the Government, whose main commercial policy is to exclude as

much as possible foreign importations, by rendering the country independent, manufacturing as much as possible at home, and imposing heavy duties on foreign productions.

In Austria, sugar-making from beetroot and distilleries from the potato are conducted on a large scale in the aggregate, although in the first instance the sugar-works were small. The introduction of both these industrial employments took place in 1830, and between that time and 1840 115 sugar-works were erected; but it was found not to yield a profit on a small scale, and many of them were consequently stopped, reducing the number at work to 108, although some larger establishments of the same kind had been erected. Still, the manufacture is not so extensively carried on as in France, the agricultural distilleries, of which there are upwards of sixteen thousand in Austria, being preferred. A few years since, the extent of land employed in cultivating the beetroot was about 32,000 acres, producing about nine tons of beet per acre, or, in round numbers, 300,000 tons. This yielded 438,380 cwts. of crystallized sugar, 182,000 cwts. of molasses, and upwards of 30,000 tons of *megasse*,\* or residue. The latter is employed in feeding cattle and swine. Upwards of 20,000 persons are employed in this manufacture during the five winter months, when all agricultural work is suspended in Northern Germany. It is therefore so far a great boon to the rural population; and as Austria has no sugar colonies, such an indigenous manufacture is beneficial to the country at large.

It was feared when the beet-sugar movement first commenced in France that the occupation of so much land as it would require would materially interfere with and reduce the cultivation of cereal produce and the rearing of cattle. So far, however, is this from having been the result, that the product of both has largely increased—in proof of which, an inscription is to be seen over the gate of Valenciennes to the effect that since the introduction of this manufacture into that and the surrounding districts the production of wheat has increased from 122,500 quarters to 143,180, and the number of cattle reared and fattened from 700 to 11,500. Not only so, but wherever this branch of industry has been introduced, the agriculturists have become wealthy; while, by the employment of so many hands during the five winter months (which were formerly idle ones, or nearly so), the condition of the rural populations is greatly improved; and this is the case throughout the continent wherever the manufacture has been carried on with spirit.

No reason or cause whatever exists to prevent this manufacture from succeeding in the United Kingdom as well as on the Continent, if entered upon with spirit by the manufacturer, and well supported by the agriculturists. This latter, in fact, is the pivot upon which the question of success chiefly hinges; and when the farmer becomes convinced that his interest is concerned in its promotion, and that instead of its *impoverishing* it will *enrich* the soil, and afford him a living profit and something beyond it, and that he can fatten more stock with the residuum of the roots with a portion of artificial food than he now does, there is no fear that he will hesitate to second the enterprise with his utmost efforts, esteeming those who engage in it as the farmers' true friends.

### THE GRASS.

The grass, the grass, the beautiful grass,  
That brightens this land of ours,  
Oh, why do we rudely let it pass,  
And only praise the flowers?  
The blossoms of spring small joys would bring,  
And the summer-bloom look sad,  
Were the earth not green, and the distant scene  
In its emerald robe not clad.

Then sing the grass, the beautiful grass,  
That brightens this land of ours;  
For there is not a blade by nature made  
Less perfect than the flowers.

\* This will give not more than ten tons of roots to every ton of saccharine matter, or one ton of crystallized sugar to every 13½ tons of roots, and one ton of molasses to about 33 tons of roots. This is a very large proportion of saccharine, amounting to nearly 10 per cent. The account is official.

The grass, the grass, the feathery grass,

That waves in the summer wind,  
That stays when the flowers all fade and pass

Like a dear old friend, behind;  
That clothes the hills and the valley fills,

When the trees are stripped and bare:

Oh, the land would be like a wintry sea,  
Did the grass not linger there.

Then sing the grass, the bonny green grass,

That to all such a charm can lend;

For 'tis staunch and true the whole year through,  
And to all a faithful friend.

The grass, the grass, the bountiful grass,

Oh, well may the gift endure,

That never was meant for creed or class,

But grows for both rich and poor.

Long may the land be rich and grand

Where the emerald turf is spread;

May the bright green grass, when from earth we pass,

Lie lightly o'er each head.

Then sing the grass, the bountiful grass,

That stays like a dear old friend;

For whatever our fate, it will kindly wait,

And serve us to the end.

### SONG OF THE HAY-MAKERS.

BY ELIZA COOK.

The noontide is hot, and our foreheads are brown,

Our palms are all shining and hard;

Right close is our work with the wain and the fork,

And but poor is our daily reward.

But there's joy in the sunshine, and mirth in the lark,

That skims whistling away over head;

Our spirits are light, though our skins may be dark,

And there's peace with our meal of brown bread.

We dwell in the meadows, we toil on the sod,

Far away from the city's dull gloom;

And more jolly are we, though in rags we may be,

Than the pale faces over the loom.

Then a song and a cheer for the bonny green stack,

Climbing up to the sun wide and high;

For the pitchers and rakers, and merry hay-makers,

And the beautiful Midsummer sky.

Come forth, gentle ladies—come forth, dainty sirs,

And lend us your presence awhile;

Your garments will gather no stain from the burs,

And a freckle won't tarnish your smile.

Our carpet's more soft for your delicate feet

Than the pile of your velveted floor;

And the air of our balm-swathe is surely as sweet

As the perfume of Araby's shore.

Come forth, noble master, come forth to the field,

Where freshness and health may be found;

Where the wind-rows are spread, from the butterfly's bed,

And the clover bloom falleth around.

Then a song and a cheer for the bonny green stack,

Climbing up to the sun wide and high;

For the pitchers and rakers, and merry hay-makers,

And the beautiful Midsummer sky.

"Hold fast!" cries the waggoner, loudly and quick,

And then comes the hearty "Geo-wo!"

While the cunning old team-horses manage to pick

A sweet mouthful to munch as they go.

The tawny-faced children come round us to play,

And bravely they scatter the heap;

Till the tiniest one, all aspent with the fun,

Is curled up with the sheep-dog, asleep.

Old age sitteth down on the hay-cock's fair crown,

At the close of our labouring day,

Add wishes his life, like the grass at his feet,

May be pure at its "passing away."

Then a song and a cheer for the bonny green stack,

Climbing up to the sun wide and high;

For the pitchers and rakers, and merry hay-makers,

And the beautiful Midsummer sky.

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

## THE GENERAL MEETING OF THE MEMBERS.

The usual meeting of the members of the Society was held on the Saturday in the show week on the ground. Lord Berners presided in the absence of the Duke of Richmond, who was unavoidably detained in town.

On the motion of Lord Bridport, seconded by Lord Cheham, a vote of thanks was accorded to the Mayor and Corporation of Leicester for their reception of the Society. On the motion of Col. Kingscote, M.P., seconded by Mr. Sanday, a vote of thanks was also passed to his Highness the Viceroy of Egypt for the gold cup presented by his Highness for competition among the makers of agricultural implements. Mr. Shuttleworth moved and Mr. Millward seconded a vote of thanks to the railway companies for the facilities given by them in the conveyance of stock and implements to the show. Mr. Brandreth Gibbs moved and Mr. Cantrell seconded a vote of thanks to the local committee for their exertions to promote the success of the meeting.

Sir G. JENKINSON wished to call attention to a speech made by Mr. C. S. Read at the Chamber of Agriculture dinner on the previous evening—a speech which he thought was very detrimental to the interests of the Royal Agricultural Society, although he did not suppose that Mr. Read would have said what he did without considering that he had some good ground of complaint. Mr. Read said in substance that the tenant-farmers of England were not in sufficient numbers supporters of the Society, and he was not surprised at this being the case, considering the treatment they received and the management of the council. Mr. Read further said that the council was a close borough, that how he got in he did not know, and how soon he got out he did not care. Mr. Read also said that members of the council voted against the interests of the agricultural classes instead of supporting them. These were heavy charges for a member of the council to make, and as they would go forth to the world it was very important that they should not remain uncontradicted or unexplained if possible.

Mr. SAMUEL SIDNEY was not prepared to endorse all that had been said by Mr. Read. It could not be said that the council was a close borough, as there had been a constant increase in the number of members representing the tenant-farmer interest. Since the Society met at Salisbury it had made changes of a very important character; but although it had done that, he believed in the opinion of persons much more influential than himself, there was a great deal more change wanted. Nine years since, when the council elected a secretary and an editor of the *Journal*, they disappointed the whole agricultural body; and as the council was now about to elect another gentleman, who was to combine the offices of secretary and editor, it was to be hoped that the same mistake would not be repeated. One of the most important things the council had to do was to publish its *Journal*, which ought to be one of the most popular hand-books of the kind in the kingdom. The other day the chairman of the *Journal* committee—a body which he (Mr. Sidney) thought ought not to exist at all—expressed himself perfectly satisfied with the *Journal*. It was an old saying, that every monkey admired its own mannikin (laughter) and this must be the case with Mr. Thompson, for although in the *Journal* there were occasionally valuable papers; still, as a general rule, the papers were unquotable. Mr. Thompson might be valuable as a railway director, and would probably be a member of the next House of Commons; but he did not know how to make the *Journal* of the Society useful and interesting at the same time. However, Mr. Thompson made the person who was under him do as he liked, and that was one reason why the *Journal* was dull. Mr. Acland, who also exercised a great deal of influence in the management of the *Journal*, took a double first-class at Oxford; but if Mr. Acland had his living to get as a writer, nobody would think of employing him; for, although his language was good, and his grammar perfect, he wanted style. The Society would not get a first-rate man to be editor of its *Journal* if he was to have a *Journal* Committee sitting over him. Such a com-

mittee might be useful in a financial point of view; but no newspaper, no journal, no magazine had ever succeeded except it had been managed by one man: he might receive suggestions, but he must not be under orders. To pass on to another committee—the implement committee—presided over by Colonel Challoner. When Colonel Challoner founded the Society, thirty years since, he rendered an essential service; but if the implement committee now comprised gentlemen who kept pace with the spirit of the age, we should not have such absurdities as the Royal Agricultural Society giving prizes for swing-ploughs—an implement which, if not abandoned, ought to be abandoned, being false in mechanical principles. If the council proceeded on the idea that what was right in 1839 would do equally well in 1869, it would not command the confidence of the agricultural world. He found, with regard to the appointment of secretary and editor, that some members of the council wanted a perfect gentleman, of good standing, who could speak all the European languages, who was a good chemist, who had a knowledge of mechanical science, who was a first-rate accountant, and who could write a considerable number of articles himself. Now, it was the editor's business to draw out from the tenant-farmers of the United Kingdom all the good solid information he could get. Talented contributors might be obtained, and it would be good policy to engage such gentlemen, and pay them at a good rate—twelve or fifteen guineas per sheet—instead of, as now, filling up the *Journal* with bits and scraps and translations from a French paper, which nobody cared to read. The Society had flourished on aristocratic support; but, if it were to go on, it must turn to the tenant-farmers to swell its numbers. If the Society did not advance, it could not live; and the merely having a good show, and making a good deal of money, was not promoting the cause of agriculture.

Mr. T. WILLSON said when he and the mayor of Leicester attended a meeting of the council, as members of the local committee, the treatment they experienced quite justified him that the council was a close borough. Lord Lerna was kind enough to say that he and the mayor might sit in the committee-room; but, afterwards, a member of the council came out and peremptorily ordered him and the mayor out of the room. He (Mr. Willson) hoped that the gentlemen of the Manchester local committee would be allowed to sit in the council-room, if they were not allowed to vote. He did not think the council ought to dismiss the secretary without calling together the members of the whole Society; for he had never seen a secretary who had performed his duties better than Mr. Hall Dare. The members of the Society ought to determine whether that gentleman was to be turned out to satisfy a clique.

Mr. MASFEN, of Wolverhampton, generally supported the course taken by Mr. Read. Mr. Willson had just used the word "clique." Now he (Mr. Masfen) thought a clique was bad in everything, certainly it was a bad thing in the Royal Agricultural Society of England.

Col. KINGSOTE, M.P., thought the Society was much indebted to Sir G. Jenkinson, for calling attention to Mr. Read's speech, as unless the accusations of Mr. Read were answered, the Society could not be otherwise than damaged by them. But his firm belief was that those accusations could be fully met, and that it could be shown that there was no favour or affection in the election of members of the Council. He believed Mr. Read had stated that no tenant-farmer, who was a member of the Council, could bring forward any motion without being immediately set on one side. He (Col. Kingscote) had attended most of the Council meetings; he could only remember one proposition which had been brought forward by Mr. Read, and his belief was, that it was not rejected. As regards the election of members of the Council, nothing could be fairer; the country was mapped out into districts, to each district so many members of the Council were appointed; and supposing that any member of the Council died or went out in rotation, another member was immediately appointed from that district. Although there might not be many tenants,

farmers on the Council, still there were many independent farmers upon it—men like Mr. Bowley, Mr. Torr, Mr. Randall, Mr. Turner, Mr. Edmunds, Mr. Sanday, and Mr. Riden. Tenant-farmers could not be expected to come up to London from Northumberland or for long distances; the Society must have upon the Council gentlemen who, if not actual tenant-farmers, were still practical agriculturists. He entirely denied that the Council was a clique. It was to be regretted that tenant-farmers did not subscribe more generally to the Society; but it must be remembered that they subscribed to county local shows which had sprung from the Society.

Col. CHALLONER said it had been insinuated that the Council was a self-elected body; but the fact was that the Council was elected by members of the Society (Cries of "No, no"). He repeated it; the members of the Society elected not only the council, but the trustees, the president, and the vice-president. At the general meeting the Council recommended such and such names in a list, but if any one present wished to strike out a name from the list; or introduce another, he could do so. With regard to himself, it was not his fault, but his misfortune that he had now done the work of the Society for twenty-four or twenty-five years. He was quite willing to resign his post as chairman of the implement committee; his resignation would save him many a journey to London when he would willingly be doing something else. If Mr. Sidney went into Scotland and abused swing-ploughs, he would be abused himself. The management of the Society could not have been so very wrong for the last twenty years, seeing how it had increased in numbers, in capital, and in everything else.

Mr. GEORGE TURNER, as a tenant-farmer and member of the Council, denied that his suggestions had not been listened to; on the contrary, they had been received with as much attention as any made by the Duke of Richmond or any one else.

Mr. SEWELL READ, M.P., said some of his remarks appeared to have been totally misconceived, for when he had attended the meetings of the Council, any suggestions, which he had made had always been received with the greatest courtesy, and carried a fair amount of weight with it. He had not said either that tenant-farmers were not represented on the Council; but what he did say was, that the Council was a close borough. He now learnt for the first time, from Col. Challoner, that the members of the Council were elected by the great body of the members. But there was a gentleman, Mr. Robert Smith, of Exmoor, who was excluded from the Council the other day; and who excluded him? Why the Council, not the general body of the members. If the members of the Society were to take an active interest in the election of the Council, voting papers must be sent round to them. What he said on the previous evening was not uttered in anger, but in sorrow, and in endeavouring to account for the small number of members of the Society, which some years since had 7,000 members, while it had now rather less than 6,000.

Mr. H. S. THOMPSON said if members would not attend the general meetings how could they know how the business of the society was carried on? He maintained that the election of the members of the council was conducted upon sound principles, for the society did not want to have upon its council a certain number of farmers living within 50 or 60 miles of London; what it wanted was to have members of the council selected from all parts of England, so as to get at the opinions of every district. And this was what was now done. As to the diminution in the number of members mentioned by Mr. Read, it was rather apparent than real, as it arose from the greater stringency with which the payment of arrears was enforced: there never was a time when the society had more subscribing members. As to the general result attained, no one who looked round the show-yard could say that the management had been very unsuccessful. It was always open to any member to make suggestions to the council, and any suggestions so made would be decided on its merits. As to the management of the *Journal*, it came out twice a year, and was intended as a work of reference, containing the best articles which could be obtained upon different subjects; while a paper which came out once-a-week, was read and then torn-up, was naturally made as light and amusing as possible; there was a distinction between the two classes of literature. And where was the work which contained more sterling articles than the *Journal* of the Society—giving as it did articles from the pens of such writers as Lawes, Playfair, Way, and Curtis?

Lord BRIDPORT thought that Mr. Read had not made himself acquainted with the rules of the Society. As to the complaint made by Mr. Willson of a want of courtesy, he (Lord Bridport) must disclaim all knowledge of Mr. Willson and the Mayor of Leicester having been ordered out of any room.

The discussion was continued by Mr. May, Mr. Bottley, Mr. Calves, and Mr. Shuttleworth, the latter gentleman remarking that twenty-three out of the fifty members of the council were farmers, while three were implement-makers, so that it could not be said that the farmers or implement-makers were not represented on the council; moreover twelve out of fourteen suggestions recently made by the implement-makers had been carried out by the council.

Mr. WILLSON moved that voting-papers should in future be sent out.

Col. CHALLONER said, by the terms of the charter of the society the management was entirely confided to the council. Any suggestion would, however, have due consideration.

After further remarks from Mr. Masfen, Mr. Thompson, Mr. H. B. Caldwell, Col. Kingscote, M.P., and Mr. Baldwin,

The CHAIRMAN expressed his belief that the more the management of the society was discussed the better it would be found to be.

Thanks were then voted to the Duke of Richmond for his conduct as president during the past year, and a similar vote having been accorded to the chairman of the day, the proceedings terminated.

## COUNTY FINANCE.

The Select Committee appointed to inquire into the present mode of conducting the financial arrangements of the counties in England and Wales have agreed to the following report—

1. That it appears by the evidence given before the Committee by persons residing in various counties of England—

1st. That the administration of the financial business of counties has been hitherto conducted by the magistrates with a general regard to economy.

2nd. That, nevertheless, a desire prevails on the part of county ratepayers to place the county finance more directly under their own control, by means of elected representatives to be associated with the magistrates in the expenditure of the rate.

3rd. That this desire appears to arise generally from considerations of public policy, but also, in some instances, from a want of sufficiently detailed information as to county expenditure.

2. That this Committee, judging from the general tenour of the evidence, believes that a system of financial control, of which the following shall form the principal provisions, would be satisfactory to the ratepayers:—

1st. That the boards of guardians in counties should elect representatives, who should be admitted to take part in and vote at all meetings of magistrates held in such counties for the consideration of questions of county expenditure.

2nd. That in cases where a Poor-law Union is situated in more than one county, a representative may be elected in each county where there are at least six parishes or townships; and that where there is a less number, the parishes or townships should be added to the adjoining union for the purposes of election.

3rd. That committees appointed for the purpose of managing the finances of separate departments should consist of an equal number of magistrates and representatives, each body electing its own members of such committees.

3. That this Committee is of opinion that the mode of keeping the public accounts should be uniform in all counties; that a detailed statement of them should be published in some newspaper of the county at least once in each year, and be forwarded to each board of guardians; and that some officer should be appointed for the audit of public accounts.

4. That the clerk of the peace of every county shall be elected by the court of quarter sessions,

## FOREIGN AGRICULTURAL GOSSIP.

The report of the Marseilles Docks and Warehouse Company just issued states that the movement of wheat at Marseilles, which began to make itself apparent in the autumn of 1866, acquired a great extension in 1867. In 1867, the quantity disembarked on the quays of the Arene and Napoleon basins was 74,372 tons, to which must be added 46,425 tons which arrived by steamers, making the total quantity dealt with in the company's docks last year 120,797 tons. Almost the whole of this wheat was conveyed from the company's quays to trucks, and out of the whole 120,797 tons, only 33,874 tons went into warehouse. The movement of wheat has continued on nearly the same large scale during the current year. Thus from January 1 to March 31 this year there were imported into the docks 13,987 tons by steamers, and 43,823 tons by sailing or steamships, making a total of 57,810 tons. It is not perhaps generally known that the French gentlemen who attended the Leicester meeting of the Royal Agricultural Society did so as a delegation from the Society of Agriculturists of France. So long since as June 9, M. Drouyn de Lhuys addressed the following letter to the Duke of Richmond, President of the Royal Agricultural Society: "Paris, June 9, 1868.—Monsieur le Duc,—The Society of Agriculturists of France, which has been just founded at Paris, has chosen me for its President. It is in this capacity that I have the honour to-day to address myself to you, desiring as we do at the outset of our labours to enter on friendly relations with the eminent Royal Agricultural Society of England. We shall be happy, Monsieur le Duc, to follow in your steps, and all the communications which you may be good enough to address to us will be of great value. Our object is the same; we devote our common efforts to the prosperity of agriculture. It is, then, with eagerness that we shall seize the approaching occasion to strengthen that inviolable bond which already unites us, by sending our delegates to the great exhibition of July 12th to July 21st, prepared by the Royal Agricultural Society of England. The secretary-general of the Society of Agriculturists of France will have the honour to send to the secretary-general of your society the names of our delegates; and we feel assured, beforehand, of the sympathetic reception which they will meet with in your great meeting.—I have, &c., DROUYN DE LHUYS." The Duke of Richmond replied as follows: "London, June 12.—Monsieur, I have the honour to acknowledge the receipt of the letter in which you are good enough to inform me that you have been appointed president of the Society of Agriculturists of France. Permit me to assure you that the society over which I have the honour to preside will be very happy to send you all possible communications, and to put itself entirely at the disposal of those members of your association who may be able to attend our meeting at Leicester in July.—I have, &c., RICHMOND." The delegation which eventually attended the Leicester meeting was composed as follows: M. Drouyn de Lhuys, president of the new society; Comte Charles de Bouillé, the Comte de Courcy, M. Grandean, M. Lecouteau (secretary-general), M. Bonna, M. Tiersonnier, and the Vicomte de Tocqueville; M. Decauville, jun., was attached to the commission in the capacity of secretary. Some other delegates had been designated by the council to attend the meeting, but personal engagements detained them at home at the last moment. Several members of the society also proceeded to Leicester as simple visitors, the list of these latter including MM. Albaret, Pillet, Gérard, the Marquis de Leizer, &c. While the Society of Agriculturists of France has been thus establishing intimate relations with the Royal Agricultural Society of England, it has committees at work preparing programmes for approaching exhibitions. One of these commissions, presided over by M. Hervé-Mangon, has already completed its projects of organization as regards competitions of machinery. The date of the next general meeting of the society will be fixed by the council as soon as possible, but it will not take place until after the close of the now nearly-completed French harvest. The society is obtaining new members from day to day. Thus in the fortnight ending July 14th, 18 founder members, 23 ordinary members, and 21 delegate members caused their names to be inscribed upon the

society's books. The society now comprises, taking into account the new adhesion, 10 perpetual members, 1,069 founder members, 129 ordinary members, and 30 delegate members—making a general total of 1,238. The subscriptions which have been received have been paid over to the account of the treasurer of the society, Baron James de Rothschild, and have been employed in the purchase of French funds. In consequence of the disappearance of the rinderpest, the not very oppressive restrictions and precautions which remained in vigour on the eastern and northern frontiers of France, as well as on the coasts of the Channel, have been entirely removed. Two customs establishments alone in the département of the Bas-Rhin have been excepted, and continue to apply the system of preliminary inspection as to the sanitary condition of cattle imported from abroad. These exemptions have been made since the localities in question constitute the most easy, the most direct, and the most commonly followed communications with the most distant parts of Germany.

It appears that the President of the Republic of Chili, considering that the date (Dec. 15, 1868) originally fixed for the opening of the Agricultural Exhibition of Santiago did not afford European exhibitors sufficient time for the delivery of their products, has issued a decree postponing the opening of the Exhibition to April 1, 1869.—A man whose long career was entirely devoted to agriculture, M. Charles Leleuvre, member of the superior council of agriculture, and honorary president of the Lille Agricultural Committee, has just died at Paris.—The state of the French crops for the current year and for the current month is summed up by the *Journal d'Agriculture Pratique* as follows: "Wheat generally good; barley and rye of good quality; oats leaving something to be desired; straw small in quantity; vines inducing the best hopes; beetroots and potatoes suffering from drought, like most of the products still in the ground; hops, beautiful; flax, of mediocre quality; hemp, very fine; tobacco, of rather bad quality in the Nord, the Dordogne, and the Landes."

**THE FARMERS' FRIENDS.**—A good deal has been said in North Devon of Mr. Moore-Stevens as a farmers' friend. We hope that our yeoman friends at Tiverton who have been thinking so highly of him in this character will read the report of the cause of Stevens *versus* Copp, tried at the assizes yesterday. These are the facts of the case in brief: A small farmer, with a long family, occupies a leasehold farm in Little Torrington. Mr. Stevens is the owner. The farm is held on a lease for lives, and the lease contains an extraordinary covenant, that in the event of the occupier committing an offence against the game laws he shall forfeit his lease! The defendant, in November last, was, by the Torrington Bench, in the presence of the plaintiff, convicted of an offence against the game laws, or of using a gun to kill game without having a game licence. On this conviction the plaintiff now grounded an action of ejectment for breach of covenant, and a verdict was given for the plaintiff, with leave to the defendant to move the Court above upon all points that could possibly arise on the evidence. The learned judge who tried the case seemed surprised at the stringency of the covenant. The lease is old, and there was no evidence adduced to show that the defendant was aware of the existence of this remarkable covenant. The lease was running when Mr. Stevens bought the land. He is a barrister, and on looking over the lease would soon see the nature of its covenants. We will not remark on this extraordinary case, which is brought before the county by "A Farmers' Friend"; but it appears to us, that Chambers of Agriculture should give the case some consideration, and leaseholders should be admonished to look to their leasehold obligations, lest they find themselves overtaken with law suits which may turn them out of house and home. Farmer Copp is permitted by the verdict to take the case to London, and get the opinion of "the Court above" on all the points of law involved in this intricate case. But how is a tenant-farmer to carry on that kind of warfare? —*The Western Times*.

## CALENDAR OF AGRICULTURE

This is the general harvest month in Britain, as all kinds of grain crops are cut and carried, except in high situations, and in northern latitudes, in which the next month is the general harvest. Wheat is best cut by hand and sickle, and tied into sheaves, and placed in shocks of twelve sheaves in each. Barley and oats may be cut by scythe, and lie for some days in the swathe before being tied into sheaves. When dry, carry the grain quickly, and build the crops into ricks or lodge them in barns. In cases of very level and smooth surfaces of grounds which bear straws of thickly-planted culms of medium height, the crops are very conveniently cut by machinery of great modern ingenuity with very beneficial results. But the great variety of crops and surface grounds over the kingdom may ever confine the use of machinery in cutting grain crops to the favoured cases of level grounds, and upright standing crops of a thick plantation and a medium height.

Cut peas by the hand sickle, and lay the crop in small heaps, which are turned over frequently, and carried, when dry, into ricks on the top of other grains, in order to have a light pressure, or very well over a shed open below, as in a sloping ground. Thatch the ricks quickly, as the culms offer no defence against rains. Thatch must be in readiness, and ropes prepared.

In order to save the expense of thatching the ricks of grain, and to secure the crops from damage by a quick protection from rains, the ricks must stand along the sides of a railway, over which is thrown a roof of zinc or corrugated iron, resting on iron pillars. A light waggon will convey the unthrashed grain along the railway to the end of the barn, where a travelling carrier will convey the sheaves to the scutching machinery on the third floor, from which the grains winnowed from the chaffs fall to the second floor, to be riddled, and thence descends to the ground floor, to be bagged for sale; at the same time the straws on the third floor are cut into short lengths by knives impelled by the steam-power, and carried as litter over the cattle yards by a travelling web that rests on temporary legs, and shifted in any direction. This arrangement would be a mighty convenience in harvest, and also in the manufacture of the crops. The saving of thatching by hand will soon repay the cost of railway and its cover.

Cut grain crops before a dead ripeness has produced a flinty condition of the pickles; the straw will be better fodder, the sample of grain is more delicate, and the flour will be finer. The husks being filled, the grain will soon become hardened after being cut. Barley is thinner in the skin, and suitable for malting.

Finish the cleaning of all green crops, and earth-up potatoes with two deep furrows of the double mould-board plough, drawn by two horses, walking in distant furrows, with a maintree of five feet stretching between them. The cultivation of po-

tatoes requires deep working in every operation; the crop grows below ground, and demands encouragement in that quarter more than plants that are produced on the surface. A week may elapse between the two furrows of earthing up; pull by hand any tall weeds that may afterwards arise.

Spread pulverized lime on clay fallows; cover by harrowing; lay the dung on the land, and spread evenly over the surface, and plough it under, both operations going on together, or as nearly as possible following each other. The cinders of lime in a small size may be spread over the surface of the land, and ploughed under at a time previous to the dung being applied on the finished fallowing of the ground; the bursting of the cinders in the moist under-ground will evolve much heat to penetrate the mass, increase its temperature, and diffuse much benefit from the damp exhalations that are produced. The land may be formed into drills by one furrow of the common plough; the dung spread along the hollows, and covered by splitting the ridglets with one furrow of the plough. This method will cover the dung very completely, and is less costly than ploughing; but a cross-harrowing may be required, to level the drills for the seed furrow. The lime is well applied in the above method, and the farmyard dung is well covered by the drilling of the land.

Give to horses and cows in the yards an ample supply of vetches, which will now be the green food of the farm, and of much nutriment from the pods being seeded. Provide litter in abundance; the manure produced will pay almost any cost.

Fold sheep on bare spots of poor pastures; go on with draining on wet lands; turn over any earthy compost; burn peaty and vegetable substances for ashes, to be used by the drop drill; keep the liquid tank filled with earthy materials to be saturated; carry to the pit refuse matters of every kind.

Keep the draft ewes on good pasture, in order to get the animals fattened; put ewes to the ram for early lambs. The lambs of the year must be favoured with good keep. Some farmers, who have not winter food, nor the means of fattening, sell at this time the lambs and draft ewes.

Sow on well-prepared grounds, in a warm sheltered situation, the seeds of drumhead cabbages, kohl rabi, savoy, and brocoli, for plants to be used next spring. Sow in the end of the month rye and winter vetches for early use, as the first green food of the farm. The seeding must be a large allowance, not under four bushels on an acre, as it never can be too thickly done for feeding crops.

Straws may be reduced into dung during summer as largely and of the same quality as in winter, by providing a constant supply of green food to horses and cattle and milch cows in the

yards, and by cutting the straws into short lengths by the thrashing machinery, to facilitate the saturation of the culms by the urinary fluids, and the covering in the land as dung. Juicy food is required for the secretion of fluids, and in a constant abundance, and the yards must be concreted in the bottoms, to hold the watery elements. Vetches can be arranged to supply the green food of the farm from the beginning of

May to the end of September, and the plant is most fitted for the purposes of food and dung, from the large quantity of juice for the animal, and in the refuse leaves and stems decomposing into an earthy residuum. No plant yet known can be compared with the vetch in these respects; and no man will ever do much in farming who does not provide and apply manures with a constant, a lavish, and an unsparing hand.

## CALENDAR OF GARDENING.

### KITCHEN GARDEN.

**Turnips.**—Sow the Early Stone or Dutch varieties, or Red American—a new introduction. Sow the main crop in drills, with an inch or two of good manure, and a pint of bone-dust to each barrow, three inches directly beneath the intended rows; and these drills ought to be struck in ridges formed by taking some of the earth from the spaces between them. Choose an open plot of land outside the garden; for turnips rarely prosper within it. Hoe and thin the plants as they grow, till at last they stand at about nine inches apart, and above two feet from row to row.

Sow, in the first week of the month, the main crop of next year's Early York cabbage, or Hill's Dwarf; about London and in its latitude, from the 7th to the 10th; a week earlier for colder and more northern localities. Water the drills before sowing, if the weather be dry. The early part of the second week is to be preferred for sowing; but experience must guide in this respect. Some localities require an earlier season—even in July.

Sow winter prickly spinach twice. Choose mellow soil, moderately rich, like that after fresh-dug early potatoes. Nitrate of soda has been proved to be a most fertilising dress, particularly in binding, gritty loams—half-a-pound, scattered over a pole of 30½ square yards, dug in, and the rows a yard apart. Sown as the digging proceeds.

Sow also a sprinkling of French Horn carrot, and Scarlett on shallow soils. Salads and Cress: The Golden or Australian should be added to those in daily use.

**Lettuce:** The Paris and Brockett White Cos. **Radish:** The Wood's Early and French Breakfast, early in the month, and again in the second week or later.

Sow cauliflowers about the 20th, and place the grown plants under glasses or in frames.

The hardier sorts of lettuce, carrots, and onions (White Lisbon) for spring use, and all other vegetables that may have been omitted in July, are to be sown in this month, except the legumes.

Dig up early potatoes. Leave some of the medium-sized tubers of the ash-leaved kidney to lie exposed and green, for seed store. Transplant at various times, according to their size.

Start well-formed plants of cabbage, broccoli, savoy, and Brussels sprouts in the respective varieties, with the exception of savoy, of Early

York, Hill's Dwarf, and Enfield Market, Early White and Winter White, and the Alexandra variety, late and fine, tall and Roseberry Dwarf, with larger sprouts. Incorporate a quantity of good manure with the soil, to which has been added sulphate of ammonia, half-a-pound to the square pole. Coleworts for greens in the same manner, twelve inches apart. Celery for the latest crop about the 20th, in the best varieties of Cole's Crystal White and Williams's Matchless. If the weather be dry, apply water liberally. Never mutilate the plants by cutting the leaves. Earth up former plantings timely and carefully. The spade may be used when the plants are strong, and have already been twice earthed. Propagate sweet herbs by slips and cuttings. Take up garlic, shallots, and onions that are ripe.

Destroy weeds. Leave none to spread the evil by seeding; and at this time a very careful attention is required.

Cut vegetable marrows and cucumbers as they come on, not leaving any to become ripe. Be particular to gather French beans and runners; for if pods ripen, the bearing of eatable pods becomes checked at once. "Gather beans, and have beans," says the old rule.

### FRUIT DEPARTMENT.

**Raspberries.**—Attend first to cut out the brown canes that have borne fruit. Then take away slender, supernumerary, young shoots. Air and sun will thus act upon those six or seven good canes which are left to ripen. Burn the dry canes that are pruned out, and scatter the ashes over the raspberry beds. Some condemn this burning; but we like that the earth receive back, as soon as possible, the inorganic salts thus developed by fire.

"Spur-bearing" trees on espaliers should be regulated very early, by cutting back or snapping the wandering breast or spur-wood, one-third of their length. By snapping, the sap is checked and diverted to the lower buds, while its course is not so fully and suddenly arrested as it is by amputation. The trees are for a time rendered unsightly; but, as all must be cut lower back in a few weeks, that is a mere trifle, if the benefit which has been alluded to be taken as a "set-off."

Apples, pears, and standard trees, or espaliers, are to have spring and summer growths curtailed, excepting the leading shoot, to cause the swelling of the fruitful buds at their base.

## FLOWER GARDEN.

Attend to the routine directions that have been often given; and now repot and dress the auricula plants, and pot off seedlings. At the end of the month, transplant or introduce evergreens, particularly if the weather be moist.

Manure must be collected with constant care. Tall weeds will now be grown on roadsides, ditch-banks, and in the borders of plantations, to be gathered at little cost by children and aged persons, cut into short lengths, and laid in the urine

pit, there to be soaked and rotted by suds and fluids. Vegetables singly are best rotted by fluids; but scourings of ditches and roadsides, with a mixture of earths, are best mixed in a dry compost of earths and lime, in which the vegetables are decomposed, forming a manure of quick efficacy and a long duration. The droppings of the dung of animals may be mixed in this earthy compost, or placed in the urine pit, and mixed with the moist vegetables. In either way a manure is produced from two sources, at little cost, and of certain effect.

## AGRICULTURAL REPORTS.

## GENERAL AGRICULTURAL REPORT FOR JULY.

The weather during the past month has been unprecedentedly hot, and almost of a tropical character. Scarcely any rain has fallen in any part of the country, and general complaints of the long-continued drought continue to reach us from all quarters. The country for the most part presents a scorched and blasted appearance, and great evil is resulting from the prevalent scarcity of water. The brilliant weather has, however, had a most favourable influence on the wheat crop, and has brought it to early and good maturity. Cutting commenced early in the month in the southern districts; by the second or third week the harvest was almost general, and, as we write, the majority of the crop has been well got-in; only the scarcity of labour has retarded the harvest operations in some districts. The dry weather has enabled farmers to secure their crops in excellent condition, and the out-turn is everywhere favourably spoken of—the weights per bushel varying from 62 lbs. to 66 lbs. As a rule the quality is excellent—especially of those samples grown in heavy lands, although some of the parcels from the light and gravelly soils are somewhat shrivelled from excessive heat, having been forced into too early maturity. Taking into account the large extra breadth of wheat sown, and the heavy yield per acre when compared with last year, the total crop will be much in excess of that of 1867.

Barley will apparently turn out much better than was expected, although some of the accounts are very discouraging.

We have seen some good yields of oats; but the crop generally is below an average.

The yield of beans and peas will scarcely be equal to last year.

Rarely have harvest operations commenced at so early a date as at the present time, or been conducted under such favourable auspices. Compared with the general run of seasons, wheat-cutting commenced fully a month earlier than usual, and the crop has been carried with much greater rapidity. The recent calculations as to the probable amount of wheat required to be imported will be considerably thrown out, in consequence of the very early appearance of the new wheats. The stocks of old wheat, however, are very light, and a considerable portion of any surplus that may accrue from this present harvest will easily be taken up in replenishing them.

The sale for wheat has been very inactive, and the trade has been in a most uncertain state, as usual at harvest time, when the out-turn of the crops is much disputed. Millers have operated with extreme caution, and only to supply immediate wants. The general tendency of prices has therefore been downwards. The first few parcels of new wheat exhibited at Mark Lane, however, changed hands at extreme rates; but on the arrival of further samples factors were more moderate in their demands, and accepted considerably less money.

Oats have gradually tended upwards throughout the month, owing to the threatened scarcity of animal food.

Barley, beans, and peas have commanded very full prices.

With regard to the root crops the accounts received are extremely unfavourable. The yield of turnips, mangolds,

beets, &c., threatens to be exceedingly small, and there is every prospect of a great deficiency in the supply of animal food throughout the winter.

The hay crop has been secured throughout the country, even at this early period. The yield has proved to be extremely light, although the quality of the produce is fine, and the crop has generally been carried in excellent condition.

There has been a fair inquiry for most kinds of Spring corn, and the quotations have had a gradual upward movement.

There have been heavy importations of oats, but not sufficient to depress prices in the face of the great failure of the hay and green crops.

The stocks of English barley, oats, beans, and peas are nearly exhausted.

The following shows the value of hay and straw in the metropolitan markets. New meadow hay £3 10s. to £5; old ditto £4 to £5 10s.; new clover £3 10s. to £5 5s.; old ditto £4 to £6; and straw £1 10s. to £1 16s. per load. There is still a moderate quantity of last year's hay in stack.

Our advices show considerable discrepancy in the opinions as to the out-turn of the potato crop, but a most disheartening failure seems to have occurred in many districts. This appears to be owing to the want of moisture, which has retarded growth and induced blight.

The fruit crop is early, and is turning out moderately good, although a little rain would have improved appearances. Apples promise well, and those descriptions of fruit which require great heat have, of course, been greatly benefited by the present season.

In English wool there has been very little doing, and holders have shown considerable anxiety to effect sales. Prices, consequently, have continued to give way. The importations of colonial produce have been on an extensive scale, and, as they are likely to be even heavier in future years, they will have a most depressing influence in the value of home produce. The result of this year's clip is very favourable.

The accounts from the hop plantations have been most encouraging, the heat having induced a rapid growth of bine. The burr looks very healthy, and the amount of lice has not been such as to cause any serious apprehensions. The continued drought, however, has induced an attack of red spider, which some smart showers would have remedied. Under these circumstances, the market has been extremely inactive, and holders have been anxious sellers, even at a considerable reduction. The first pocket of new Kent hops has been sold in the Borough at £8 8s. per cwt.

In Scotland, the crops generally are very forward, the cutting of wheat having been commenced in some districts. The yield will be greatly in excess of last season. Barley and oats are not looking very well, and potatoes, as in England, are a partial failure.

In Ireland, the potato crop does not seem to have suffered to the same extent as in the sister island, but the out-turn will be decidedly below the average. Wheat is favourably spoken of, but the harvest operations are not so forward as on this side. The markets generally have been inactive, and the quotations have followed the course of prices in the English markets.

## REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

The present season has been a most unfortunate one for the breeders of live stock. The great heat has caused a heavy deficiency in the supply of water, while the failure of grass and of the green crops has almost prevented animals from being kept in condition at all. The scorched state of the country has caused great difficulty to breeders and graziers, the result of which has been that the stock has been forced to market in a premature and half-fat condition. The Norfolk season closed well, and the first arrivals of beasts from Lincolnshire and Cambridgeshire to the metropolitan market were in fair average condition, but the long-continued drought soon commenced to tell on the quality of the stock, which is now being sent to market before it is nearly ready for the butcher. These beasts, being inferior, have changed hands at a further reduction in value, but the few really good beasts on sale have commanded late rates. From Scotland the arrivals have been small, and the quality has not been so good as usual. Really prime Scots and crosses have changed hands at 4s. 8d. to 5s. per 8lbs., but the general prices realised have been below that figure. The supplies of English beasts have been in excess of the same period last year, while the number of foreign animals exhibited has fallen off.

Very large numbers of sheep have been on sale, having been forced to market in consequence of the want of pasture and water. The quality of most breeds has been inferior, and all but choice animals, which have been very scarce, have changed hands on lower terms. Prime Downs and half-breeds have realised 4s. 8d. to 5s. per 8 lbs.—the latter being an extreme quotation.

Full average supplies of lambs, of which the production this year appears to have been heavy, have come to hand. The demand has been fairly active, and the quotations have been supported, say 5s. to 6s. per 8 lbs.

Large quantities of calves have been on sale, the importations having been unusually heavy. The animals have been of fair quality, but no change of importance has taken place in the quotations, which have ranged from 3s. 6d. to 5s. per 8 lbs.

Pigs have been in fair demand on about the terms lately current, the top figure being from 4s. 2d. to 4s. 4d. per 8 lbs.

The large quantities of stock now being forced to market in consequence of the protracted drought, will have a serious effect upon our future supply of food, and serious apprehensions are beginning to be expressed on the subject. The hay crop has turned out a failure, and the turnips, mangolds, &c., show very little prospects of any remunerative return. The supply of animal food for the winter is, therefore, likely to be only moderate.

The total supplies of stock exhibited in the Metropolitan Cattle Market have been as follows:—

	Head.
Beasts ... ..	24,312
Sheep and Lambs ... ..	195,250
Calves ... ..	3,938
Pigs ... ..	1,360

### COMPARISON OF SUPPLIES.

	Beasts.	Cows.	Sheep.	Calves.	Pigs.

Veal .....	4 0	5 6	...	3 6	5 0	...
Pork .....	3 4	4 6	...	3 2	4 4	...

Owing to the intensely hot weather, the supplies of meat on sale at Newgate and Leadenhall Markets have been only moderate, and the trade has been subject to much fluctuation. The general course of prices, however, have been as under. Very little foreign meat has been on sale:—Beef, from 3s. to 4s. 4d.; mutton, 3s. to 4s. 6d.; veal, 3s. 10d. to 4s. 8d.; lamb, 4s. 6d. to 5s. 4d.; pork, 3s. to 4s. 6d. per 8lbs. by the carcase.

## EAST GLOUCESTERSHIRE.

The well-known and generally accepted proverb, "A dry summer never brought a famine in England," will afford great consolation in this trying year. Last year there was abundance of food for the inferior animals, but a scarcity for man. This year the reverse appears likely to be the fact; for although wheats on light soils would have been greatly improved by more moisture, the heavy-land crops are most promising. If we remember rightly, the summer of 1844 was much drier than the present, and yet the crop of wheat was good. So far, then, as "breadstuffs" are concerned, we think there is nothing to fear. Wheat cutting has commenced on some Talavera and other early kinds, and the "whitening for harvest" is rapidly going on everywhere. Of barley we cannot speak so hopefully; for although on highly cultivated lands the early planted crops are good, yet all the accounts we hear of the later sown crops are decidedly bad, and it seems doubtful if the long drought has not entirely spoiled a large breadth both of barley and oats, together with the clover and grass seeds sown therewith. The beautiful showers which came on Sunday last may refresh the young clovers, &c., but can hardly be of much service to stunted and sun-burnt cereals. Beans are very short of straw, and badly podded; but we have seen them worse; the winter variety are best. The earlier kinds of peas were tolerably good, and have already been harvested; the later crops variable, and some worthless. Vetches do not promise well for seed, although the crop for fodder was good. Hay is all secured in first-rate order; the ricks are small of meadow hay, but clovers and artificial grasses were quite an average crop, and as a large quantity of old hay remains on hand the prospect for the winter is not so bad. Potatoes are sadly injured by drought, and very small; the little ones will have to be used for human food, and cooked in Irish fashion—"with their jackets on;" but what will become of the pigs is difficult to say. Happily there is no disease. The early-planted mangolds are tolerably good; late ones bad. Swedes are scarce, and generally looking very sadly; they cannot be a crop. Turnips we have none, but the land is well prepared, and should we be blessed with a soaking rain within the next three or four weeks we should not despair of a crop of the quick-growing varieties. The grass lands are frightfully burned up, and water is very short, which has driven a large quantity of fat and half-fat stock into market; consequently trade has been dull, and prices muted lower than for years past. The corn markets, too, are from 16s. to 18s. per qr. lower from the highest point. The land is still exceedingly hard, and six strong horses are not unfrequently seen with difficulty moving a plough. The ploughmen, too, get a good shaking. Flies and other insects seem unusually abundant this season, but swallows and martins remarkably scarce. We are sorry not to hear their usual cheerful twitter on our houses, and must strongly deprecate

the practice of those uncomfortably clean housewives who insist upon having "the dirty things' nests" removed from the overhanging eaves. We would give every encouragement to these and other harmless useful birds and friends of man, wisely sent by a beneficent Creator as a wholesome check to the mischievous insect tribe.—July 15.

#### MID-KENT.

"O dear! do you think there is any hopes of rain?" is the remark usually made when one person meets another. And some gloomy reply follows, with details of the suffering inflicted on certain things, and the still more serious aspect of the future. Yet now and then we meet with some who look more cheerfully at things; and their recollection of 1818 and 1826 recalls periods not by any means so bad as some would make them appear just now, although those seasons resembled the present one very much. But it is not my purpose to speculate further into the future than is warranted by the condition of things at present; and in reporting how they stand now, I may say our pastures, which were once green, have passed through the brown stage, and are now almost bleached white, with only a little vestige of a green tint under trees or by the sides of ditches, that it is marvellous how the sheep and cattle eke out a living. The sheep, I may observe, are doing well where it is not too bare, but in most cases some additional food has to be given to the cattle. We being fortunate in having a large proportion of last year's hay can get on pretty well, but those who have to depend on the crop of the present year must be badly off indeed, and their number is legion; and small as the quantity was, it does not appear likely to be supplemented by either the straw or Lent corn or green crops, for even our lucerne seems to quail with the continued heat and drought; clover being still worse; so that green food for present use is out of the question. Thus all our hopes are centred in the hope, which on the whole look well, and promise to be one of the most abundant crops on record, and much earlier than was ever known before; and if all goes on well, we hope this crop will make amends for many of the shortcomings of the year. Fruit, though also earlier than usual, is not so abundant as was expected, in fact in many places it is only indifferent; nevertheless it is a fair paying crop, and its gathering has given employment to much labour that would otherwise have been thrown out of employ before harvest. Now when the latter is going on it is needless to say there is plenty to do for every one, and the hurrying condition of the weather is such that every one having grain ripe is anxious to have it cut and secured as quickly as possible; and at the time I write much has been so secured, wheat especially. Oats and barley will, however, be short in straw, but the sample will be good, and we hope the yield will be more than its appearance at one time looked likely to be. Potatoes, however, will be small, and are now too far advanced towards maturity for rain to do them anything but harm. Mangold in some places looks not amiss, and may yet become a crop; and we have seen a piece or two of swedes that might yet do well if rain came at once, but they are exceptions to the general rule. Of white turnips I may say there are none; I certainly have not seen a single piece that gave the slightest claim to the term "crop." The season, however, is not too far advanced yet for a moderate crop of these, if the future be showery and growing. But those who would be our weather prophets seem unable to tell us what this future is to be, and appearances for rain have been plentiful enough, but none follows, so that we are afraid the present summer will end as it has begun, a Continental or Australian one. And as we have not had quite one inch of rainfall since 29th May, it is easy to conceive the scorched-up condition of vegetation, and what is equally bad, the deficiency of water for domestic purposes, which most likely has not reached its worse yet.

#### AGRICULTURAL INTELLIGENCE, FAIRS, &c.

**BOSTON SHEEP MARKET.**—About 500 fat sheep; but a slow trade was done, at from 5d. to 6d. per lb. Lambs, which were somewhat plentiful, were extremely difficult to quit even at reduced rates.

**BROMYARD FAIR.**—There was a good supply of cow

and calves, which, owing to the scarcity of keep, met with a very dull sale. There was also a large supply of sheep, and these also from the same cause went at very low prices. Pigs were likewise very low in price: few horses on offer, with but little business doing. Altogether trade was very dull.

**BURGH FORTNIGHTLY FAT STOCK MARKET.**—There was a good show, prices being a shade lower than last market, beef ranging from 7s. 6d. to 8s. per stone, and mutton 5½d. to 5½d. per lb.

**CAWDOR TRYST.**—Prices showed a downward tendency; but, in consequence of an anticipated favourable change in the weather, holders of stock generally declined extremely low prices, notwithstanding the scarcity of pasture, and a good many lots consequently remained unsold. Mr. Alexander Frazer sold a lot of two-year-old cross stots at £12 each; Mr. Lawrence bought a lot of two-year-old stots at £13 each; Mr. Duncan Robertson sold a cow for £15; Mr. Macpherson sold two two-year-old queys for £28 10s.; Mr. Robb sold a lot of two-year-old cross stots at £14 each; Mr. Rose sold a lot of two-year-old stots at £16 each; Mr. Maclellan sold a polled quey at £11; Mr. Clark bought a lot of one-year-old Highland cattle at £14 10s. each; Mr. Macdonald bought a lot of two-year-old stots at £13, another lot at £15, and another lot at £18 each; Mr. A. Macdonald bought a fat heifer for £13. In sheep, the following are among the transactions: Mr. Maclellan bought a lot of sheep (dimonts) at £24 5s. per clad score; Mr. Arnott sold a lot of sheep at 22s. each; Mr. Cameron bought a lot of half-bred hogs at 25s. each.

**GRANTHAM FAT STOCK MARKET.**—A good show of both sheep and beasts. Beef 7s. 9d. to 8s. per stone, mutton 5d. to 6d. per lb. Slow trade.

**HORSHAM LAMB FAIR.**—There was not so many sheep penned by about a thousand as there were last year, and owing to the very limited amount of feed in the country, trade was remarkably dull. This year there was between 11,000 and 12,000 sheep; a great many of them were unsold, and for ewes there appeared to be scarcely any inquiry. There were some very fair lambs. Mr. Bird sold about 80 at 28s. per head. Mr. King made 30s. each of a lot. The Messrs. Emery, however, had the crack lot of the fair, exhibiting 300 wether lambs, which took the highest price of the fair, 32s. each.

**KIRTON LINDSEY FAIR.**—A very meagre show of beasts, in which the trade ruled very sluggish; but fair prices were made, considering the long dry season. Hardly any sheep, which were generally neglected. A moderate supply of horses, and a brisk business passing: the prices made ranging as high as £40.

**LEWES FAIR.**—The trade ruled very dull, large numbers being sent home unsold. The highest prices we heard of were 36s. for some wethers belonging to Mr. Kirby, and the highest for lambs 22s., belonging to Mr. Deadman. The number of sheep and lambs was between 14,000 and 15,000, an increase of about 1,000 over last year. Business could only be done at a considerable reduction on the price of last year, in consequence of the scarcity of sheep feed.

**PALDY FAIR.**—Business was stiff, and the prices ruling may be quoted as a shade lower than last year. For black-faced ewes from 9s. to 18s. was got; for wethers from 18s. to 30s. At a late hour a good number of sheep remained unsold. The cattle market was well attended. Unlike the previous day, rain fell heavily at intervals during the day, which seemed to do the farmers' hearts good. The effects on the crops was wonderful. Notwithstanding this, business proceeded very stiffly, and the prices had, if anything, an upward tendency. The figures were 10s. 6d. to 11s. per Dutch stone. The top lot in the market was sold at £20 each.

**READING FAIR.**—Although graziers and dealers offered to dispose of stock cattle at reduced value, few sales were effected. The continued drought has parched the grass land, and green cattle food is scarce, and farmers are unable to sustain stock without the assistance of hay. This year's hay crop being short and the price considerably advanced, stock keepers are constrained to thin out cattle herds, and the country markets are glutted with half-fatted beasts, &c. Dairying cows were in great demand, and large-farmed, well-bred, full milk cows sold at £20 to £24 a head. There was a large show of superior class horses, and animals suitable for heavy draught purposes obtained a ready sale.

**SANQUHAR LAMB FAIR.**—On this occasion the

business done was far short of any previous market. This was, however, looked for, because of the long-continued drought, which is completely baffling rears of stock, and has, moreover, upset the intentions of dealers as well as graziers. The attendance of farmers and dealers was pretty considerable; but, while the former were anxious to sell, the latter were seemingly perfectly indifferent whether they purchased anything or not. Generally, black-faced ewes would be back from 3s. 6d. to 5s.; black-faced ewe lambs, from 3s. to 4s.; black-faced wether lambs, from 1s. to 1s. 6d.; Cheviot lambs, from 2s. to 3s.; half-bred lambs, from 4s. to 7s.; and crosses, from 3s. to 5s. We can only give a general range of prices: Black-faced ewes sold from 11s. to 14s. 6d. The last-mentioned price was obtained for a lot which fetched 20s. last year, and the year before 33s. Black-faced ewe lambs ranged from 12s. 6d. to 16s.; and wether lambs, from 3s. to 8s., and 9s.; Cheviot wether lambs, from 7s. 6d. to 15s.; Cheviot mid ewe lambs, 11s. 6d., and half-bred lambs, from 14s. upwards.

**SHERBORNE FAIR.**—A small quantity of poor stock, and a few pens of sheep; the scarcity of keep and the early harvest-feld keeping back both sellers and buyers. Business was something worse than a drag. A fine pen of good bred down lambs moved off at 14s. a-head.

**ST. AUSTELL MONTHLY MARKET.**—The show of fat cattle was exceedingly good: average price from 65s. to 67s. per cwt. Cows and calves a very small show and dull sale. Mutton, very fine, 6½d. to 7d. per lb.

**ST. BOSWELL'S FAIR.**—For quality of lambs this fair may be considered the principal fair on the Borders, the lambs in most instances being reared on the crack farms of Tweedside and Tiviotdale, and are in most instances three-parts bred. The show this year, owing to the dull state of the other lamb markets, was expected to be a large one; but these anticipations were not realized, the number of head being several thousands less than on the previous year. Notwithstanding the small supply, the numbers appeared quite adequate to the demand, and at the close a number of the best lots, besides inferior ones, left the market unsold. The top price in the market was got by Mr. Fairbairn, who sold his lot at 26s., being 1s. 3d. less than the price he got last year. The fall in the prices generally would run from 2s. to 7s. per head. There was a large number of horses. The attendance of dealers was also large. There was a want of good hunting animals; but there were several good draught animals. For good animals there was a fair demand, but secondary kinds were slow to sell.

**IRISH FAIRS.**—**COOTHILL:** Beeves brought £21 downwards, springers and milch cows £17 down, bullocks and storks £8 down, yearlings £2 to £3; beef 6½d. to 8½lb.; fat sheep 48s. down, lambs 20s. to 25s., wethers and mediums 32s. to 39s. Pigs scarce; bonhams 12s. to 18s. each, slips 55s. to 75s. each, porkers 57s. to 62s. per cwt. The horse fair was small; farmers' nags £8 to £12, cavalry horses £20 to £32 each.—**BALLYRAT:** The prices for cattle rather advanced; calves £2 to £3 5s., bullocks and storks £5 to £8 5s., springers £17 down; beef 6½d. to 8½d. per lb.; fat sheep 49s. down, wethers and mediums 40s. down; lambs 29s. down; mutton 8d. to 8½d. per lb. Pigs scarce; suckers 12s. to 18s., hoggets and mediums 55s. to 70s., fat 58s. to 62s. per cwt. Of horses there was a fair supply; those fit for the cavalry and high-class animals exchanged owners at from £20 to £40.—**CAMLUGH:** Two and three year old bullocks of anything like promise brought from £7 to £12 10s. per head; yearlings £4 to £6 10s.; two year old heifers averaged £8 per head; yearlings £4 to £5; calves £2 to £3 each; strippers £7 10s. to £10 each. The show of sheep was an average, aged wethers scarce, and mutton rated from 5d. to 6½d. per lb. Lambs were freely purchased at from 18s. to 24s. each. Some superior ones went as high as 26s. to 28s. a-piece. Milch cows and springers were in fair supply. The best prices for springers varied from £14 to £10 10s.; secondary and inferior from £8 to £12 16s. per head; milch cows from £9 10s. to £15 per head; store pigs from 36s. to 48s. each; suckers and yearlings from 15s. to 20s. each. No really superior horses. Spring colts of active stepping action fetched from £20 to £30 each, draught horses and long tails to £18, farmers' nags £10 to £16.—**MOUNTMELICK:** Beef fit for the butchers fetched 56s. per cwt. Springers were few, and went from £10 to £16 each. Year old bullocks could be had from £10 to £13 10s., two years old ditto from £7 5s. to

£10, yearlings from £4 to £7, weanlings from £2 to £3 each. Heifers rated at about the same figures. The sheep fair was moderately supplied, and to effect sales the late downward tendency had to be submitted to, especially in lambs. Mutton ranged from 5½d. to 6d. for prime, second-rate 5d. to 5½d. per lb. Lambs from 15s. to 20s., hoggets 28s. to 36s. each. The pig fair was limited to stores and bonnies. Stores brought 40s. to 60s., slips 30s. to 40s., bonnies 18s. to 25s. each.

#### PRIZES AT OVERTON SHEEP AND LAMB FAIR.

The competition was good in all the prize classes, and the premiums were distributed as follow: A cup, value £10 10s., given by the Right Hon. Lord Northbrook, for the best pen of 100 wether lambs, Mr. John Barton, Basingstoke; second, a cup, value £5 5s., given by Mr. George Schlater-Booth, M.P., Mr. W. Lunn, Whitechurch. A cup, value £10 10s., given by Mr. W. W. B. Beach, M.P., for the best pen of wether lambs, Mr. W. Warwick, Worthy. A cup, value £10 10s., given by Mr. Melville Portal, for the best pen of ewes, Mr. John Barton; second, a cup, value £5 5s., given by His Grace the Duke of Wellington, Mr. Schwann, Houghton. A sweepstake of £1 each, with £5 5s. added by Sir Henry St. John Mildmay, for the best ram of any age or breed, Mr. Olding, Ratfin Farm; second, a cup, value £5 5s., given by the Right Hon. the Earl of Carnarvon, Mr. Moore, Littlecot. A cup, value £5 5s., given by the Right Hon. the Lord Viscount Eversley, for the best pen of ram lambs of any breed, Mr. Morrison, Fonthill.

**WATERCOMBE FLOCK SALES.**—The annual ram letting on July 2nd attracted a large company of breeders. Mr. T. Ensor conducted the letting, and nearly 150 lots were rapidly disposed of at unprecedented prices. The highest figure reached was 41 guineas. This was a four-tooth ram, secured by Mr. Olding, of Ratfin Farm, Amesbury. Last year Mr. Olding hired the same ram for £20. A Hampshire breeder (Mr. Hogg, of Cadlands) took a very fine two-tooth sheep for 23½ guineas. Mr. Dowden, of Roke, secured a six-tooth sheep for 18½ guineas. For 20 guineas Mr. S. Symes, of Doles Ash, obtained a four-tooth ram. Mr. R. Genge, of Waterson, obtained four at the prices respectively of 14, 21, 11, and 12 guineas. Mr. Hogg, in addition to the one before-mentioned, took a ram for 13 guineas; Mr. J. Symonds, of Monckton, gave 10½, 16½, 17, and 18½ guineas for rams; Mr. Vincent of Clifton, Yeovil, 10½, 12, and 22 guineas; Mr. Tink, of Wimborne, 11½ guineas; Mr. W. Besant, of Roger's Hill, 10½ and 13 guineas; Mr. Dowden, of Roke, besides the ram previously mentioned, took another at 14½ guineas; Mr. T. Homer, of Emsworth, 18 and 16½ guineas; Mr. Porter, of Wimborne, 11½ guineas; Mr. Buby, Godmanstone, 15 and 18 guineas; Mr. J. Homer, Martinstown, 10½ guineas; Mr. J. Saunders, Muston, 10½ guineas; Mr. W. Chick, Owermoigne, 12 guineas; Mr. Gale, Nottingham, 15 guineas; Mr. Udall, Chaldon, 10½ guineas; Mr. F. Pope, Kingston Lacey, 13½ guineas; Mr. Bartlett, Burweston, 12 and 12½ guineas; Mr. Paull, Isle of Wight, 12½ guineas; Mr. Hodge, Taunton, 12½ and 15 guineas; Mr. Rawlence, Bulbridge, 12 guineas; Mr. Young Bloxworth, 14 guineas; Mr. H. Pope, Preston, 14 guineas. The others were let at prices varying from six to ten guineas. The proceeds of the letting amounted to nearly £1,189, and the rams were taken by forty-six breeders.

**MR. HUMPHREY'S SALE OF HAMPSHIRE SHEEP.**—This sale took place at Oak Ash, when the ram lambs were first disposed of at an average exceeding £16 each. Mr. Rawlence secured one at 60gs., Mr. W. King one at 57gs., Mr. C. Child 56gs., Mr. Ferris 42gs., Mr. Waters 41gs., Mr. Moore 31gs., Mr. Bennett 29gs., Mr. Saunders, of Watercombe, 29gs., and Messrs. Tanner and Galpin, one each at 26gs. The sheep were next disposed of at prices ranging up to 26gs., Mr. Galpin being the last bidder for one at that figure. The yearling ewes were sold at various prices up to 22gs. for the pen of five.

**MESSRS. CORDEROY'S CHEESE CIRCULAR,** (Thursday last.)—The cheese trade here continues to be much affected by the extreme heat of the weather. It is almost impossible to keep the soundest cheese in good condition even in the coolest and best ventilated warehouses, and our customers naturally shrink from adding more than they can help even to the smallest stocks. When the temperature becomes

cooler we look for a fair demand for really prime new cheese (in good condition) at moderate prices. There is nothing in the aspect of our market, or in advices from abroad regarding the make of foreign cheese, to warrant the expectation of high rates, and we trust our friends will act with due caution. Scotch cheese of choice quality (in prime order) will command fair prices. American cheese are only in moderate demand, at 54s. to 60s. for fine to extra; some very prime useful cheese have been sold at 41s. to 52s. The arrivals since our last are 22,511 boxes.

READING CHEESE FAIR was inadequately supplied, and new cheese comes to hand in bad condition, and the prices vary from 50s. to 56s. and 64s. per cwt.

GLASGOW, (Wednesday last.)—The supply of cheese was liberal, 1,900 having been laid down. The warm season being unfavourable for holding, buyers operate cautiously. About 27 tons sold. Old Cheddars 51s. to 58s., new ditto 44s. to 52s.; old Dunlops 48s. to 55s., new ditto 42s. to 46s.; new Skim-milk 19s. to 20s.

CORK BUTTER EXCHANGE, (Friday last.)—Ordinary: first quality 111s. to 108s., second quality 107s. to 104s., third quality 98s. to 95s., fourth quality 93s. to 90s., fifth quality 83s. to 80s., sixth quality 66s. to 63s. per cwt. Mild-cured: first quality 117s. to 114s., second quality 110s. to 107s., third quality 101s. to 98s. per cwt. Repacked and dairies, 41; 3rds, 4ths, 5ths, and 6ths of kegs 4s. per cwt. less. Currency—ordinary butter 10s. per cwt. less, mild-cured 10s. ditto, sponged butter 2s. ditto.

#### ENGLISH WOOL MARKET.

CITY, MONDAY, July 27.—There is a better feeling in the market for English Wool, holders having shown less disposition to force sales, and prices are rather firmer; there is, however, very little doing for export.

CURRENT PRICES OF ENGLISH WOOL.		s.	d.	s.	d.
FLEECES—Southdown hoggets.....	per lb.	1	3	1	4
Half-bred ditto .....	"	1	4	1	5
Kent fleeces.....	"	1	3	1	4

Leicester ditto .....	"	1	3	1	3
Sorts—Combing .....	"	1	0	1	6
Clothing .....	"	1	2	1	6

BRADFORD WOOL MARKET, (Thursday last.)—The general tone of the market this morning is quiet, although since our last report some rather considerable purchases have been made. It is now, however, near the end of the month—a time when people don't care to enter into many new engagements. Then the quietness in the cotton market and the sluggish demand for German yarns, taken together with the large stock of wool in the market, prevent anything like a general activity. The transactions that have taken place have generally been by the large consumers, who share with the staplers a growing confidence in the value of wool. The extreme firmness of most of the principal holders, leading them sometimes to ask a fraction more money, is itself a proof that they are looking forward to enhanced prices when the market shall have become a little relieved of the heavy stocks now pressing upon it.—*Bradford Observer*.

BRAMPTON SECOND WOOL FAIR.—The Cheviot wool ranged from 1s. 1d. to 1s. 3½d. per lb., a slight increase upon that of last year. Upwards of 6,000 fleeces were disposed of before night.

DONCASTER WOOL MARKET, (Saturday last.)—We had not more than 100 sheets brought to market this morning, the August wool fair being now near at hand. In consequence of that fair, on the 5th August, there will be no wool market next Saturday. A good demand was experienced for all that was shown to-day, and the whole was well sold up at the close of the market, prices remaining quite firm—viz., all-hogg 42s. to 44s., two-thirds do 38s. 6d. to 40s. 6d.; half-hogg 33s. 6d. to 39s. 6d., all-ewe 32s. to 35s. 6d.

GLASGOW WOOL MARKET, (Saturday last.)—A large business has not been done in this market during the week, but a better feeling prevails as compared with the week previous. The announcement of the public sales has in some measure restricted operations, but rates remain extremely firm. Laid Highland is in fair demand, and laid Cheviots meet with a ready sale. White Cheviot and half-bred hoggs are in request, whilst white Highland is all but neglected.—*F. H. M'Leod*.

JEDBURGH WOOL FAIR.—There was a pretty good attendance of buyers and sellers. Cheviot wool brought from 32s. 6d. to 35s., half-bred from 34s. 6d. to 36s. 6d. Messrs. J. Dun and Co. bought blackfaced from 15s. 6d. to 16s.; Mr. Scott (Whitton) sold his clip of half-breds at 36s. 6d.; Mr. Hedley (Stobbs) sold his clip of Cheviot at 35s.; Mr. Stevenson (Keeldar) got for his clip of Cheviot 35s.; Mr. Swan (Bush) got for his half-bred and Cheviot 36s.; Mr. Turnbull (Midburn) got for half-bred 34s. 6d., with a 6d. referred up; Mr. Telfer (Wolfehopelee) got for his Cheviot clip 34s.; Mr. Simpson (Boughtrigs) sold his clip of Cheviots at 35s.; the Gowanburn clip was sold at 35s.; Mr. Logan (Carrout) sold his clip of white Cheviot at 33s. 6d.; Mr. Smith (Templehall) got for half-bred and Cheviot 34s. 6d.; Mr. Snaith (Blakhope) sold his clip of hoggs' at 35s. 3d.; the Otterstonelee clip brought 32s. 6d.; Mr. Mein (Broomhills) sold half-bred at 36s.

LEEDS (ENGLISH AND FOREIGN) WOOL MARKETS, (Friday last.)—The bulk of the English wool is now in the hands of the manufacturers and staplers, and there does not seem much probability of change in price for some time, especially as orders are not being given out freely for either yarn or pieces. There is a fair consumption of colonial and other wool, but scarcely equal to the supply. A large sale at Antwerp last week of South American wool, which showed a decline of from 10 to 15 per cent. on prices obtained there last May.

LEICESTER WOOL AND WORSTED TRADE.—Prices of both wool and yarn remain the same, with dull demand. Leicestershire wool rallied slightly last week—say ¼d. per lb.—some purchases having been made by Yorkshire buyers.

LEWES WOOL FAIR.—At the dinner, which took place at the White Hart hotel, the chair was taken by G. Darby, Esq., of Marklye. On the removal of the cloth, the chairman declared the fair opened. Mr. Filder announced that he had sold his wool, 800 fleeces, to Mr. Alfred Adams, at 15½d. Mr. Goring offered his wool, 400 fleeces, to Mr. Breach at 16½d. Mr. Breach: "I will give you two guineas a tod." Mr. Goring: "How much a lb. is that?"—"15½d." The chairman, amidst great amusement, proposed that they should toss up whether Mr. Breach should give 16½d. or 16d. It was agreed; the chairman tossed the coin, and Mr. Breach, guessing wrong, had to give 16½d. (roars of laughter). Mr. Paxton (to Mr. Adams): "530 ewes and 308 tegs at 15½d." Mr. Adams: "I'll give 15d."—"I'll take it" (cheers). Mr. John Verrall offered 1,520 fleeces at 16½d. Mr. Breach: "I'll give 16d." (accepted). Mr. Ellis, of Beddingham, sold 2,110 fleeces to Mr. Breach at 16d. Mr. Cane, in returning thanks, offered his wool to Mr. Breach at 16d. (accepted). Mr. Farncombe offered 970 ewes' and 340 tegs' to Mr. Adams at 15½d. Mr. Adams offered 15½d. (accepted). Mr. Cane offered Mr. Leigh's wool, 600 ewes and 200 tegs, to Mr. Breach at 15½d. (accepted). Mr. Tickner sold his wool to Mr. Breach at 15½d. Mr. Evans sold 500 ewes and 200 tegs to Mr. Breach at 16d. Mr. Lovegrove, steward to R. Wilson, Esq., sold 100 fleeces to Mr. Breach at 16d. Mr. P. Gorrings sold 332 ewes, 256 tegs, and three rams, to Mr. Legg at 15½d.

SANQUHAR WOOL FAIR.—There was a large attendance and a considerable amount of business was done. The prices for blackfaced wool ranged from 12s. 6d. to 14s., and Cheviot wool from 26s. to 30s., 28s. being the average.

ST. BOSWELL'S WOOL FAIR.—There was an excellent feeling in the wool market, and prices were considered by sellers 6d. to 1s. up from Dunse. There was no doubt but the tone of the wool market was greatly improved, and a large number of clips sold. Among the lots sold were the following: Mr. Fleming (Craigsford-mains) sold his clip of all-hogg at 40s., and all-ewe at 33s.; Mr. F. Tait (Lindean) sold his clip of half-ewe and half-hogg at 36s. 3d.; Mr. Tait (Venchen) sold his clip of more hogg than ewe at 37s.; Mr. Short (Humbledon) sold his clip of half-and-half at 36s. 3d.; Mr. Waller (Ammerside-law) sold his clip of half-and-half at 36s. 6d.

THE NORTHUMBERLAND AGRICULTURAL SOCIETY.—MEETING AT CORNHILL.—The annual show this year was, in respect of the number of entries of all kinds of stock and implements, the best the society has ever held. The entries were nearly two hundred more than at any previous show, and the number of visitors was also

very large. Amongst the shorthorns, some of the aged bulls would have cut a very good figure even at Leicester, and the same remark may be made as to at least half a dozen of the cows. The young bulls were equally good in quality, though few in numbers. The cows, indeed, surprised many, who never anticipated finding so good a show in Northumberland. Still Mr. Booth sent nothing, having preferred to take Grantham on his way from Leicester to Wetherby. The Leicesters were particularly good, and it is hardly necessary to say that amongst the Cheviots were to be found some of the finest animals in Northumberland. The black-faced sheep were most characteristic specimens, the heads especially being perfect pictures. The show of horses was very good, in respect both of quality and number. The five-year-old hunters, as a whole, were an exceedingly good lot, and with no less than 27 entries. The winner was the celebrated bay mare Lady Derwent. The pigs were few in numbers, but in every respect first-class animals. The number of implements was very large. With the exception of one, this department contained no novelty of importance. The exception was Norton's now famous pump. The Duke of Northumberland presided at the dinner.

**WAYSIDE GRAZING.**—At the quarterly meeting of way-wardens for the Wingham division, held at Eastry, Kent, the subject of wayside grazing came on for discussion. It seems that the practice is pursued to a considerable extent throughout the district, much to the inconvenience of the farmers, whose occupations in a great measure are unprotected by hedge or fence, which renders the nuisance more irksome. Measures have, from time to time, been taken to reduce the number of cattle thus fed, and an order issued by the Board, that all animals found grazing upon the highways, not in charge of a person, and tethered, would be impounded. At the meeting on Thursday, however, the chairman announced that, by a recent decision in the Court of Queen's Bench, all highway boards had the power to prohibit the grazing of cattle along the roads, under any circumstances, the only exception being where there existed a right to common or waste land. He read the case, which was an appeal against a conviction by the Hertfordshire justices, who held that the offence of ranging had been committed, even though the cattle were tethered, as they were not upon the road for the purpose of transit from one place to another. The chairman, in announcing that the judges upheld the conviction, said the settlement of the question was of great importance to farmers throughout the country, and he suggested that printed notices should be circulated throughout their extensive district, warning persons against continuing the practice—this was ordered to be done.

## POTATO MARKETS.

### BOROUGH AND SPITALFIELDS.

**LONDON, MONDAY, July 27.**—These markets are fairly supplied with potatoes. On the whole, the trade has ruled steady, at about late rates. The import into London last week consisted of 72 packages, 473 cases, 40 baskets Boulogne; 2881 baskets Rotterdam; 864 boxes, 99 tons Barleux; 19 barrels, 6 bales, 179 sacks, 36 casks, 250 bags Dunkirk; 220 boxes 8 tons Cherbourg, and 77 tons St. Malo.

English Shaws	...	7s. 0d. to 8s. per cwt.
Regents...	...	6s. 0d. to 9s. "
Jersey	...	6s. 0d. to 8s. "
French	...	6s. 0d. to 7s. "

**COUNTRY POTATO MARKETS.**—**BARNSELY** (Saturday last): Kidneys 18s. to 20s. per load, or 5lbs. for 6d., round ditto 15s. to 16s. per load.—**DONCASTER** (Saturday last): Not a large supply of potatoes at market, and these were selling at from 1s. to 2s. per hamper above the rates of last week. Kidneys 8s. to 8s. 6d. per five-peck hamper, round potatoes 7s. to 8s. ditto.—**MALTON** (Saturday last): Potatoes a still trade, dealers only buying for table wants, and there being too much uncertainty for speculation. Retail 1s. to 1s. 4d. per peck. Crop small, but very sound.—**MANCHESTER** (Saturday last): Cheshire 14s. to 22s., Ormskirk 20s. to 20s. per 262lbs.—**YORK** (Saturday last): This market, both with regard to supply and prices, was much the same as the previous week. Kidney potatoes fetched from 1s. 1d. to 1s. 2d., and round ones 11d. to 1s. per peck.

## HOP MARKETS.

**BOROUGH, MONDAY, July 27.**—During the latter portion of the past week a better demand has prevailed in our market at last quotations. Reports from the plantations, although somewhat conflicting, are on the whole less favourable. In parts of the Weald of Kent and Sussex drought and attacks of red spider are more complained of, while in Mid and East Kent and Worcester the grounds are generally progressing well; rain, however, appears to be very much required. European reports are also less favourable. Bavaria and Bohemia are doing well; but the French and Alsot districts appear to be almost parched up. New York advices to the 8th inst. report no change in the market.

Mid and East Kent	.....	£3 10	.....	£4 15	.....	£5 12
Weald of Kents	.....	3 10	.....	4 0	.....	4 15
Sussex	.....	3 0	.....	3 5	.....	3 15
Farnham and country	.....	4 0	.....	4 15	.....	5 12
Yearlings	.....	2 10	.....	2 16	.....	3 0
Bavarians	.....	2 16	.....	3 0	.....	3 10
Belgians	.....	2 14	.....	2 18	.....	3 5

**WORCESTER HOP MARKET, (Saturday last).**—Considering the continued absence of rain, the hop grounds of the district have during the past week made satisfactory progress. The drought has done injury, which is now evidenced from the blind lateral shoots put forward, more particularly on light soils with gravelly bottoms, and by the Jones' plant, which stock shows a want of vigour, that at many places the crop can only be what is termed "a top one." Let it be understood that we look for a full yield on the average; but caution our friends in receiving the reports of some writers, who have predicted an overwhelming crop this year. The result of the growth will be much influenced by the weather during the next few weeks. Irrigation would undoubtedly prove beneficial, causing the young hops to swell out to a full size; otherwise the fruit will be dwarfed in growth, and further would tend to cheek red and white, which at places spreads; also lessen the ravages of the red spider. In early gardens, exceptionally, full-grown hops may be gathered; but ours is only now being generally developed, so that we cannot expect picking to be in full operation for a month or five weeks yet. This market is most barely supplied with stock, business being much checked by planters' indisposition to accept ruling prices.

## COVENT GARDEN MARKET.

**LONDON, SATURDAY, July 25.**

Fruit, both home-grown and foreign, continues to be largely supplied. Abundance of West India pines may also still be had. Kent alberts are coming in in very good condition. Potatoes run small in size, and prices for them are advancing. Cauliflowers and other vegetables are still showing the ill effects of the continued dry weather. Flowers chiefly consist of orchids, pelargoniums, fuchsias, mignonette, and roses.

### FRUIT.

	s. d.	s. d.		s. d.	s. d.
Apples, $\frac{1}{2}$ bushel	4 0 to 5 0		Lemons, each	4 0 to 5 0

Bruges	...19 0 to 20 0	Hamburgh	...17 0 to 19 0		

## REVIEW OF THE CORN TRADE DURING THE PAST MONTH.

A very early harvest has come upon us, as might have been expected from the long course of brilliant sunshine and almost unprecedented heat. Clouds have often gathered, and here and there heat drops and slight showers have fallen; but patches of green have become quite a rarity, and some fears for the future supply of water and provision for cattle have naturally sprung up. A heavy fall of rain in the midst of harvest labour might do more harm than good, as though there is happily a fair prospect of a good wheat year, there is no surplus to spare on any other grain, which has all more or less suffered by the long drought. Much new wheat has already been sent to market, both in London and the country, the quality and weight above the average of years; but the yield will vary from a scanty produce on some light soils, to a great abundance on the deep well-farmed loams and heavy lands. 66lbs. is no uncommon weight this year, though many samples scarcely reach to 62lbs. The first parcel of Talavera brought the extreme price of 78s. on the second Monday; but equally good wheat could have been bought at 63s. on the last, and 60s. can now scarcely be depended upon, general accounts being so favourable. But with plenty of it, should it turn out that we have it, England has long ceased to grow enough for its inhabitants, and with a decline of 20s. from the highest, 8s. to 10s. of which must be placed to account of the present month, we may yet see some reaction. If the rain so long deferred should make up for lost time in quantity and continuance, a rise of 10s. on all fine dry samples would soon be the consequence; and as we are about one month early, we ought to have 13 months' provision on the ground to meet our coming wants with the ordinary imports. Spain has suffered from drought, and other southern countries, even France, partially, which country, like ourselves, was pretty well cleared out; and then prices in Paris are now so much above our own, that we may ere long find French orders in London. Belgium, London, and parts of Germany are yet above us, although for future delivery prices from the latter are low, and Hungary—that vast European emporium—is said to have 10 to 15 per cent. above the produce of last year. American accounts differ materially. The first reports were favourable to a large yield; but the last make this very doubtful, the South, and some land in the West as well, being reported as having suffered by heat and other casualties. In a very little time we shall be able to form better estimates of our future supplies, and the necessities of other places; but let us be thankful that the dread of high prices and scarcity has passed away, and the world now has a prospect that its teeming millions will all again be fed from the fields by the kindness of Providence. The following rates were quoted lately at the several places named: White wheat at Paris 70s., red

63s., white at Bordeaux 65s., wheat in Belgium to 69s., white Zealand in Rotterdam to 70s., Holstein at Hambro' 63s., Saale 64s., red at Cologne 57s., at Berlin 63s., ordinary mixed at Dantzic 63s. (there being no fine left), red at Mannheim 57s.; the range of prices for red wheat at Pesth, in Hungary, 36s. to 50s.; No 1. spring wheat at New York 50s., No. 2 48s. per 480lbs., spring wheat at Chicago 1 dollar 84 cents (47s. 4d. per 480lbs.), at Milwaukee No 1 1 dollar 90 cents (48s. 4d. per 480lbs.).

The first Monday in Mark-lane opened on very scanty supplies of English wheat, but with large arrivals of foreign. Very few samples appeared during the morning on the Essex and Kentish stands. Some picked parcels of red realised former rates; but to sell freely, less money would readily have been accepted. Millers, however, preferred to hold back, in expectation of yet lower rates. Foreign was a very slow sale—indeed, hardly anything was done; and low sorts were fully 1s. per qr. cheaper. Floating cargoes were very dull, at unaltered rates. Considerable variety was evinced in the different country advices this week. Croydon was full-priced, and many places only down 1s. per qr. Others receded 1s. to 2s., as Hull, Louth, Market Harborough, Chichester, and Banbury. Many were 2s. to 3s. per qr. lower, as Bury St. Edmunds, Dunstable, Melton Mowbray, Market Rasen, Rotherham, Lynn, Mansfield, and Thirsk. Liverpool was 3d. per cental dearer for white on the week, but 2d. cheaper for red samples. The Saturday's advices noted a general decline of 1s. to 3s. per qr. Edinburgh made no change in fine qualities; but Glasgow was 6d. per boll lower. Dublin and several other places in Ireland noted no change.

The second Monday had a few more English samples noted in the weekly returns; and there was a heavy supply from abroad. Very little was exhibited on the Essex and Kent stands; but a sample of new Talavera appeared, weighing 64lbs., and was sold at a very high price (78s.) to a town miller, for immediate use; but old qualities remained dull, at a decline of 1s. to 2s. per qr. Foreign also tended further downwards, without transactions, unless in retail at 1s. less money. Floating cargoes were little in demand, and barely supported previous values. The heat increasing in the country to a tropical degree, and dull accounts coming continually from London, with the prospect of very early gatherings generally, prices universally gave way about 1s. to 2s.; and in a few instances, as at Sleaford, this was exceeded; but so scarce were white samples at Liverpool, that their value was again increased equal to about 1s. per qr. Saturday's advices were generally in keeping with the previous country reports, most being down 1s. to 2s., and some 3s. per qr. Edinburgh was in calm, and

Glasgow again down 6d. to 1s. per boll. Dublin and other towns in Ireland remained dull, at nominally the same prices.

On the third Monday there were only short English supplies, but large foreign arrivals continued. More samples of new were exhibited from Essex and Kent—say about 600 qrs.; but, even with these, the entire show of English was very limited. Old was, however, down about 2s.; and sales of the new were made at moderate rates, the best 65lbs. per bushel Talavera not exceeding 70s. 6d., and some very good 64lbs. rough chaff 68s. In foreign very little was doing. Some middling Dantzic brought 64s.; but generally holders would readily have accepted a decline of 1s. to 2s. per qr. Floating cargoes were down fully 1s., with little demand. The weather continuing very fine all this week, with improved prospects as to the general yield of wheat, all the country markets showed a downward movement, and some went beyond the London decline of 2s., as Salisbury, St. Ives, Sheffield, &c., where rates were down 3s. for old wheat, there not being enough new to make prices quotable or settled. Edinburgh gave way 2s. to 3s., and Glasgow 1s. per qr. Dublin was 6d. per barrel cheaper, with hardly anything passing.

The fourth Monday had a small supply of English wheat, but a good arrival of foreign, though not equal to the previous Monday. There was but a moderate show of fresh samples during the morning on the Kentish and Essex stands, more than half being new, prices of which settled down at from about 58s. to 61s. per qr. Old also was down 3s. to 4s., with scarcely any demand for it. To sell foreign there would have been a similar decline; but we did not hear of any house being anxious to press at such a large reduction.

The imports into London during the four weeks were 10,584 qrs. English wheat, 132,556 qrs. foreign, against 9,635 qrs. English, 118,022 qrs. foreign for the same period in 1867. The London averages commenced at 67s. 5d., and closed at 63s. 3d. per qr. The general averages commenced at 67s. 5d. and ended at 65s.

The imports into the kingdom for four weeks up to 18th July were 2,846,067 cwt. wheat, 213,922 cwt. flour, against 1,994,965 cwt. wheat, 209,704 cwt. flour in 1867. The exports from London during the month were 910 qrs. wheat, 210 cwt. flour.

The flour trade has been equally dull with wheat. The first fortnight prices stood much the same; but in the third week country sorts were down 1s. to 2s. per sack, and town prices were reduced 2s.; while on the fourth Monday there was a further reduction of about 2s. on Norfolks and other country sorts, and town millers found it necessary to make a further reduction of 4s. per sack, bringing the top price down to 54s., thus showing a difference in flour of only 10s. from the extreme price, while the reduction in wheat has been 20s. The prices of French are now lower than they are in Paris; but New York may yet import from last advices, with chance of a small profit. The imports into London for four weeks were—in country sorts 49,320 sacks, in foreign 7,811 sacks 5,640 barrels,

against 59,975 sacks English, 8,634 sacks foreign for the same period in 1867.

The imports of maize have been fair, viz., 24,952 qrs. for the month; but there having been more inquiry for this grain since its reduction in price, there has been a reaction of 1s. per qr. in favour of sellers. Egyptian was worth 34s. to 36s., American 37s. to 42s. There have been fair exports from New York lately; but at present we do not anticipate much reduction in prices.

Very little barley of home-growth has come to hand during the month, the stocks being apparently exhausted; but there have been fair foreign arrivals, principally grinding qualities, which range from 30s. to 32s. per qr., and the better qualities to 36s. Some new English has brought 45s.; but very little has yet come to market. Some fine has been sold in the country at 46s. per qr. The quality is mostly steely and somewhat thin; but there is some stout and of very beautiful colour, whatever the yield may be. We think fine malting sorts are likely again to rule high all through the season, and that even low descriptions will be relatively dear. The imports into London for four weeks were—in British sorts 1,032 qrs., in foreign 47,656 qrs., against 1,029 qrs. British, 12,555 qrs. foreign in 1867.

The malt trade through the month has been very steady, without quotable change of values.

There has been an enormous importation of foreign oats during the month, but they were too much wanted, from the deficiency of our own crop and the shortness of stocks, that it has very little affected prices. Fine qualities have been very scarce, the bulk of the arrivals being only of the middling and inferior sorts, which have brought 23s. to 27s.; but good were worth 28s. to 31s., and even more when procurable. We believe we shall again require large imports, and that we shall have to compete with France as a purchaser, as the crop of that country is expected to be as deficient as our own. The few new, however, yet exhibited have been fine and heavy, where grown on strong soils. The imports into London for four weeks were 921 qrs. English, no Scotch, only 420 qrs. Irish, but 350,162 qrs. foreign, against 1,934 qrs. English, 216 qrs. Scotch, 110 qrs. Irish, 208,736 qrs. foreign in 1867.

We have had but few English beans and only a moderate supply of foreign, but it has been enough to keep the London market fairly supplied, while the hot weather and high rates have lessened consumption. During the month prices have advanced about 1s., but they are now checked by the lower rates of maize and grinding barley. The imports into London for four weeks were 1,362 qrs. English, 7,500 qrs. foreign, against 966 qrs. English, 2,149 qrs. foreign in 1867.

For a long period the supply of English peas has been very scanty, but for the last fortnight they have rather increased by the appearance of new samples of very fine quality, though we hear the yield is reckoned to be very deficient. On the last week we had a fair arrival of foreign white. Prices through the month gained about 1s. to 2s. per qr.; but boilers were finally a slow sale at 46s. The imports into London for the month were

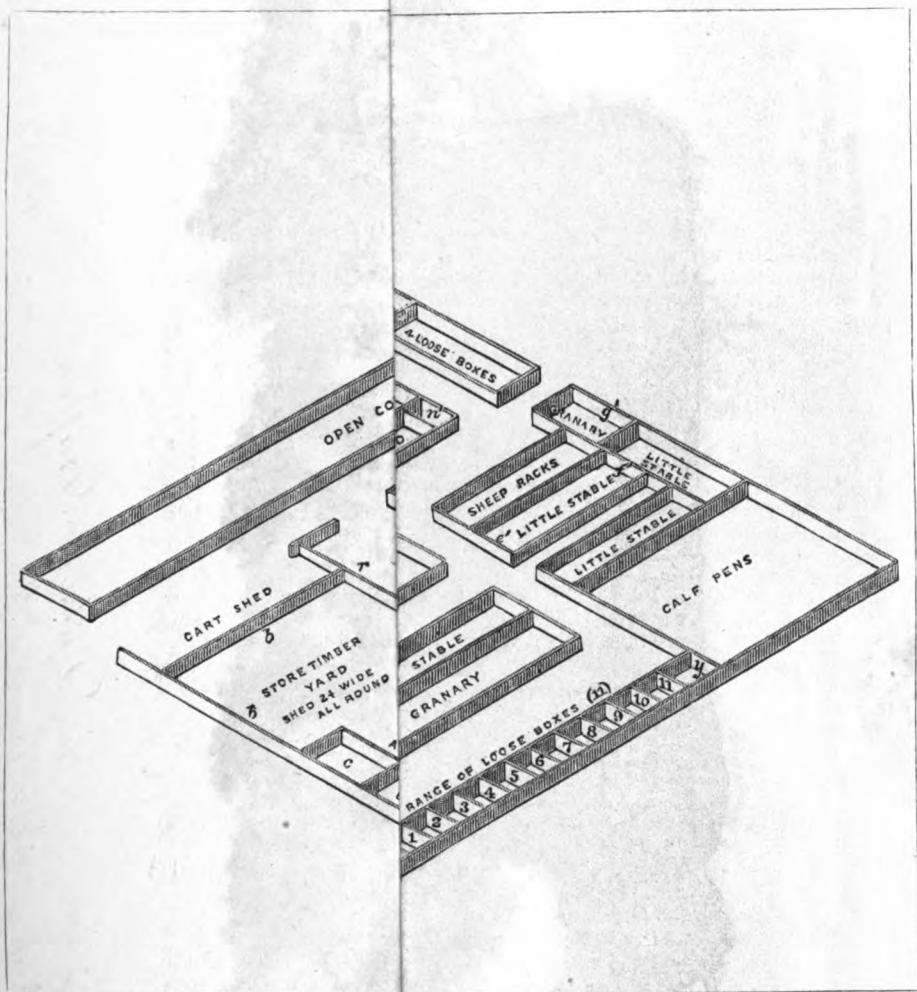

*The Duke of Grafton*  
*A large Horned Bull, property of the Earl of Grafton, bred at Grafton, London, published by the engraver, R. Smith, 1844.*

## PLATE V.

### THE DUKE OF GRAFTON; A PRIZE SHORTHORN BULL.

THE PROPERTY OF MR. JAMES CHRISTY, JUN., OF BOYNTON HALL, CHELMSFORD.

The Duke of Grafton, a red bull, calved April 15, 1864, and bred by Lord Penrhyn at Penrhyn Castle, Bangor, is by Duke of Geneva (19614), out of Duchess 1st by Master Rembrandt (16545), her dam Duchess Nanny by Jasper (11609). — Duchess Nancy by Second Duke of Oxford (9046). — Nettle by Second Duke of Northumberland (3646). — Nell Gwynne by Belvedere (1706). — Northallerton by Son of Second Hubback (2683). — a Cow of Mr. Bates of Kirklevington.

Duke of Geneva (19614), a red bull, calved February 16, 1860, and bred by Mr. J. O. Sheldon, Geneva, America, was imported into this country in 1862, and sold to Lord Penrhyn for 600 gs. He is by Second Grand Duke (12961), out of Duchess 71st by Duke of Glo'ster (11382), her dam Duchess 66th by Fourth Duke of York (10167). — Duchess 55th by Fourth Duke of Northumberland (3649), and so back through a whole line of Duchesses to Belvidere and Hubback.

Duchess 1st was bred by Mr. Barber, of Sproatley Rise, Hull, and sold at his sale in 1862 to Lord Penrhyn for 135 gs. She is out of a cow bred by Col. Towneley, the dam of which was purchased at Messrs. Bell's sale at Kirklevington, 1850, from whose stock Duchess 1st is descended. She won two first prizes as a heifer calf in the East Riding of Yorkshire, and her sire, Master Rembrandt, won nine prizes in Yorkshire and Lincolnshire, including a medal and cup.

The Duke of Grafton won the first prize at the Essex County Show at Baintree in 1867, and the first prize at the same Society's show at Chelmsford in 1868, in a class of 16 animals open to all England. He also won the first prize with Primula and her heifer calf Potentilla, for the best bull, cow, and offspring, against five other entries. Primula has also taken, on her own account, at the Essex meetings, first prizes as a calf, yearling, a two-year-old, and a cow.

We thus spoke of the Duke of Grafton on seeing him at Chelmsford in June:—"Mr. Christie kept the prize in the county with a big, long, broad four-year-old of nice quality, and with some capital points, being especially good in his back and hind quarters, and well let down to his hooks. Against all this, he is light in his neck, and has a rather tapering egg-

sucking head, but is, nevertheless, at all points, a grand useful bull. He could not take the first prize class of the county, because he took it in 1867; but the judges held to his line as far as they could. They made his daughter Potentilla their choice in the youngest class of heifers, and then took her with her father and mother as the best family party; while they got on the vein again with his daughter Patchouli 4th, a well grown, handsome yearling, of good colour and quality."

Mr. Christy's herd was commenced in 1849 by the purchase of two heifers at Mr. Barnard's sale at Gosfield Hall, and from one of these—Cowslip by Roan Robin (10721)—the main strength of the stock is derived. From this cow is descended the P family, members of which have been exhibited, and always with success, at the Essex County Show since its commencement in 1858. Cows or heifers have also been purchased from C. P. Grenfell, of Taplow Court, in 1857; from Mr. G. M. Tracy, of Edenbridge, in 1859; from Mr. J. S. Crawley, of Stockwood Park, in 1860; from Mr. W. T. Longbourne, of Blackmore, in 1858; from Mr. Jonas Webb, of Babraham, in 1863, and from Mr. J. H. Langston, of Sarsden, in 1864.

The farm adjoins Mr. J. W. Bramston's Skreens estate, and the bulls used on the Bramston herd of late years have also been used at Boynton. Amongst these have been Tortworth (10966), and Red Duke (16798), with much Bates blood, Comedian (15789) from Mr. Adkins' herd, while the Duke of Grafton has more recently been the lord of his own harem.

The herd now numbers 57 animals, viz., 25 cows, 13 heifers, 7 yearlings, 10 bull and heifer calves, and 2 bulls. The cattle are of good medium size, not coarse, with good ribs and loins. In colour red prevails, and they are generally uniform, more especially the P family. The stock is not kept high, nor pampered, but in good healthy condition for use.

The Boynton Hall farm, held from Lord Petre, consists of 700 acres arable under steam cultivation, and 100 acres of grass. Although good useful land it is not of the best quality, but it has been improved of late years, Mr. Christy being considered by his neighbours one of the best and most advancing agriculturists in the district.

## PLATE VI.

## THE FARM BUILDINGS AND KENNELS AT LUTON HOO.

In the year seventeen hundred and eighty-one two celebrated men joined in drinking the health of his then Most Gracious Majesty George the Third at the village inn of Luton, in Bedfordshire. And on that occasion one of them dictated to the other a letter—written and sent years before—to “My Lord Chesterfield,” which many a time since has been read with mingled feelings of melancholy and pride—melancholy that so great a man who had originally penned it had been subject to the neglect, if not the contumely, of the “pride of birth and of place;” pride that that man could so pathetically, yet nobly, vindicate the dignity and the worth at once of his calling as a “man of letters” and of his manhood. One of these men was the celebrated Samuel Johnson; the other, James Boswell—no less celebrated certainly, but in a much smaller, and quite in another way. We do not know whether this inn still exists in Luton, or if it does, whether tradition has marked the room, if not the very place in the room where those two men sat—one of whom has written his name in the page of our country’s history; the other who has written—well, we shall content ourselves with saying one of the most amusing books which was ever penned—but if the inn does exist, and the room is marked in memory of man, the next time we visit the beautiful neighbourhood of Luton we shall make a pilgrimage to that inn, and reverentially quaff a draught of its best ale in memory of one who influenced his times in a remarkable manner for good—a memory which all good men bear lovingly in mind.

On the day which preceded the evening we have named above, Johnson and Boswell visited the magnificent seat of the Marquis of Bute at Luton Hoo, now written Hoo, and we can fancy the remarks which Johnson would make in his grand bow-wow way, with his “Sir” this and his “Sir” that, and the way in which he would be attended and, shall we say, toadied by the obsequious Boszy. Johnson was so pleased with the Hoo, that he said of it, “This is one of the places I do not regret having come to see. It is a very stately place, indeed; in the house magnificence is not sacrificed to convenience, nor convenience to magnificence. The library is very splendid, the dignity of the room is very great, and the quantity \* of pictures beyond expectation—beyond hope.” This fine place was entirely burnt sixty-two years after John-

son visited and thus expressed his high opinion of it. Whether the house which was built to replace the magnificent mansion which thus called forth the praises of Johnson is the one at present on the estate, we know not; but, whether or no, it belongs not now to the “lordly house of Bute”—it has passed from the aristocracy of birth to that of wealth—and we commit no flattery when we say—of worth. The estate on which the present mansion stands is now in the possession of one of the leading men of “Lordly Liverpool”—that town of merchant princes—Mr. James Gerard Leigh.

We hear very much just now of the wonders that would be worked by the introduction, or rather the revival, of small farms; but if any one who is enamoured of this system—one which is, as far as experience goes, by no means adapted for this country—will only take the trouble to contrast a specimen of it with the large farms of men of means, who, by wealth judiciously distributed, and ably aided by sound practical farming knowledge, carry out extended improvements, we venture to say that he will begin to think that his notions as to what can be done by small farms in the way of furthering, and furthering quickly, the progress of agriculture, are necessary to be thought over again, and are very likely to be set aside as the result of this fresh thinking. And the estate of Mr. Leigh is precisely one to which we would send the advocates of small farms to gain knowledge of how wonderfully the progress of farming, in its highest and most scientific developments, has been aided by the judicious expenditure of money and knowledge on large and extensive farms.

Before describing what has been done in improving the land, or farm proper, we shall take up the buildings by which the work of the farm is carried on. These, as our chief sketch will show, constitute in fact a “monster farmery, or homestead.” We are no believers in what are called “model” farmeries, inasmuch as the peculiarities of every well-designed farmery or homestead are regulated and brought into existence by the peculiarities of the farm for which it is designed, and those of soil, climate, and locality. Hence no farm can be said to have buildings which are “model” farm buildings, in the sense in which the term “model” is generally, we may almost say universally, used, that is applicable to be taken as a model to be followed in all places; but a building may be a model one, as applicable to a farm placed under the like circumstances in which it is placed, and may, moreover, if it is not a model one as a whole, possess many features which are worthy of being followed as models for practical copying. In this sense, and which we take it is the correct sense of the term, the farm buildings at Luton Hoo estate are model ones. Certainly, they are most extensive, “monster,” as we have already termed them.

\* We cannot here resist the temptation there is to express our surprise that the great lexicographer, the eminent philologist, should here have used the word “quantity” as applied to precious things as pictures. We apply, or ought to apply, this term only to things of abundant bulk, as wheat, sand, &c., &c. We apply, or ought to apply, to precious things as men or pictures—as in the present instance—the term “number.” So absurdly is the term “quantity” employed now-a-days, that we hear of a “quantity of men.” When we so hear, we are inclined to ask “How many bushels or gallons of them?”

and comprise many features worthy of special notice. This notice we propose now to give.

As the buildings in their complete arrangement, and the component parts occupying their relative positions, occupy so large a space of ground—some six or seven acres, including every detail—to represent them all on one plan, so that all the parts would be on such a scale as to make them intelligible, would involve either a larger drawing than our page could afford space for, or if brought down in scale to go therein easily, would be so minute as to reduce the practical value of the whole, which we propose if possible to give to our drawings; we have therefore adopted the other alternative, of giving, in the first place, an isometrical *block plan*, in which the relative positions are easily seen; and in the second a series of detached plans, drawn to a large scale, from which the fittings-up of the various apartments can be easily seen. We believe this plan of illustrating this fine and extensive series of farm-buildings the best adapted to place its peculiarities before our readers. We therefore give the block plan, shewing all the apartments in their positions relative to one another, and give here the general description of the same, reserving the detailed description of the various apartments till we present our detached plan. Beginning at the upper end of the block plan in the Plate, we find first the open corn-shed—for storing the corn in sheaves as brought direct from the fields, in place of having it open stacked—the length of which is 450 feet, and the width 36. At the end of this are two “loose boxes,” numbered 16 and 17 respectively. The whole of the central part of the farmery, at the upper part, is occupied with places for the stock, the upper line next the corn-shed being occupied by the top bullock-shed, on the lower side of which are the manure-yards. The open yards (Nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10) are each provided with good store-rooms, as 2' 2', m' m', n' n'. At one end of the piggeries there is a boiling-room for preparing the food at j1, j2 being a privy. The large root-store has at one end an oilcake room (i), and the steam-engine room (S3); at the other end, the slaughter-house (Z). The milk-cow house ranges with the bottom bullock-shed. Separated by a wide cart-road, paved with granite, from the milk-cow house and bottom bullock-shed, is the range of buildings which contains the boiler-house (B), the steam-engine and mill-room (S1), the chaff-house, the coal-house, the hen-house (d'), the plough-iron stores (b'), and the saddler's shop (c). Below this range are the stables for the work-horses, with granary and coach-house (Z), and shed (a1). Facing these, and lower down, are a range of loose boxes (Nos. 1 to 11), with apartments at one end, as follows: t—bedroom belonging to the house and offices, of which a detached plan will hereafter be given; u—a tool-house; v—a mess-house for the workmen; w—coach-house; x—a nag-stable. The other end of the range of loose boxes (Nos. 1 to 11) is the boiling-room for calves' food (y) the calf-pens being adjoining, and divided as follows: a a a being the pens, with feeding troughs b b b, passages c c, and hay-racks d d; the dimensions of the central

range of pens being 22 feet square, of the upper range being 22 feet by 21 feet, of the lower range being 22

(Fig. 1.)

feet by 18 feet, of the end range 17 feet by 16 feet, the width of passages c c being 6 feet. Next to the calf pens are the little stables for the cart-horses, with a harness room at one end and a loose-box at the other, not shown in the plan, but in the position e1 and f1 respectively. Above the upper range of stables are the sheep pens; these being bounded on the side with the shepherds' granary. In a line with this, and further up, are four loose-boxes, Nos. 12 to 15 inclusive; above which is a shed; then a steam-engine room, for working the bone crusher; and above this, the implement shed.

Taking now the other side, or left of the block-plan in the Plate, we find first, as next to the cattle yards, the range of barns, as the oats, the wheat (with steam engine S4), and barley barn; p1 and q1 being seed rooms. To the left of these, divided by a granite-paved road, are the various workshops, these being placed round the central timber yard. The upper part of the timber yard is surrounded with a shed (b b b) 20 feet wide, c is the bricklayers', d the iron store, e a store, f smiths' shop, with shoeing house g, h the wheelers' shop, i mess-house for workmen, j position of stairs leading to the painters' shop above, k fire-engine house, l carpenters' and painters' stores, m carpenters' shop, with store room p, o the saw room, S5 the steam engine for working the circular saw under shed b, r r the cart shed, with store n for grains at one end. We have thus described the arrangement and position of the various parts which make up this vast building, and are now prepared to enter into a somewhat detailed description and illustration of some of its most striking characteristics.

And the first of these which claims our attention is the *distribution of power and of machines for performing the various operations of the farm*. Unlike the system which may be said to be universally adopted, we find here no concentration of power, and of the machines which that power is designed to work; on the contrary, we find a division of the power, and of the attendant

machines, these being spread over various parts of the building, as indicated by the position of the steam engines, not fewer than five in number, as indicated in the block plan in the Plate, by the letters S1, S2, S3, S4, S5. Some points of essential importance concerned in the economy of performing the labour of a farm, especially of a large one, are involved in the system here illustrated, which to the reader practically interested in the working of a farm will be interesting if explained somewhat in detail. But before doing so it will be well to give here our detailed plans to a larger scale, about 23 feet to the inch-and-a-half, showing the arrangement of the power, and the

machines in the various parts of the building. In fig. 2, we illustrate the arrangements in the range of buildings next the work-horse stables, in which *a a* is the steam boiler house, containing two forty-horse power steam boilers, on Howard's recently introduced principle. We shall presently explain why there is such an exceptionally—an apparently exceptionally large amount of boiler power given here; meanwhile we proceed to describe the other arrangements illustrated in fig. 2. The boiler house *a a a* is separated by a covered way *b b* from the mill house *c c*. This has at one end the apartment *d*, which contains a twelve-horse steam engine *e*; this works by means of the shafting *f f* and *g g* the various machines as follows:—*h* the grindstone, *i* the chaff-cutter, both of these being placed in the chaff-room *j j*, the shafting *g g* being suspended by "hangers" from the ceiling, and receiving motion from the shaft *f f* by the pulley *f k*, and belt *l*. In the room *c c*, *m m* are corn mills, and *n* an oat-crushing mill. The machines here do the work which is required chiefly for the horses, the stables and loose-boxes for which are all in the immediate vicinity, and can therefore be supplied with all despatch.

(fig. 2.)

Coming in like manner to the preparation of the food for the cattle, we find our way to the "root store," where the open yards Nos. 8 and 9 (see block-plan in Plate), in which we find another steam-engine (marked S3 in fig. 1) together with another set of machinery, all of which are illustrated in fig. 3, in which *a a* is the oilcake store, *b* the steam-engine room, containing 4-horse power steam engine, driving the various machines by means of the shafting *d d*: these machines are *e e* the oilcake breaker, and *f* the root cutter, the roots being stored up in the shed *g g* (see block-plan in Plate). The oilcake and the roots there broken and sliced are ready to be delivered to the stock in the various cattle yards adjacent.

Returning to the right-hand side of the building we come to the implement shed (see block-plan in Plate), and there find another steam-engine placed to prepare the manure of the farm, as illustrated in fig. 4; the steam-engine *a* in room *b* being of 10-horse power, working the bone-crusher *c*. On the opposite side of the building, that devoted to the barns, we find the fourth steam engine, as indicated by the detached plan in fig. 5, where *a* is a steam engine of 10-horse power, driving the thrashing machine *b*, and a powerful hay cutter in the room above, access to which is had by the stairs *c*. We now come to the fifth

steam engine employed in this monster building, being that employed in the workshop department, and illustrated in fig. 6, in which *a* is the carpenter's store, and *b* saw room (see *o* and *p* block-plan in Plate), *c* steam engine of 16-horse power, driving by the shafting *d* and belting *d'* the saw mill *e*.

In finding, as the result of our detailed examination of the plan of this large farmery that both the power and the machines employed are not concentrated in one place, but distributed in several places, the question naturally opens itself up, why should this be, and how should a plan so opposed to that ordinarily, we may say universally employed, be adopted in preference, and what are likely to be the advantages arising from its adoption? It is worth while to devote short space and brief time to some of the points involved in the answer to these questions.

Some twenty years ago, or thereabouts, when called upon to examine the disastrous effects arising from a "break-down" of the gigantic steam-engine, which alone drove the machinery of a still more gigantic factory in the manufacturing districts, we were very forcibly led to speculate upon the whole circumstances of the case, and

to ask ourselves, why should the whole work of a mill be stopped, and all the hands employed in it be thrown out of employment by the sudden stoppage of power which drove the machinery? We did not, indeed could not, possibly ignore the fact that steam engines, like men, would sometimes break down—a most expressive phrase

(Fig. 8.)

by the way—either through over-work, organic weakness, or functional derangement. But then it appeared to us that if by some means or another we could cease concen-

trating the power of the factory into one gigantic engine, and break up or subdivide that power into a number of small engines, we would at least lessen the ratio of loss

(Fig. 4.)

(Fig. 5.)

arising by a break-down. "Divide and conquer" was in fact the ruling principle we thought of, which could be in the present instance illustrated by other metaphors—"it is not safe to put all one's eggs into one basket," "all one's cargo into one boat." We therefore advocated the prin-

ciple of so laying out the power necessary to drive the aggregate number of machines, that one steam engine would drive one set, a second steam engine drive another set, and so on; and we maintained then, as we maintain now, that as the chances were that at no time would all these steam

engines be broken down—that if one did break down its neighbour would be at work; that then *all* the machines would not be stopped. We even went the length of advocating that for each heavy or large machine we would appropriate its own special engine. This extreme extension, as we may call it, of the principle was considered as altogether unlikely to be ever carried out; yet although not so carried out in factories, it is now being carried out in machine shops for the working of machines.

(Fig. 6.)

tical knowledge was able to realize the plan which we now see embodied in the block-plan in the Plate, and in the detached plans in fig. 1 to 6 inclusive. The essential feature in this plan is the establishment of a central source of steam supply in the building marked B in the Plate and *a* fig. 2. This being given in the form of two forty-horse boilers, hereafter to be described. From these boilers the steam is led by pipes to all the steam engines, the positions of which are shown in the block-plan in Plate, at S1, S2, S3, S4, and S5, and in detail in figs. 2 to 6 inclusive; the range of pipes is shown by the dotted line in the Plate proceeding up from boiler-house B, between the ranges of cattle-yards, and then branching off right and left to the implement shed on one side, and to the work-shop on the other. This steam-pipe is indicated in the various detail plans in figs. 2 to 6 by the letters O O. The pipes are laid in trenches in the ground, and all loss by radiation is prevented by contrivances which will hereafter be described.

At first sight the question may be raised as thus: If it is a good thing to take the steam-engine to the place where the work is to be done, not only because you get it thus directly to its work, but because you save the chances of loss arising from the break-down of one large central engine, does the same principle not apply to the steam boilers? If it is wrong to have a central steam engine, is it not wrong to have a central steam boiler? If this breaks down, or, what is just as likely, or perhaps more likely, blows up, what becomes of your steam engines? There is great force, at first sight, in the objection which these questions involve; but certain considerations come into play in the case of the steam boiler which do not operate or exist in that of the steam engine. The main consideration is that in a place like a farm-stead, where so much combustible matter is lying, and, in windy weather, flying about, it is not safe to multiply the chances of fire, which would be done by multiplying the number of steam-boiler furnaces; for let it be noted here that while by having only one central boiler you may place that in the safest position, and be able to make special provisions by which the danger from the furnaces is isolated, you moreover get rid of another source of danger by having a large and tall chimney, from which sparks, as a rule, never issue; but, on the contrary, if you

The principle in other words may be said to be the taking of the steam engine to the work, wherever that may be, and is most conveniently performed—thus, of course, multiplying the number of the engines as you multiply the sources of the work. You not only thus obtain a concentration of direct power precisely where it is wanted, but you get rid of the necessity of employing heavy gearing, and long ranges of shafts, and numbers of driving pulleys and belts; all of which are costly, and all of which absorb a large percentage of the power in merely driving them; whereas you want to do the work as directly and economically as possible. All this heavy gearing and shafting being absolutely essential where you employ one central source of power, and lead this off to various places at varying distances where it is required to do certain work. In saying that we advocated this principle of dividing steam power, and placing it exactly where it is required to do the work, many years ago, we by no means wish it to be inferred that the principle was thought of by no one else or advocated: the reverse of this; although at the time we advocated it few, very few, had done so, and many more were opposed to it than in favour of it; as, indeed, may be said to be the case even now, except in the cases of the most advanced engineers of the day. But our opinion of it having been so formed, and so long ago, we were therefore quite prepared to endorse the application of the principle to large farm buildings, as propounded to us by Mr. James Ross, the highly-intelligent and active agent of the Luton Park estate, to whose abilities nearly all of the improvements both in the estate and in the buildings on it are due. Yet, strange to say, or rather from what we have above said by no means strange, Mr. Ross, in talking over his plan of distributing the steam power over the building where wanted, by no means met with the encouragement which the “common-sense principle,” as he very graphically and truly calls it, seemed to his mind so well calculated to secure. At last, in Mr. James Howard, of the firm of Messrs. James and Frederick Howard, of Bedford, Mr. Ross met with one who not only at once heartily and fully entered into his views, but by the application of his practical

place here and there a number of steam-boiler furnaces where the steam engines are placed, you put these furnaces in the position which is precisely the most dangerous, for you place them near dangerous materials; and, moreover, where the power of the boiler is small, and not judiciously, as is sometimes the case, engineered (if we may use the expression), the chances of sparks arising from the chimneys are greater than in the case of larger fires. Further, it is more economical of fuel to raise steam in, say, two large boilers, than in five smaller ones placed under different circumstances. Moreover, by having thus centrally raised steam, you can turn it to any one steam engine at a moment's notice, and work it, if it should only be required, for half-an-hour; whereas, to raise steam in a separate boiler for only this short duration of working would be evidently a loss. At the same time we by no means are

disinclined to admit that where the circumstances of the farmers will permit of it, it would be better to distribute steam-boiler as well as steam-engine power over the farmery where the power is required, thus both in steam and engine lessening the chances of losses by either the one or the other breaking-down or blowing-up, as the case may be, in the one case, to put the point in rather involved fashion. The arrangement, however, as indicated in the plan, has been, in the case of Luton Hoo Farm, well thought over, and only carried out after mature consideration. As carried out, it is a perfect success. We saw the system in full operation, under circumstances which could not possibly be more disadvantageous to its successful working, and yet it worked in every way successfully: it is still so working. What have been the means by which this success has been attained we shall describe in our next.

(To be continued.)

## WARM SUMMERS.

BY CUTHBERT W. JOHNSON, F.R.S.

The effect of varying temperature upon our cultivated crops is a theme of considerable interest to my readers. An unusually warm summer, like that of 1868, naturally suggests to us more than one branch of the inquiry. To avoid, however, taking into consideration matters which would lead us far beyond our assigned limits, let us on this occasion confine our attention to the effects of a high summer temperature upon the wheat plant.

We need hardly remind ourselves that the best wheat is grown in climates where the mean temperature is high, and the rainfall very small. At Madrid the annual rainfall is only about 10 inches: in Egypt there is hardly a shower.

Then, with regard to the average temperature of England, Madrid, and Cairo, during May, June, July, and August, it is as follows:

	May.	June.	July.	August.
England...	56	59	63	62
Madrid ...	63.10	71	78	78
Cairo .....	78.26	83	85	85

Some years since the farmer's attention was drawn to this inquiry by Mr. Whitley, in a very valuable prize essay, and to this he has recently added another report (*Jour. Roy. Ag. Soc.*, vol. xi. p. 1; vol. iv., N. S., p. 88). Now as he well remarks in one portion of his Essay: "As a general rule, we find that where the mean temperature of a district is high, that there the corn produced is excellent. The mean annual temperature of Edinburgh is 47.7; Keswick, 46; London, 51.9; Philadelphia, 52.5; Cairo, 78. The effect, then, of increase of mean heat is to improve the value of the corn; but there are many causes which modify and vary this general rule. The great heat of a Polish or Russian summer, for instance, more than compensates for its shortness. The length of the days of a northern summer, by giving the extra stimulus of light, also materially aids the rapid maturity of the crop. Amongst retarding influences must be classed the elevation of the land. From the observations of Schubler, in Saxony, he drew the conclusion that every 98.26 feet caused a delay in the harvest of wheat, barley, and oats of 2.2 days. In our climate, all other things being the same, we think that nearly a similar rule of retardation is observable; but here, again, many circumstances cause a deviation from the rule—such as the nature of the soil, and more especially the subsoil, and the more or less rapid rate of elevation. The harvests on gravelly or silicious soils are much earlier, and those of clay soils much later, than our calculations

with regard to the climate or elevation would justify. The harvests, for instance, on the gritstone or moorlands of Yorkshire, at an elevation of 500 feet above the level of the sea, are always later than on its Chalk Wolds at 800 feet. We may, perhaps, take it as a general fact, that all land in England, at an elevation of 1,000 feet above the sea, can only be profitably employed in pastures. The line of extreme cultivation rises gradually as we approach the equator. In some of the Steppes of the Himalayas barley is successfully cultivated at more than 14,000 feet above the level of the sea; wheat up to 12,022 feet—the height of our highest mountains is only about one-third of this—Helvellyn is 8,055 feet; Ben Macdui, 4,148; Macgillivuddy in Ireland, 3,410. The result of Mr. Kirwan's observations was, that in moderate rates of elevation above the level of the sea, such as at the rate of 6 feet per mile, for every 200 feet of elevation the mean annual temperature would be reduced  $\frac{1}{4}$  of a degree; that if the rate of elevation was 7 feet per mile,  $\frac{1}{3}$  of a degree must be allowed; if 13 feet, then  $\frac{1}{2}$  of a degree; and if at the rate of 15 feet or upwards, then  $\frac{2}{3}$  of a degree must be allowed. In rising above the level of the sea, the mean temperature gradually decreases, until at length we arrive at the line of perpetual snow."

Temperature, we all know, materially influences the system of cultivation adopted even in different districts of our islands. It may be useful, then, if we examine the records kept in 1847 and 1848 at three stations in corn-growing districts, viz., London, Thwaite in Suffolk, and Thetford in Norfolk, and contrast them with the register kept at Falmouth, Exeter, Manchester, Whitehaven, and Durham (all pasturage localities), and note the mean monthly temperature of these places during the corn-maturing months of June, July, and August. The following are the results:

### CORN DISTRICTS.—1847.

	June.	July.	August.
London ... ..	58.5	65.8	63.7
Thwaite ... ..	59.1	65.9	64.3
Thetford ... ..	62.5	72.0	69.5
Mean of three stations ... ..	60.0	63.6	65.8
1848.			
London ... ..	59.76	62.98	59.71
Thwaite ... ..	60.37	63.97	62.39
Thetford ... ..	64.5	70.00	63.00
Mean of three stations ... ..	61.54	65.4	61.7

## PASTURAGE DISTRICTS.—1847.

	June.	July.	August
Falmouth ... ..	56.9	61.9	58.1
Exeter ... ..	58.9	63.9	62.4
Manchester ... ..	58.4	64.9	60.3
Whitehaven ... ..	57.7	63.2	58.8
Durham ... ..	55.7	61.5	56.5

Mean of five stations ... ..	57.5	63.1	59.2
------------------------------	------	------	------

1848.

Falmouth ... ..	57.64	60.35	57.93
Exeter ... ..	58.42	60.76	58.76
Manchester ... ..	59.48	61.44	59.73
Whitehaven ... ..	57.56	59.87	59.87
Durham ... ..	58.96	59.14	57.26

Mean of five stations ... ..	58.4	60.3	57.3
------------------------------	------	------	------

The mean temperature at Greenwich, on an average of 35 years, from 1815 to 1849, was (*Belleisle on Thermometer*, p. 50):

January ... 36.47	May ..... 53.74	September. 57.30
February.. 38.78	June ..... 59.74	October ... 50.41
March .... 42.04	July ..... 62.47	November. 43.62
April ..... 46.78	August ... 61.90	December . 39.41

The mean temperature of the seasons, in periods of five years during that portion of time, was as follows: Spring, including March, April, and May; Summer, June, July, and August; Autumn, September, October, and November; and Winter, December, January, and February (*ibid*, p. 52):

	Spring.	Summer.	Autumn.	Winter.
1815 to 1819.....	47.93	61.99	50.49	38.36
1821 „ 1824.....	47.92	61.01	51.40	37.96
1825 „ 1829.....	47.86	62.16	50.41	38.91
1830 „ 1834.....	48.25	60.93	50.52	38.28
1835 „ 1839.....	45.23	61.35	49.41	37.64
1840 „ 1844.....	48.58	61.00	49.87	37.95
1845 „ 1849.....	47.39	61.56	50.73	38.67

35 years' mean ...	47.55	61.43	50.42	38.22
--------------------	-------	-------	-------	-------

Mr. Whitley has carefully and laboriously examined the effect of the temperature of the seas which surround us upon our climate (*ibid.*, vol. iv., N.S., p. 55. Similar observations upon this great influence of the sea early attracted the attention of mankind. Camden quotes several ancient authors to this effect. Thus Minutius Felix observes (in the third century): "Though Britain enjoys not so much the aspect and influence of the sun, yet, instead thereof, it is refreshed and comforted by the warmth of the sea which surrounds it." And Cicero remarked: "The seas, tossed to and fro with the winds, grow so warm, that hence it may be reasonably inferred that there is a certain heat that lies concealed in that vast fluid body."

Mr. Whitley has given the following table of the relative amount of heat at the places mentioned during the winter months:—

PLACES.	Dec.	Jan.	Feb.	Mean.
	Deg.	Deg.	Deg.	Deg.
Scilly Isles .....	48.0	46.3	45.8	46.7
Cork .....	42.8	43.9	44.5	43.7
Sandwick (Orkney) .....	41.0	39.6	38.4	39.7
Penzance .....	45.2	42.6	44.9	44.2
Exeter .....	42.3	41.0	41.1	41.5
Greenwich .....	39.8	36.9	38.7	38.5
Edinburgh .....	39.7	37.4	38.2	38.4
Montpellier .....	45.7	42.1	44.8	44.2

We find from this table, as he observes, that during the three winter months Penzance has a temperature precisely the same as that of Montpellier; Cork falls short of it by only half a degree; and the heat of the Scilly Isles exceeds this noted winter resort by  $2\frac{1}{2}$  degrees.

At this season Edinburgh has the same amount of heat as Greenwich, although 350 miles further north; and yet 200 miles further, at Orkney, the winter temperature

exceeds that of Greenwich by one degree. But figures do not represent so vividly the geographical distribution of heat as lines of equal temperature, which show at a glance that our winter-warmth comes from the sea on the west. The lines cluster on our western coasts, and truly represent the waves of heat which in winter sweep in from the Atlantic, each wave being warmer than that which preceded it. These lines of equal temperature (isothermals) are given in an excellent meteorological work by Mr. A. Buchan, the Secretary of the Scottish Meteorological Society. He thus describes the effect of the Gulf Stream on our winter temperature: "The Gulf Stream leaves its impress unmistakably on the temperature of each of the months, as shown by the position of the monthly isothermals. In winter the deviation from their normal or east and west direction is greatest. Indeed, as regards Great Britain, the lines are then at right angles to this normal direction, and lie north and south. In Ireland they seem to envelope the island with their folds, which increase in warmth from the centre of the island outward to the ocean. This points out clearly that the great source of heat from which the climate of Great Britain derives its warmth is in the west; in other words, it is regulated by the ocean."

This winter warmth is first suffused along the western coast-line, and then sweeps up the valleys which open on the south-west to the sea. A glance at a geological map will show that all the older rock-formations have in these islands a general strike from the north-east to the south-west, and thus govern the direction of many open valleys and mountain chains. This is particularly the case in the south-west of Ireland, where the valleys and bays open funnel-like to the sea; and on the west of Scotland the firths and lochs have a similar arrangement. In England the bell-mouthed Severn opens up a passage for the warm wind to the middle of the country.

The flat surface of the middle of Ireland enables the westerly wind to have a clear sweep over most of the island; it afterwards sheds its heat on the plain of Cheshire, and deluges the Cumberland mountains with rain.

The hills which constitute the backbone of England form a dividing wall of climate, which may be traced from the Cotswolds northward along the crests of the Pennine range to the Cheviot hills. On the west of this line we have the warmth and humidity of the ocean, on the east the dry air and greater summer heat of the Continent. It is a wall which, so far as climate is concerned, divides the arable field from the grazing lands of England: on the one side there is a preponderance of corn-growing power, on the other of meat-producing capabilities. The texture of the soil and the demand at the market may modify this conclusion; but other things being equal, submission to the teaching of climate will in the long run be found the safest and most profitable course for the farmer to pursue.

After the end of April and during the summer months the British Isles receive no warmth from the surrounding seas; but the wide ocean on the west then produces a contrary effect. As the great wave of summer temperature sweeps northward over Europe, it is retarded by the cooler air from the sea on the western coasts, where the isothermals are bent southward along the coast-line from Denmark to Belgium.

The amount of heat which in July rests on the south of England is on the Continent extended further north than St. Petersburg; and in this month the summer heat is as great at Tornea and Archangel as at Edinburgh.

The comparatively low temperature of the water of the German Ocean in summer tends also further to reduce the influence which the high summer temperature of Central Europe would otherwise exert on the eastern plains of England; but any defect of our climate due to

this cause is more than compensated for by the equality of temperature and steady downfall of rain which we enjoy, and which give a capability of productive power to the soil of England far greater than the dry summer heat of the Continent could bestow.

The temperature of the surface of the Atlantic Ocean during every month and at every 10 deg. of longitude from the south coast of Ireland, crossing in our way the Gulf Stream, to the Banks of Newfoundland, has been given by Mr. Whitley in the following table:—

MONTHS.	On the Banks.	Degrees of West Longitude.				
		40.	30.	20.	10.	
	Deg.	Deg.	Deg.	Deg.	Deg.	
January .....	30	57	54	54	51	
February .....	31	54	52	52	50	
March .....	32	54	55	54	51	
April .....	34	57	55	54	52	
May .....	34	55	55	55	53	
June .....	40	60	58	58	57	
July .....	45	60	58	60	59	
August .....	50	61	60	60	59	
September .....	52	59	60	60	58	
October .....	47	59	56	57	55	
November .....	44	58	58	57	53	
December .....	32	55	54	54	52	
Mean of Year .....	39.2	57.2	56.2	56.2	54.2	

This table shows the extreme coldness of the water on the banks of Newfoundland for half the year, from December to May inclusive, when it is but little above the freezing point (32 deg.) The Arctic current, owing to its greater velocity at this season, and the icebergs with which it is then loaded, impinges with great force on the upper limit of the Gulf Stream, and presses it down full 200 miles to the southward; but this powerful current cannot thus be subdued; it first bends eastward, and then its northern edge curves up in a mighty eddy, like river-water below the piers of a bridge, along the eastern edge of the cold current, and folds it in its warm embrace. This remarkable eddy stands like a wall of fire on the eastern side of the cold current through which the icebergs cannot pass to chill our summers, or depress the genial warmth of our winter months. It has in January a temperature of 57 deg., which is higher than that of the air in the month of May on the south coast of England.

From this part of the ocean eastward, for at least a thousand miles in extent, the temperature of the surface water in January is about 54 deg., it reaches its minimum of 52½ deg. in February, and its maximum of 59½ deg. in September, having a yearly range of only 7 deg. Over this thousand miles from west to east the heat distributed through the water is in the various months remarkably uniform.

In passing through a brilliant warm summer like that of 1868, we are naturally inclined to compare it with other years. Now, we find that more than forty years have elapsed since, in 1826, we had a summer resembling in its dryness, and mean temperature, that of the present year. If we compare the rainfall of these summers we find that in the neighbourhood of London the amount recorded was as follows:—

	1826.	1868.
January .....	0.3 inches	3.69 inches.
February .....	1.7	1.06
March .....	1.7	0.81
April .....	1.0	1.72
May .....	2.5	0.78
June .....	1.0	0.26
July .....	2.4	1.16

10.6 " 9.48 "

Then as to the temperature these years, Mr. G. J. Symons has furnished us with the following record of the mean, maximum, and minimum temperature of each month in 1826 and 1868:—

	1826.		1868.	
	Max.	Min.	Max.	Min.
April .....	61	40	59	41
May .....	64	41	70	48
June .....	78	61	76	52

In the month of July the comparative temperatures during the first twenty-four days were as follows:—

Date.	July, 1826.		July, 1868.	
	Max.	Min.	Max.	Min.
1 .....	81	56	75	53
2 .....	88	52	77	55
3 .....	89	52	86	57
4 .....	86	60	72	56
5 .....	87	58	72	48
6 .....	87	66	72	52
7 .....	85	62	79	52
8 .....	83	64	84	54
9 .....	83	54	86	56
10 .....	80	56	82	54
11 .....	78	62	85	54
12 .....	78	64	83	56
13 .....	75	55	86	55
14 .....	78	60	88	54
15 .....	75	54	88	58
16 .....	73	40	91	61
17 .....	79	51	84	64
18 .....	78	58	86	62
19 .....	74	54	82	62
20 .....	72	59	90	55
21 .....	73	49	93	63
22 .....	74	50	93	64
23 .....	76	54	78	66
24 .....	70	55	77	49

Mr. Symons has added in another table the subjoined abstract of high temperatures at Camden-town, near London, since the year 1857, during the months of May, June, July, August, and September.

YEAR.	MAY.				JUNE.				JULY.				AUGUST.				SEPTEMBER.			
	Max. in shade.	Days reaching			Max. in shade.	Days reaching			Max. in shade.	Days reaching			Max. in shade.	Days reaching			Max. in shade.	Days reaching		
		70°	80°	90°		70°	80°	90°		70°	80°	90°		70°	80°	90°		70°	80°	0 °
1858	80.6	3	1	...	92.6	29	15	1	87.4	24	2	...	84.5	24	5	...	85.0	13	2	—

Like that of the present year, the harvest of 1826 was very productive: there was therefore little need of a foreign supply of corn. In 1826, only 814,851 quarters of foreign wheat and flour were entered for home consumption, and only 405,255 quarters in 1827; the import duty per quarter in 1826 being 11s. 3 $\frac{1}{2}$ d., and 21s. 4 $\frac{1}{2}$ d. in 1827. In the experimental plots of Mr. Lawes, at Rothamsted, where wheat has been grown continuously for a quarter of a century, the produce of seed in each year has been found to pretty closely represent the average produce of the Kingdom. Now the average produce per acre on these plots has been as follows—

Average of sixteen years..... 36 $\frac{1}{2}$  Bushels.

Produce in 1868 ..... 44 $\frac{1}{2}$  „

or more than 20 per cent. above the average.

The amount of wheat and flour imported in any year pretty clearly indicates the amount grown in our islands during the preceding summer. Mr. Caird has constructed the following table, which shows very clearly how, during five years, the supply of foreign wheat has nearly uniformly supplied the amount of the deficient preceding harvest:—

Crop.	Rate of produce of bushels per acre.	Total home produce.	Estimated requirements.	Foreign supply received during succeeding year.	Average price of that year.	Total supply.
		Qrs.	Qrs.	Qrs.	s. d.	Qrs.
1862	29 $\frac{1}{2}$	13,700,000	7,100,000	7,305,000	1863 44 9	30,805,000
1863	35 $\frac{1}{2}$	16,300,000	4,500,000	6,727,000	1864 40 2	33,027,000
1864	32 $\frac{1}{2}$	15,000,000	5,900,000	6,028,000	1865 41 10	21,028,000
1865	29	13,400,000	7,400,000	6,850,000	1866 49 11	30,250,000
1866	25 $\frac{1}{2}$	11,700,000	9,100,000	7,283,000	1867 64 4	18,983,000
			33,900,000	34,094,000		30,800,000 average of five years.

It is evident, then, as Mr. Simpson remarks (*Jour. Roy. Ag. Soc.*, vol. ii. p. 650), that the warmest and driest seasons are the most favourable to the yield of wheat. But though wheat requires heat and dryness to ripen and perfect its seed, yet being one of the grasses, it requires, for the development of its stalk, &c., moisture and warmth during its growth as a grass; and its fibre will be deficient, unless the season be favourable from April to June. Thus in the very fine warm season of 1846 the south-eastern counties had rather light crops; yet in moist situations never were the wheat crops better than in that year. In Ireland, with its moist climate, the wheat crop of 1846 was very fine.

We find, then, that the effect of warm dry summers, like the exceptional seasons of 1826, 1846, and 1868, is to ripen our cereal crops, and produce an abundant supply of fine seed: of course, the result produced upon our root and grass crops is injurious, and perhaps never more so than in the present year. To meet this present deficiency of winter food for our stock, great and, we trust, successful efforts are making, and have already been made, by late sowings of green crops; so that there is a reasonable expectation that, by God's blessing, when we arrive at the year of grace 1869, we may still concur in the truth of the adage of the English farmer, that "a warm dry summer never yet was injurious to Old England."

### GROWING CLOVER SEED.

There are several reasons why farmers should grow more clover seed; not the least important is to have plenty of seed to sow. Few farmers will sow as much clover seed, when it is bought at a high price, as when they have raised a good

crop; either some field or part of a field, that ought to be seeded, will have to lie over, or if all land in proper condition is sown, there is often a rather light seeding—"it costs so much for seed." The great need of improving the soil, and the well-known value of clover as a renovating crop, show that this is poor economy. There is more or less lost in the quantity and quality of the crops grown from such seeding; so that, to save one dollar in seed, ten dollars in products are often sacrificed. The best remedy for this is to grow plenty of seed; then, when disposed to seed liberally, the farmer will not be prevented by any draft on the pocket-book.

Another good reason is that clover seed, if well managed, is a profitable crop—more so, in fact, than most farmers appear to be aware of. They do not seem to consider that usually two crops are grown in the year—one of hay and one of seed; and that these crops are often of considerable value—say an average of 1 $\frac{1}{2}$  tons of hay, worth, at 10dols. a ton, 15 dols., and 2 $\frac{1}{2}$  bushels of seed, at 6 dols. a bushel, also 15 dols., making 30 dols. an acre in one season. And these are only ordinary crops; often two tons of hay and four or five bushels of seed (seven bushels have been grown in this way in this county) are grown to the acre, while prices are often much higher, giving from 40 dols. to 60 dols. per acre for hay and seed.

This is the usual way of growing the small kind. The other variety, being a larger and later plant, requires different management. There is not so much of this kind grown, but the price being higher, now and then a farmer makes it profitable. A friend of the writer is quite successful with this variety, his general average being five bushels per acre. Last season he grew forty-three and a-half bushels on eight acres—nearly five and a-half bushels per acre. This seed has probably sold for some 8 dols. or 9 dols. a bushel, which, with the pasture—it is fed close up to the 10th of June, and the seed comes off early in September—makes it a very profitable crop; and this, too, it should be remembered, is grown without any expense for fitting the land or other cultivation.

How many farmers do a large amount of work, in fitting and cultivating land for grain crops, that do not return half the money! And how few are the farmers that make their grain crops realize better returns! The one referred to is a full better farmer than the average, and grows more or less wheat, barley, corn and oats; and it is very doubtful whether any one of these grain crops averages as much money per acre, one year with another, as his clover seed. And yet, while all the grain crops are expensive for cultivation and seed, clover seed, in reality, costs nothing for either, the clover giving a considerable profit in the second year's crop, and improving the soil over all expense for seed and use of land. There is, in fact, no cultivation required; making the land in good condition for wheat or barley is the best for clover seed.

And then, there is no great difficulty in growing clover seed, although many fail, or come short of the best results, because the different operations are not attended to in their proper season. Farmers are careful to harvest wheat and other grain crops in the proper season; but leave clover standing until it is convenient to attend to it. But there is often great loss in this way. Not that the seed that is left is injured, but that a large part is shelled off the heads. The chaff shells off very easily; and when the farmer may think it best to wait a little for some of the later heads to ripen, he may lose a considerable share of the earliest and best seed.

If a good crop of seed from the small kind is desired, the first cutting must be early. When it is as soon as the first of July, there will often be double the seed grown in the second crop, that will be secured if the first cutting is ten days later. Still, but few farmers take pains to cut clover hay early. Often, to save hiring a week or two, the clover stands until the tenth or fifteenth of July, when, of course, the following crop of seed must be light. Although the farmer thinks little about it at the time, yet he has sacrificed a large part of his crop of seed—perhaps made it so late that it will not be thought worth saving, and lost from ten to twenty dollars per acre to save a few dollars for hired help. Each year's observation proves that this is often the case; and no doubt thousands of farmers in Western New-York lose, or fail to realize, hundreds of dollars each every year by such mismanagement with clover and clover seed.—*American Country Gentleman*.

## ON THE CULTIVATION OF THE SUGAR-BEET.

Events of various kinds, agricultural and economical, as well as political—with the former of which we have alone here to concern ourselves—have given a large and prominent, and time alone can show whether it will be or will not be permanent, interest to the affairs of Ireland. Amongst the points thus raised, all of which are interesting, many of them most important, is one connected with the improvement of the agricultural prospects of the island, bearing upon the introduction of what is called a “new industry,” or what would be more properly called a new development of agricultural labour—this is the *cultivation of beetroot* for manufacturing or industrial purposes; these being mainly the making of sugar, if not that of the distillation of spirits. This, in a recent correspondence, with which our readers may be more or less familiar, has been opened up with considerable spirit, but time will show whether this spirit is to be maintained or not. Meanwhile we may here note that, if introduced into Irish farming, it will not, as many seem to think, be newly introduced; for it so happens that the plan has been tried before, and with what success we shall see as we proceed. It further happens that the writer of the present paper was called upon, during the period in which the cultivation of beetroot was carried on in Ireland, for the special purpose of aiding the introduction of sugar-making into the list of her manufactures, to visit the factory at that time set up near Portarlington (at Mountmellick), and to report not only upon its working and its prospects, but also upon the general features of the cultivation of the root itself, with a view to its uses for sugar-making. He therefore deems it possible that by giving here a rapid *résumé* of what he there learned, he may be able to throw around a subject which possesses in itself many points of practical usefulness that degree of interest which is likely to be of some service to those connected with agricultural pursuits. For it is very suggestive that whatever be the result of the extended increase in the use of beetroot for sugar-making purposes, one result of its cultivation must be the “bettering”—to use a graphic, if not strictly grammatical word—of the farming of the districts in which it is adopted, for bad farming and good beetroot crops are quite incompatible. Hence, there will, in the consideration of the subject, this good come out of it, independently of its immediate interest as an Irish question, that many hints useful in root culture generally will be obtained; as what is applicable to the cultivation of beetroot is more or less directly applicable to that of other roots used by the farmer. This much, therefore, by way of not altogether unnecessary preamble. But before going from its “preamble” into the body of the “Act,” so to say, it will be interesting to glance very briefly at the historical points connected with the subject of the application of beetroot to sugar-making purposes.

We have to go back for nearly a century and a-quarter to find the first record of the use to which beetroot was proposed to be put as a source from which to obtain sugar. In 1747, Margraff, a then much celebrated chemist, investigated the root in this aspect, and as the result of his investigations showed that from white beet he obtained six and a-quarter per cent. of sugar, and from other varieties four and a-half. As showing the influence of good culture in the increase of the saccharine properties of the root, we may here point out that the average percentage of roots now cultivated in Germany

is ten and a-half, which often rises to twelve and a-half. By the time Margraff commenced his investigations, several varieties of beet were in cultivation; but for the period of introduction of the root itself as a farm product we have to go back to a still earlier period, and we find that in France it was first introduced in the reign of the celebrated Henri Quatre; and it was highly recommended as a food for cattle by the well-known Oliver de Serres, then the great agricultural authority of the day.

Although, in view of the high price of colonial or cane sugar which then prevailed, and which almost rendered its use a prohibitive, Margraff at the date named above (1747) strongly recommended its introduction in the manufacturing industries of Germany, nothing came either of this or of the investigations which he had made. The project, if project it could in this undeveloped state be called, lay unproductive—quite, in fact, out of sight—till the year 1796; when the still high, if not higher, price of cane sugar caused an apothecary of Berlin, of the name of Achard, to commence practically the manufacture of beet-root sugar. The process introduced by Achard resembled in its main features that of the cane sugar, and it resulted, as may be supposed from this fact, in the giving of a very inferior brown sugar only. There is “nothing new under the sun,” and the proverb appears to be verified in this direction; for we find that Achard drew very special attention, in a letter which he published, on the value of the pulp—one of the residues of the process—as a cattle-feeding material, a material which of late years has been much written about of late as something “quite new.” The efforts of Achard, although not very productive in his own case of valuable practical results, had the effect to draw the attention of the then Republican government of France to the subject, which was to it one of vast interest, chiefly because it was a point of great interest with the nation to do all possible to destroy the monopoly which Great Britain enjoyed in the manufacture of sugar through her colonial possessions. Two small factories, therefore, were established near Paris, at the end of the last century; they, however, languished, and were far more the object of the witty sarcasms and sayings of the lively Parisians than of that interest which a practical people like ourselves take in new things, having a practical object in view. But a master-spirit was about to take the matter up; and, like everything else to which he directed his mind, it was no sooner within his ken and care than a sudden development of its capabilities took place, and one which has been—under circumstances more or less favourable—maintained till now. We refer to Napoleon, and the introduction of his celebrated “Colonial System,” promulgated by decrees at Berlin and Milan, by which he proposed to be independent of everything produced by, or obtainable through, the medium of his hereditary enemy, Great Britain. The question, then, was not whether the beetroot sugar could be made at a cheaper rate, but whether it could be made at all; for the question of price was very easily decided, so far as the consumers of sugar were concerned; for with them it was Hobson’s choice—“this, or none;” for the use of all other sugar was prohibited. Under the fostering care of Napoleon and his colonial system, the trade grew rapidly, and the attention of the most celebrated chemists were closely directed to the perfecting of its details; and so successful were these,

that in due course of time the process was a paying one; the great invention which brought about this happy result being the discovery of M. Fiquier, of the means of rapidly discolouring the syrup by the use of burnt bones or animal charcoal. This was brought out in the year 1812, and by the year 1814 the trade could command a very important character, and in 1820 it may be said to have been permanently established. It will serve little practical purpose—practical, so far as our readers are concerned—to go into the commercial and fiscal history of the manufacture and trade; suffice it to say that, in France alone, the year 1847 saw 303 factories in work, yielding a produce of nearly sixty-two millions of kilos.—or say one hundred-and-fifty millions of pounds avoirdupois; and throughout Continental Europe in the year 1851 the annual produce was no less than 162,000 tons. As regards the agricultural development consequent upon that of the manufacture, take the following fact as most suggestive of the points of interest in which our readers are chiefly concerned. In one of the towns of the department du Nord of France the following inscription is placed upon the gate: "The growth of wheat in this district before the introduction of beetroot sugar was only 122,500 quarters—the number of oxen 700. Since the introduction of the sugar manufacture the growth of wheat has been 146,180 quarters, and the number of oxen 11,500." Which we may thus paraphrase in the words of the well-known farming maxim: "Many roots, much cattle; many cattle, much manure; plenty of manure, abundance of grain." It will be well then, in view of the importance of the agricultural as well as those of its commercial aspects, to glance at the features of so important a cultivation as that of beetroot.

Upon a *prima facie* view of this subject, it may be supposed that the treatment of the soil for the production of a crop of sugar-beet would be exactly similar to that practised in the cultivation of its congeners, the various types of the mangold wurzel, for fattening cattle. It is very true that the same mode of culture will in both cases succeed, so far as to produce large and small crops of roots, according to the degree of labour and expense for manure bestowed upon them. But, independent of this, there are questions respecting the production of the sugar-beet that render it necessary to deviate from the ordinary culture of this class of plants; and we think we cannot do better than to follow the instructions and observations given in the appendix to Sir R. Kane's report, which embodies the mode of cultivation practised on the Continent, where the experience of sixty years has been modified by a series of experiments of highly scientific men, by which the saccharine properties of the beetroot have been greatly increased, and its quality improved.

The soil best suited to this plant is a rich loam, inclining to a clay rather than a sand. No peat soil is fit for it, and it should be free from lumps of clay or stones. The subsoil should be neither a stiff clay (unless subsoiled and drained) nor a sharp gravel; and the soil itself should be deep, well cultivated, and thoroughly pulverized. Land newly reclaimed is unfitted for culture of the sugar-beet. The bulb should be as much covered as possible during its growth, because those portions above ground and exposed to the atmosphere contain no sugar. Perfect cleanliness from weeds is essential to the well-being of the crop; and the benefit of keeping the soil open by frequent hoeing or stirring has been found to be very great.

With regard to manure, it is better that none should be applied *immediately* to the crop; but if rich nitrogenous manures—such as farmyard manure, guano, &c.—are used, they should be applied to the previous crop, so as to be well decomposed and incorporated with the soil; or

it may be laid on in the previous autumn or winter, in which case, by lying in the soil during the winter months, it would undergo the same process. No salt or soluble saline substances should be applied, nor nitrates that would form them. Ashes from wood, peat, coal, &c., may be employed, and bone-earth as well. Lime is always good, and calcareous soils seems to be the best adapted for this and all other roots. Green manuring is always attended with success. In this case the land should be heavily manured in the autumn, and sown at once with rape or some other plant, and ploughed-in in the spring.

We have referred to M. Kœchlin's method of raising crops of beetroot, by which he not only obtains a large produce, but the proportion of sugar or saccharine is greatly increased. Kœchlin's plan is to sow the seed in March on a highly manured seed-bed, sheltered from the frost; and at the latter end of April or the beginning of May to plant them out in rows, twelve or fourteen inches from each other, and ten or twelve inches from plant to plant, by which means he obtains double the weight of small roots, and an immense increase of the per-centage of saccharine matter. We believe that M. Kœchlin has attained the large amount of saccharine he announces (17½ per cent.) both by an attention to the quality of the manure applied, and by the reduction of the size of the root. Strong manuring increases the nitrous elements of the beet, and renders it much more difficult to extract the sugar, whilst the juice is deteriorated in quality.

"The influence of manures," says Mr. Sullivan, "on the quantity of nitrogen is strikingly exemplified in these tables [inserted in his work]. Farmyard manure and guano appear, as a general rule, to increase the quantity of albuminous substances. This is especially remarkable in beet grown upon loamy soils, but is not so apparent in those grown upon heavy clays ....., the effect of the manures being masked by the influence of the soil. The beet grown upon clay soils grows to a large size, and is, as we have remarked already, more watery than that grown upon rich loams. The effect of this is, to lower the per-centage of nitrogen and sugar in the raw beet; but the per-centage in the dried is, to a great degree, uninfluenced by these causes; and accordingly we find that in such cases also, the effect of heavily manuring with farmyard manure and guano is to increase the proportion of nitrogen. Sulphate of ammonia appears to have the same effect; ....., nitrates, on the contrary, do not appear to affect the per-centage of the organic nitrogenous constituents, but are rapidly absorbed by the plants, and will be found in the juice, along with the sugar. The composition of beet grown upon 'red bog' is curious, as showing that beet grown under such circumstances, or indeed in all land abounding in organic matter of a peaty character, appears to extend its energies in the production of cells, containing an exceedingly dilute juice. Saline manures are not proper, because the presence of saline substances in the juice lessens the proportion of crystallizable sugar. Beet grown near the coast, when it is exposed to the saline exhalations of the ocean, is less profitable for sugar-making than that grown more inland. In all cases, autumnal manuring is superior in effect to spring manuring, whether it be for beetroot, turnips, or any other crop."

M. Blanquet, as quoted by Dr. Sullivan, states that "beetroot grown under such circumstances, although they may yield sugar in abundance in the commencement of the season, are worked with difficulty after being kept a short time. .... We think we are justified in saying no good farmer ought to manure his land with fresh manure in spring, whether his object be to sell his roots

for the manufacture of sugar, or employ them for feeding cattle."

With regard to the cost of cultivating the sugar-beet, the entire process is so similar to that followed for the mangold wurzel, and this is so familiar to almost every English farmer, that it is scarcely necessary to refer to the particulars. Mr. Sullivan took great pains to ascertain this point, both as relating to Ireland and to England; and he found that, with one exception (that of the estimate of Lord Talbot de Malahide, which was £10 ls. 8d. per acre, *after* deducting £2 for the tops\*), the amount in the two countries is nearly the same—say, from £5 10s. to £7 10s., exclusive of rent and taxes. The process followed by Köschlin—that of planting out by hand—would be much more expensive; but the large increase of the weight of roots and their superiority in point of the proportion of saccharine matter would far more than make amends for the excess. Another advantage would accrue from that method in the earlier maturity of the crop, from having the plants ready to be set out at the time when on the common plan the seed is generally being sown, by which the young plants have the full benefit of the spring showers, and become strong before the dry season comes in. The advantage also of having the crop matured at an early period of the season enables the manufacturers to commence operations earlier, and gives the grower the return for his outlay long before the roots raised in the ordinary method are ready. The planting-out of the young plants can be managed by women and young people, provided the latter have a careful and competent person to superintend them.

The cartage of the beetroots to the factory will not be much more expensive than the ordinary carting to the homestead, and it can be performed when the other work of the farm is slack. Mr. Sullivan obtained considerable information on this part of the subject; and from the opinion of experienced men both in Ireland and England he came to the conclusion that 6d. per ton per mile was a full average expense attending the delivery; or, if the factory is five miles distant, at 2s. 6d. per ton. The entire expense therefore of supplying beet root at the factory, if five miles distant, would be from 8s. to 11s. per ton, according to the amount of the produce.

The tops or foliage form an important item in the value of the crop of beetroot. If consumed by cattle on the spot, it is estimated at about 20s. per acre on a crop of 20 tons, or 1s. per ton. In France and other Continental countries the tops are preserved in pits like those for potatoes, salt being sprinkled plentifully over the layers as they are deposited. In this way they will keep any length of time, and are eagerly devoured by cattle. It is said that cows fed on them give a large increase of milk. There are few English farmers, however, who would take the trouble to preserve them in this way at the time when so many other operations of the farm are pressing upon their attention. Otherwise, the salt applied to them is certainly useful, as well as necessary, and promotes the health of the animals that feed on the tops; but salt can be given to them in other forms; and the difference in the value of preserved tops and those consumed on the field, or ploughed in as manure, is so small as not to form an object of attention. The raw leaves are estimated at 3s. 4d. per ton; and as a portion of the bulb (that part not covered by the soil) is cut off with the foliage because it contains no sugar, the weight will be greater per ton of roots than from the mangold wurzel, according, however, to the quality of the soil and the

species of the beet, some having a larger amount of foliage than others.

With regard to the comparative profit of cultivating beet against wheat, a very slight statement will show that on an average of years the former is superior to the latter as a remunerating crop. In his estimate on this head, Mr. Sullivan reckons that of beet at 15 tons per acre and 15s. per ton, and 4½ tons of tops at 7s. 6d. per ton, making together £12 18s. 10d., from which he deducts £5 6s. for expenses of cultivation, leaving a profit of £7 12s. 10d. The wheat he estimates at 6½ barrels of 20 stones each, at 22s. per barrel. This is equal to 30 bushels at 37s. per quarter, or £7 3s., to which he adds 1½ ton of straw at 15s., or 18s. 9d., giving an aggregate of £8 1s., from which is deducted expenses £2 7s., leaving a profit balance of £5 14s. 9d. Deducting this again from the profit on the beet of £7 12s. 10d., it gives a balance in favour of the latter of £1 18s. 1d.

This estimate is evidently too low in every respect for the present time and for England, and we shall therefore take the beetroot crop to be 15 tons per acre at 18s. per ton, and the wheat at 3½ qrs. at 50s. per qr., which is probably what the average price will be in future. Thus,

	£	s.	d.
15 tons of beetroot at 18s. per ton	...	...	13 10 0
4½ tons of tops at 7s. 6d. per ton	...	...	1 13 9
			<hr/>

This leaves a balance in favour of beet	...	...	2 11 0

and when we take into the account that wheat requires a whole twelve month to arrive at maturity, and frequently a previous fallow which adds the expense of another year's tillage without an additional crop, there will be no question of which is the most profitable to the grower. But this consideration is not regarded by the continental farmers, as they grow beet and wheat alternately, and find the root crop an excellent preparation for the wheat, especially when the tops of the beet are ploughed in as manure, which is sometimes practised. The beet, too, arrives at maturity in four or five months, and, if properly tilled, so as to give it a deep seed-bed well comminuted, is less liable to the casualties of the season than either cereal or turnip crops. It will be understood that the seeds or plants should be cultivated on the flat, the object being to obtain *numbers* rather than *size* of roots: ridges would require much more space, and would frustrate rather than promote that object.

But we have stated the crops of beet very low at 16 tons per acre. If we suppose that the plants will be planted out, say the rows at 16 inches and the plants in them at 12 inches apart, there being 43,560 square feet in the acre, and the four inches in the rows taking off one-sixth, there will be 36,300 plants on the acre, supposing again there is a full crop. If, again, we assume that the average weight of roots is 3lbs. each the weight of the crop will be 36,300 × 3 = 108,400lbs., or nearly 48½ tons. Or if we estimate the average weight at only 2lbs. the return will be one-third less, or 32.2-5th tons. This calculation will show the great importance of

\* It ought to be stated that in this case the produce was 50 tons per acre, and the land was manured with 45 tons of stable-yard dung.

paying the utmost attention to the planting of the seed or the roots; the latter plan being by far the best and most certain plan of putting them in, and the extra crop being amply sufficient to cover the extra expense of planting.

Even the average of 15 tons per acre, which an English farmer may safely calculate upon, is much more than is obtained on the continent. In France the official statistics gave the average of the whole country at 10·89; but M. Boussingault makes it for several years 10·50, and M. Ruville, for seven years, only 7·16. This latter, however, was taken as the average of Lorraine and Champagne, the most sterile provinces in France. In Northern Germany the average is 10·50 and in Southern Germany 9·30, according to the report of the Prussian Government in 1847. The following table, however, by a French statist, M. Moreau Jonnés, gives a more liberal view of the product in France:—

Average produce of sugar-beet in various Departments.			
Nord .....	tons 16·76	Rhone .....	tons 11·29
Finisterre .....	16·52	Hérault .....	10·69
Bas Rhin .....	13·81	Aisne .....	9·42
Pas de Calais .....	12·89	Haut Rhin .....	8·66
Seine .....	12·69	Cher (Boussingault) ...	15·60
Ardennes .....	11·79		

We come now to the question of the probability that the introduction of this manufacture into England will be attended with advantage, not only to the agriculture of the country, but to the manufacturer as well, because as purely philanthropic motives are out of the question, that of profit to the latter party embraces the whole object in view. It is, therefore, of the first importance to weigh well the circumstances by which the question is surrounded, in their bearing upon the subject of profit and loss to the manufacturer.

In an economic point of view manufacturers are divided into two classes—those which are employed on raw materials of foreign production, and those employed on articles of native produce. In the former we may reckon the cotton and silk, in the latter the linen, woollen, and many other materials, both textile and otherwise. It requires no argument to prove that the latter must, as a general principle, confer a much greater benefit on a country than the former, provided the raw material can be produced as good and as cheaply as it could abroad, and the manufactured article itself can also be produced equally good and cheap as it could be supplied by the foreigner. With regard to the raw material in the case of beet-sugar, enough has been shown to prove that English agriculture by its advanced position, its intimate knowledge of the peculiar cultivation it involves, the adaptation of the soil and climate, is perfectly adapted to supply it of the best quality, and at a price to meet the requirements of the manufacturer, without throwing the land out of course or in any other way interfering with the regular routine of the farm. We have, therefore, only further to consider the case of the manufacturer in regard to the competition he will have to encounter and his power to produce an equally good article at a price to meet it.

It is well known that hitherto our supply of sugar has been obtained from the West and East Indies, the Mauritius, &c. The first of these includes a large amount of *slave-grown sugar*, which our legislature most iniquitously allows to be admitted at the same duty as that from our own colonies. This is a glaring dereliction from all the moral principles hitherto maintained on the subject since 1832, and which ought to have been specially maintained as against Spain, who has cost this country at least thirty millions sterling to prevent her carrying on the slave trade, for which she was paid a large equivalent in money. This, it is true, has no further to do with the question before us than that it increases the amount of competition which the manufacture of beet sugar will have to meet. In

other respects, we will never omit a favourable opportunity of exposing the injustice, and, we will add, impolicy of thus pandering to the base and inhuman practice of slavery and the slave trade in foreign countries, after abolishing it in our own colonies. The claim that Spain had on England, not of sympathy and encouragement, but of indignation and disgust at her perfidy and meanness in accepting a large sum to give up the trade, and then, so far from fulfilling her engagement, continuing the inhuman practice with increased activity up to the present moment, condemns the Spanish Government to everlasting infamy and contempt, and our own Government is deeply involved in the same condemnation. We shall say no more, except that we will never omit to express our sentiments on this national crime whenever our subject naturally leads to it.

The competition then, that the manufacture of beet sugar will have to encounter, is chiefly that of the British and foreign West Indian colonies; the question, therefore, to be solved is whether the beet sugar is able to sustain this competition both in respect to quality and expense of cultivation as an indigenous against a foreign production?

We should be justified in saying that this question has already been fully answered by the progress of the manufacture on the continent, and especially in France. In this latter country, so far from being compelled to sustain it by a protective duty on foreign-made sugar, the Government gradually transferred the protection from the beet to the colonial sugar, by removing it from the latter and imposing an equal amount (5 francs per cwt.) on the former; and so far has this change been from destroying or injuring the manufacture that it has largely increased, say from 51,110 tons in 1847, to 275,000 tons in 1866, and 215,000 tons in 1867 and 1868; and the same increase has taken place in other countries, more particularly Russia. We have already referred to the above statistics, and if we repeat them it is with the view of showing that the success which has attended the manufacture in France with all the aids of science and skill has had a reflex action upon the West India planters, who have been compelled by the force of circumstances to adopt similar methods of extracting the juice from the cane and reducing it to crystallised sugar; but that with these additional aids and a greater spirit of enterprise, the natural effect of competition, the indigenous article is in the ascendant. The reason of this is obvious: there is the freight and other expenses of transit, the brokerage, the leakage on the passage (15 per cent. on sugar and 20 per cent. on molasses), with a variety of other drawbacks from which the beet sugar is wholly exempt. In the West Indies the canes must be cut and operated upon without a day's delay, as soon as they are ripe. If not cut then, the juice hardens and it is difficult to be extracted; and if the juice is not instantly boiled down it is liable to ferment and turn acid, which prevents the proper crystallisation, and thus injures the quality of the product. This circumstance renders it necessary to employ a great number of hands, at extra wages, rendering the manufacture exceedingly expensive compared with what it was during the existence of slavery, although the men work harder. On the contrary, the beet-root can be stored, and by that means the manufacture may be spread over at least four or five months, and if *dried*, as is practised on the continent, can be continued throughout the year if the quantity of beet is large enough. But if the evidence given by the West India planters before the Committee of the House of Commons in 1847 is to be depended on, the average expense of all the British colonies in the manufacture of cane sugar (Muscovado), was 19s. 2d. per cwt., classing them as follows:

	a.	d.
Jamaica ... ..	22	7
Guyana... ..	25	0
Trinidad ... ..	25	0
Barbadoes ... ..	25	4½
Tobago ... ..	17	0
Antigua ... ..	15	4½
St. Kitts ... ..	16	2
Grenada ... ..	16	2
St. Vincent ... ..	19	2
Average ... ..	19	2

And this account was confirmed by that in p. 17, giving the statement of the whole crop of the West India Islands in the year 1847, which involved an aggregate loss of £170,000. No doubt, in most of the islands, the planters have both lessened the expenses and increased the product of sugar by the adoption, so far as was useful as adapted to the cane, of the mechanical and other inventions of the French beet-sugar manufacturers; but, owing to the hard, woody nature of the cane, there is an insuperable difficulty in applying an equal and continuous pressure in the extraction of the juice; so that, although the cane contains eighteen per cent. of saccharine matter, not more than seven or eight per cent. is obtained, which is about the quantity obtained by the beet-sugar manufacturers from that root. There is also no difficulty in the extraction of the latter, its soft, watery, and pulpy nature allowing it to yield to an equal pressure of the hydraulic press. The expense of labour in the case of beet-sugar is estimated at £10 10s. per ton, exclusive of rent, interest of money, insurance, and duty.

Nor is it the least advantage in favour of the beet-sugar manufacturers that there is no delay in the realisation of their returns. They may receive the roots in the morning; and by the next day the sugar may be ready for the market, if necessary; for such is the improvement in the processes, that what formerly occupied many days can now be effected in one day. We have seen loaf-sugar, the product of the factory at Mount Melick, in Ireland, which was made from the juice that had been pressed from the root the same day. The separation of the molasses from the crystallised sugar is effected in a few minutes by the centrifugal machine. The black, semi-fluid mass is put into this machine, which is then made to perform seven hundred revolutions per minute.

By this rapid movement the mass is thrown against the wire-gauze with which the machine is lined, with such violence that the molasses are forced through it, and leave the perfectly white sugar in the machine. We have seen this effected in less than five minutes. Another improvement is the introduction of a current of atmospheric air into the evaporating-pans, by which evaporation is artificially kept up at a low temperature, and greatly accelerated; whilst, as a collateral effect of the same process, the sugar is divested of the flavour of the root, which previously was the principal objection to it.

We have referred to these improvements in the manufacture without any intention of going into the general processes, but to show the increased facilities for sugar-making that have been discovered, and that those who may embark in the manufacture in this country may have the full benefit of these discoveries, without the trouble and expense attending the experiments by which they were perfected. Vast sums have been expended, and years of reflection and experiment employed by scientific men, in bringing such improvements to bear, of which the new-comers may at once avail themselves. All the processes in this manufacture are mechanical, nor is there anything relating to it but what any person of common understanding may readily make himself master of.

It now, however, remains for the intending growers of the beet-root in different parts of the country to make their experiments in regard to the applicability of soil and climate for the production of a sufficiently sacchariferous root, which, in fact, is a vital question. At the same time, deep tillage—subsoiling if possible—thorough-draining, and a complete pulverisation of the soil are indispensable operations for the production of a first-rate crop of sugar-beet, as they are also in the case of all other root-crops. Small roots (under three pounds) rather than large, numbers against individual weight, must be the aim of the growers; and, by extra care in planting, instead of sowing, it is certain that not only a more valuable, but as heavy, a crop may be obtained, as is done on the Continent. Following these rules, which are nothing new, though too much neglected, in the United Kingdom, there is no reason whatever for supposing that the soil, climate, and other natural phenomena are not as favourable to this manufacture with us as those of any part of the Continent.

## THE POTATO CROP—ITS PRESENT STATE.

BY A PRACTICAL FARMER.

Now that this unexampled early harvest is pretty nigh secured, the interest of the country is mainly centred in the potato crop, and not without reason. I am very reluctant to sound an alarm, but truly our somewhat promising crops are just now in a peculiarly anomalous condition. The early plantings obtained the advantage of the fine growing season we had from March and April up to about the middle of May, when the drought began to tell upon the crops; a few hopeful showers fell, but from the 30th of May to the beginning of August we were without scarcely a drop, and the months of June and July probably the hottest months ever known in the country. Of course, nearly all the potato crops ceased to grow, or progressed very slowly, and the latter planted crops were badly moulded up, owing to the cloddy state of the soil; this still farther retarded their progress, letting the drought into the very tubers. Everything was

done that could be thought of, to promote their growth, but to no purpose, and many crops succumbed on the heavy loams and clayey soils; so much so, that the rows could not be discerned on passing, and upon every crop throughout the country, at least every crop with which I am acquainted or have heard of, the drought and heat have had the disastrous effect of prematurely maturing the tubers, and particularly in what few tubers had made material progress in the late planted crops. The late beautiful rains have caused them to put forth abundance of fibres, from which young potatoes are growing most luxuriantly, and the haulm has the appearance of a first spring growth, growing rapidly and luxuriantly. The early planted crops were never more promising up to the middle of June, when they also nearly stopped growing. Up to that time they had made excellent progress, and many fine tubers are now to be found; but unfortunately

the same premature maturity took place very extensively, and the late fine rains are now producing the like disastrous effects as upon the late plantings. I have this day (August 19th) spent some time in examining various crops of both early and late plantings, and all alike, if not in equal degree, have commenced a second vigorous growth, and young tubers from the size of a pea to that of a large walnut or even an egg are to be found everywhere, and from all varieties of potatoes; at least I found it so in those I examined, i. e., Regents, Flukes, Rocks, and Kerry blues. The haulm in almost all cases presents the most healthy and prosperous growth. In one or two fields that I have seen where the haulm has partially decayed the tubers are in a much better state, and are good in quality. Our potato growers are all in fear and consternation; the expensive growth of this season is unexamined; the cost of seed, the culture, manurings, and planting amount to nearly £20 per acre (a grower this very morning assured me his cost was fully that), and then to have a failure is very trying. There are many speculators in the market, and all are looking out for the best early-planted crops, for which they are giving high prices, providing they are fairly matured in haulm and tuber, and can be harvested immediately; £30 per acre appears to be the current price. The great fear is that this second growth will greatly injure, if not totally destroy the tubers of this summer growth, in like manner as the original set or planted tuber. This is one of my fears; and I feel assured that if they are not destroyed, they will be greatly deteriorated in quality, and much reduced in weight. I am a grower of about eighty acres this season, and my anxieties have been much aroused by my examination to-day. I have conversed with several growers, and no one can suggest a desirable course. Some are trying to harvest their crop in all its full luxuriance. This can only be locally and partially done. Others are cutting off, or pulling up the haulm. This may be right in some early planted and matured crops, but woeful waste in the late ones. It may retard the growth, but it will not stop it, any more than the tuber first planted in the spring. The tubers are, in fact, as planted, and are growing, and will no doubt put forth fresh haulm ultimately, or decay in the ground. Others are disposed to let all alone, and await the result. I am inclined to the latter course; in fact they won't keep in grave if they are taken up, and all cannot go into consumption at once. For the main crop there is no alternative; growers must wait patiently. Better decay in the field than spoil in the grave. Each man must judge for himself. If a portion can be harvested without great risk, it may be desirable to take them up. Undoubtedly, the more young tubers produced, and the larger growth they attain, must be at the loss of the present crop. It is a very trying and perplexing difficulty. I trust that our agricultural and other papers will take up the case, and that all the information that can be gathered upon a matter so vitally important, not only to the grower, but to the consuming public, will be at once diffused throughout the country, so that something may be done either to mitigate the evil or suggest what should be done. I hope men experienced in such matters will at once take the subject up, and give us their views and suggestions. It is unquestionably a matter of vast importance to our country, and I wonder it has not been brought more pointedly or earlier before the public. I abhor panics, and fear anything leading thereto; but everything that can possibly be done to allay fears, ought to be openly discussed, and the conclusions promptly acted upon. There is danger in the potato crop—great danger! How can it be averted or provided against? It cannot be otherwise than a partial failure, as it now stands. The drought and second growth of the crop determines that. The great

question is the best manner of securing the imperfect crops we have. My object in the main is to engage all parties to aid in this important question, as every day adds to the country's difficulties as respects food for the population. We need the collective wisdom of every one versed in potato management. At all events, we have a good wheat crop; plenty of bread. That's one of our greatest and best blessings; but here we must, with trembling, stop. We have no other substantial resources, or indeed average sources of food for the substance of our people. Our spring corn and pulse crops are bad; our root and green crops for cattle and sheep are bad; our supply of cattle and sheep for meat is very short and deficient in condition, and no winter food to fatten them; our markets are partially closed against the introduction of foreign stock; meat has considerably risen in price; our potato crop is in a most precarious state, and at best bad; our garden produce is eaten by fly, &c., and very bad. I have before me the testimony of 198 competent judges of the state of the potato crop in July last throughout England and Scotland: 93 give an average crop, 101 under average, and 4 over average. I have also the testimony of 81 competent judges throughout Ireland, just published: 39 speak favourably, 42 speak unfavourably, and scarcely any of the returns allude to this second destructive growth; indeed, it had scarcely been developed when the 198 returns were sent in, but one or two of the Irish returns allude slightly to it. I have not seen returns from the Continent, but I have no doubt that all crops in a similar latitude to this country are also affected. My hope in penning this paper is to excite universal attention to a subject so important.

#### FODDER.

The Rev. Mr. Vicary, of Wexford, writes as follows to the *Times*:

In consequence of the failure of the hay crop, owing to the unprecedented season we are passing through, the burnt-up state of the pasture, and the light yield that the mangold and turnip must give this year, it becomes a question of much importance to know how the agriculturist may be able to supplement his slender stock of fodder.

There has been a plentiful supply of rain, and in a month or six weeks the pastures may be expected to supply some food, but in very dry lands the herbage can hardly do more than re-establish itself.

In these circumstances it should be extensively known that we possess in our woods and hedges a food of which all cattle are extremely fond, upon which they fatten and flourish wonderfully, and the gathering of which forms one of the regular crops of the northern countries of Europe. I refer to the common ash tree, *Fraxinus excelsior*, of our woods and coppices.

In Sweden, Finland and Denmark, before the advent of cold weather, which impairs the succulence of the leaves, every frond and leaf is collected from the boughs of the ash, of which some are immediately used as food for the cow, horse, and pig, and of which all eat with avidity. The remainder of the leaves—the main crop—is placed in empty houses, a little salt being scattered among them, or placed upon slightly elevated stands in the rick-yard, using also the stipulated quantity of salt, which are then securely thatched over as security from the rain. Thus treated, the ash fodder lasts through the winter and spring, and at this period, if deemed requisite, is boiled or steamed with the addition of some bran.

Every farm may not have its ash coppice, but those who possess this tree should know, under present circumstances, its valuable properties, and proceed at once to utilize it for present and future use.

Thousands of tons of this esculent could be collected through the country, and the present time, when the sap is vigorous in the leaf, would be desirable for harvesting the crop; but it can be used as required, care being taken to collect the main crop before frosts or cold winds have set in.

## LEICESTERSHIRE FARMING.

Kirby Mallory was the earliest home of pure Short-horns in the county. Mr. Wetherell, a banker in the North, came there in 1813, and sold off in 1820. Jobbing's Rockingham (560), Denton (198), North Star (460), a son of Comet's (155), and Robert Colling's Major (398), were his chief bulls. Mr. Smith of Dishley, a joint owner with the Hon. J. B. Simpson of the bull Lancaster (360), was another early improver; and so were Mr. White of Cotes and Mr. Raine, who both used Kirby Mallory bulls. In later days, Lord Berners kept a large herd at Keythorpe Hall, and won several prizes—more especially with Hassan (9,193)—at the county shows. His lordship's herd was derived principally from the Marquis of Exeter's, Mr. Dodd's, and Mr. Dudding's blood; and was sold off in the August of 1852, when Mr. Packe, M.P., purchased largely. Earl Howe has stood for nearly 30 years on a rare milking tribe—the Bright Eyes—the ancestress of which (Belle) he purchased from Mr. Moore of Appleby. His lordship has had several other cows and heifers from Rose of Cotham, Wilkinson of Lenton, Parkinson of Leyfields, Crosland of Burbage, and other well-known herds. Second Duke of Oxford (9,046) was bought at the Kirklevington sale; and Lord Exeter's Simon (5,135), Mr. Parkinson's Vanguard (6,633) and his Duke of St. Albans (6,944)—both of the Gwynne tribe—Col. Kingscote's Guardaman (14,656), Lord Feversham's Duncombe (11,402), and Mr. Langston's Lord of the Herd (20,204), have all been at Gopsall, and left many useful bulls among the tenantry.

Mr. Stokes of Kington's large herd, which was principally descended from Kirby Mallory and Lenton tribes, was sold off a few years before Lord Berners', and much of it was taken out of the county. Mr. J. S. Crosland, a large local winner with his Selim (8,545), Salisbury (10,779), and Mazeppa (10,520) stock, had a good herd at Burbage, near Hinckley. It was also at the sales of Mr. George Townshend, in this neighbourhood, that the Duke of Devonshire, Mr. David McIntosh, Mr. Charles Howard, and Mr. R. W. Saunders laid the foundation of their Princess, Gwynne, and Blanche tribes. General Sale (8,099) and Old Rowley (15,020) were his most celebrated Princess bulls; and his "Old Leicester breed of cart-horses," headed by Iron Duke, brought him not a few show honours.

Mr. Bosworth of Dishley's Red Cross Knight (20,637), Stanley, and Ermine—all winners at the Sparkenhoe Show, where The Knight took the prize for the best Shorthorn in the yard—were by bulls bred by the late Mr. Packe, M.P. Messrs. W. and H. Gill of Burton-on-the-Wolds, Mr. E. Power of Barleston Manor, Mr. Shipman of Waltham, and Mr. Snodin of Stonesby have all "gone in for pedigree." Mr. Herrick of Beaumanor is seldom without a well-bred bull, and Thorndale Troutbeck (22,307) has been in residence; while Col. Arthur has introduced Young Friar (19,797) and St. Patrick (20,776); and Mr. Ivens—one of the very few men who have bred Southdowns in the county—takes his stand on Earl of Lancaster (21,648).

The late Mr. Packe, M.P., began to form his herd about 1851, chiefly from Lord Berners' stock; and by using good bulls, his steers were soon highly spoken of by the butchers, and produced a paying bull-calf trade. In 1860 some of the inferior sorts were drafted out; and new blood was used—to wit, Mr. Wetherell's Stanley

(17036), Mr. Carr's Don Windsor (19585), and Count of Windsor (21498). At Christmas, 1866, Mr. Packe was first in the old class at Smithfield with a white ox; and after his death the herd was sold. It mustered 84 head, of which 34 were two-year-old, yearling, and calf steers, with good pedigrees on both sides. The cows were mostly descended from Lord Exeter's, Mr. Maynard's, Mr. Torr's, Rev. T. Cator's, Mr. Marjoribanks', Mr. D. Smith's, Sir C. Knightley's, Mr. Surtees', Sir C. Lambert's, Mr. Cruickshank's, and Col. Towneley's herds; and the Waraby bull England's Glory (23889) was in residence. The 84 head averaged £37 11s. 10d.; and the highest prices were, for cows, &c.: Wharfedale Butterfly (Col. Towneley) 110 gs., Auricula (Mr. Macintosh) 71 gs.; bulls, Towneley Butterfly (Col. Towneley) 130 gs.; and Windsor Duke (Mr. Jordan) 110 gs.; while the capital three-year-old steer Fortune made 52½ gs.

Mr. E. H. Cheney, of Gaddesby Hall, has only begun very recently with pedigreed cattle, and previously bought cattle for feeding from Ireland and the fairs all round. At the last Burghley sale, in 1867, he first "smelt blood," and bought, with his friend Mr. Angerstein, M.P., two or three heifers apiece. At Havering Park he went in for General Napier, of the Princess blood, at 80 gs., which has grown into a very fine bull; and during the following fortnight he bought five at Messrs. Bland and Barber's, including Bonquet (66 gs.), of the Foggathorpe, and Bright Eyes 2nd (61 gs.), of the Wild Eyes tribe. At Mr. Sheldon's, the same autumn, he bought Lady Blanche (56 gs.), and also added to his store Princess Helena (75 gs.) and Autumn Rose (66 gs.), of the Chriap's Duchess line, from Mr. Brampton's. Then followed a few private purchases, including Maynard's Rosamond, which had been sold at Burghley, and another of the Foggathorpe tribe. General Napier satisfied him so well, that at Mr. Adkins's last sale he gave the top price (345 gs.) for Princess, of the same blood, and followed it up with 145 gs., at Rowfant, for a daughter of Fancy. At Mr. Clayden's he also gave 120 gs. for Brilliant, of the Blanche blood; and in fact, for some time past, Mr. Strafford's best sales have seldom lacked his commissioner.

All these efforts to introduce and keep good blood in the county have hardly been met with corresponding spirit, and there is, we fear, too much truth in a complaint, which we heard more than once, that "a half-crown bull flourishes while a crown bull starves." Black noses are plentiful enough; but, taking the dairy cows all round, they are superior in their looks to the Cheshire ones, as far as breeding goes. Some of the large dairy-farmers get rid of the calves they do not want, at £1 a-head when a week old; while others keep them and run them over the seeds. The Duke of Rutland's property is not cheese-land; but the farmers make butter and keep their calves till two off, and then sell them at Grantham and Melton Mowbray to be finished off. Those who don't mow, and have no plough land, are either obliged to purchase beasts at the latter end of the year, and send them out for the winter to straw with cake and turnips in Lincolnshire, or trust to buying what they require in the spring of the year. Others have no hay, but only straw and turnips. Barley-meal is very much used, and so is palm-nut-meal, which is mixed with chaff for the beasts and chaff and corn for the horses. It has also been found very useful in keeping sheep up to the mark in the

winter; but, like the beasts, they "look at it twice," and never seem to take to it with hearty good will. Bean-meal and oats are a great article of consumption in some dairy herds; but oil-cake is rather eschewed, as it is thought to injure the pastures for cheese-making. Farmers like to have their dairy-cows and bullocks tied up by December, and like it all the better if they get their notice to quit by a fall of snow, which sweetens the ground and lets hounds run.

A constant draft goes on in the dairy-farmers' byres, and many of the heifers are dried off and stall-fed for two or three months before going to the Leicester, Derby, or Fazeley markets, where "a neat cutting one," as at New-castle, is always sought after. On the Hinckley and Bosworth side these dairy drafts pretty nearly supply the wants of the feeders, and the drape cows which are fed off round Melton Mowbray nearly all go to London. Towards Loughborough the farmers generally make up their winter lots from the Derbyshire dairies, and West Highlanders from Brough Hill, Yorkshire cattle from Derby and Northampton fairs, and "Lincoln reds" from over the Ouse help to swell the ranks.

We found the union of beef and mutton admirably exemplified at Mr. Everard's, of Narboro' Woods, who has one of the largest milk dairies in the county, and very spacious and excellent outbuildings. He can tie up one hundred cows, and has open yard room for forty store beasts as well. From seventy to eighty cows are always in milk, and the rest are either feeding off or coming in. Mr. Everard picks up most of his cows and heifers in-calf about home, and the rest in Leicester market. His general plan is to keep them for one season, and dry them off for two months, during which they are prepared for the butcher with light corn, flour, barley, cake, or oats for variety, along with barley-straw, cabbage, pulped turnips, and mangolds. Palm-nut meal was once in very general use, but it has been discontinued. Great stress is laid on brewery grains, which not only force the milk-veins, but produce beef as well. These grains are carted about five miles from Leicester, and are then stored in six large pits, nearly nine feet deep, and capable of holding from five to six hundred bushels a-piece. A layer of spent hops is put over them, and they are hermetically sealed with layers of sand and clay. By such management, they will easily keep for twelve or fourteen months. They are given to the cows when the grass is done, or fails in summer; and the usual allowance to each cow is a bushel at twice. As much as 600 bushels of them, 10 cwts. of cake, and 10 qrs. of corn have been consumed weekly *inter alia* by the sheep, cows, pigs, and horses on the farm. Mr. Everard has about 450 acres in hand, through all of which he has put the plough at one time or another. He dresses his pastures for the dairy cows with half-inch bones, and uses all his liquid manure on the mowing ground. His practice is to mow clover, instead of vetches, and he devotes about twenty acres to it. Rape and mustard are not in his rotation, as the land is too heavy to tread with sheep; and he relies most on his drumhead cabbage, which does full justice to its very heavy manuring. His flock consists of about a hundred ewes, of which sixty are put to the Leicester, and forty to the "Shrop." The hogs begin with cake in October; and when no roots are to be got, they have brewery-grains, and ground corn as well; and he sold out his fourteen-month cross-breds, one year, at 58s. 8d. each.

Stilton and flat or new milk cheese form a great staple of Leicestershire farm produce. The manufacture of the former is confined to a small district round Melton Mowbray, and a portion of Top Leicestershire; while that of the latter is spread far and wide, and more especially over the south-west side of the county, with

Hinckley, Bosworth, Ratcliffe, and Cadeby as its strongholds. The balance of evidence is in favour of the belief that this part does not make so much cheese as it did formerly, and that the high prices of wool and meat have induced farmers to graze more. Sheep districts suit cheese-making better than the rich bullock land, as the latter has too much fatty matter in it, and the cheese will consequently not unite. The attempt to salt tainted beef would not be one whit more discouraging than to try for truth of texture and colour in cheese, where too much artificial manure has been used. In truth, it would be dear at twopence a-pound, and the factors would throw it up. Again, if cows are put upon clover, it pluffs the cheese, and makes it quite unsound. A little bonedust or compost may answer upon the pastures; but some dairies have been quite spoilt by over-improving grass land, and there is much truth in the Arley Hall lyric:—

"A bull fed on rushes, depend upon that,  
Is worth more to the dairy than two that are fat."

We find from the records of the Leicester October Fair of 1807, that only 200 tons were pitched, and that it was "sold from 58s. to 60s. per cwt. plain and 62s. to 63s. best coloured." The general average was 60s. for new milk cheese, and the county was then considered quite equal to 1,500 tons a-year. At the last May fair Mr. James Cooper, of Hoo Hills, near Market Bosworth, and Mr. Charles Clarke, of Lindley, near Hinckley, took the highest price—88s. per cwt. Other dairies made 88s. and 84s., and several 70s. to 80s. For a long time the price ranged from 60s. to 65s., but now it pretty nearly touches 80s. for "all useful things." Skim milk cheese has been made in the Stilton dairies, but the American Factory cheeses, which are 90lbs. weight, and very similar to Cheddar, have nearly beaten it out of the market and interfered seriously with new milk cheese up to 75 shillings. About four of these cheeses go to the hundred-weight, which is 112lbs. in Warwickshire and 120lbs. in Derbyshire and Leicestershire. The cheese of the year is divided into two weighs. The first, which is pitched at Leicester on or about May 12th, seldom exceeds 500 tons, and includes the produce of the dairies from about August to the end of the season. The second weigh, which is superior from the fact that it has no fodder cheese in it, and represents the make from May morning up to August 27th, comes out to the amount of 1,000 to 1,200 tons (not reckoning in Stilton) at the Leicester October fair. Of course, the Birmingham and Leicester factors have been busy with their tasters long before them; and hence a great weight of cheese is never pitched in the fair at all. Several Lincolnshire and Norfolk dealers come to Leicester, and so do some of the Scottish ones, and London and the Continent have their full share. The tastes of the different counties vary on one great point. For instance, Yorkshire, Derbyshire, and Scotland like their cheese coloured; and Norfolk, Essex, and Suffolk prefer it plain.

Mr. Nuttall, of South Croxton, generally pitches about 12 tons, two-thirds of it in October and a third in May. His farm, which his late father entered upon in 1825, contains 300 acres in grass and 130 under plough. It is rather cold land and not a kindly soil for roots, and 20 tons per acre of yellow globe mangold is a satisfactory crop. About ten acres of it are grown, eight are kept for swedes and common turnips, and two for drumhead cabbage. These crops have no stint of good farmyard manure, in addition to top-dressing and phosphates, as the cattle eat all the corn, except wheat, grown on the farm; and 60 tons of cake as well. The pastures are simply sweetened with a little bone-dust.

Brewers' grains are used for the cows, and of bean-

meal there is no stint during cheese-time. Mr. Nuttall brings up a few queys calves each year, and buys in his cows or heifers so as to calve down on the grass. They are kept out night and day till Christmas, and then tied up entirely until the middle of April. From Old May-day till the end of June the eighty cows will be making seven full-milk cheeses, or 240lbs. weight per day. The cheeses are made up morning and evening, and the family likeness is always maintained of five inches high by seventeen across. The principal features of the dairy are the five stone, and the two lever presses, and the cheese must be in the press, and in salt for a full week. All the cream bowls are of Penrhyn slate, which is considered much sweeter for the purpose than lead. About one pound of whey butter per week is made from each cow, and 240 gallons of whey are sometimes sent daily through the pipes to a large underground cistern into the yard. It is pumped out of this for the pigs, of which about seventy are fed off each year. Mr. Nuttall's practice is to buy them, at an average, for £3, or about 10s. a-score, and to keep them under high pork pressure for four or five months.

The inhabitants of Stilton refer to Pope, and "A Tour through the whole Island of Great Britain, written by a gentleman," as far back as 1725, to prove that they were the earliest makers of our "English Parmesan." In Leicestershire the honour of being its fountress was awarded by some to a Mrs. Pick, of Withcote, and by others to a Mrs. Orton, of Great Dalby. The supporters of the first good dame, who died, we believe, about twenty-four years since, *etat* ninety-six, maintain that it was always known by the name of "Withcote cheese," and that the Huntingdonshire town had never any part or lot in the matter, and merely substituted a better cheese for their own "old original," and bestowed on it their name. Be it Stilton or be it Withcote, the two Dalbys, Skeffington, Tugby, Tilton, Kilby Thorpe, Twyford, and Asfordby are among its great Leicestershire strongholds. It requires so much "fadding," that the largest dairies do not care to make it. Sweet-milk cheese makers are wont to compare the process to having a troop of infants at nurse. There are seldom more than two dozen cows in a Stilton dairy; but Mrs. Emalie, of Asfordby, has nearly forty on ninety acres round home, and at Grimston, and turns out about sixty dozen cheeses of about 15lbs. each in a season. Once upon a time, from 10lbs. to 12lbs. were the average weights, but they have gradually gone up. The factors generally begin to inspect the dairies about the middle of August, and take so many dozen "at Time's price," which is guided by Loughborough fair.

Stilton, like new-milk cheese, requires an immense deal of management on rich land, which is apt to make it "slape-coated," and to generate mites. Poor land does not give half the trouble, and entails far less draining in cloths. It is made with the full morning's milk, half the overnight's milk (of which a portion is sometimes heated), and all the overnight's cream, but it doesn't always get treated so well. The whey makes good cream, and the salt is taken off it by filling up the cream bowl with hot water. Many makers like to keep their rennet in salt, as it is keener, and binds the curds better. The curd so formed is pressed in strainers for the day to make it firm, and then placed in hoops and bound round with cloths, till it becomes dry and coated. The cloths are changed twice-a-day, so as to let the coat form naturally, and the outside is also smoothed with a knife. If it is warm weather, the cheeses will acquire that nice melon-like rind in four or five days. Some of them will lose 6lbs. in drying. For choice they should be kept eight months, though the green mould will appear in three or four. With a warm summer, they ripen much faster, but great attention to atmosphere is required, as the flies will strike them as they

do meat, and the mites must be kept away by assiduous brushing. There is in truth nothing that requires more unwearied attention than a cheese dairy, as new-milk cheese failures are almost uneatable, and some Stiltons are painful to look at, sinking down on one side, as if the whole fabric had given way from below, or degenerating into rusty cannon balls, which have been half flattened against a fort. Anyone who has been through a large cheese warehouse, and seen the taster put into their "frightful examples," can never forget it.

The first "draw" or "weigh" of Stilton cheese in August is generally for shipping, and India is a capital customer. For fresh samples it is difficult to make more than 9d.; but cheese which has been kept for seven months will reach 11d. or a 1s. Really good mellow Stilton should have a smooth, velvety feel in the hand, and a creamy and yet rather sharp taste in the mouth, as the tendency of creaminess is to make them unduly sweet. After all, the late Mr. John Moore of the Old Club at Melton Mowbray described the real article best, when he requested the house steward to procure him "a ripe, red, rusty, and rotten one."

Eddish or aftermath cheese is a sort of aristocratic Stilton, and the undisputed honour of its invention seems to rest with Mrs. Heeley, of Little Dalby. The makers generally begin about the first week of September; but not more than a ton of it is made in the whole county, and that principally round the Dalbys. It is circular in shape, and seldom above 8 or 10 lbs., of a light creamy character, and rather more expensive than common Stilton. When well made it is tasty, but sadly hazardous and breakable in the making, and apt to waste very much as well.

As regards "improved pigs," records point to Mr. Honeybourne of Dishley, whose breed earned the curious recommendation from one writer of "appearing to be crossed with the wild boar." Mr. Buckley of Normanton and Mr. Astley of Odstone were also among the earliest Leicestershire pig-fanciers. Chinese and Berkshire were the Odstone cross; and it was also the practice of the late Mr. Beale of Frolesworth, who was quite a Midland Counties Wainman in his day, to cross the short and thick Chinese, or "Tunkey," as it was called, with the Large Leicester or the Middle-sized Yorkshire, which produced a first-class pig of great weight. Mr. Brendon Everard feeds pigs on a still more extensive scale than Mr. Nuttall; and the whites are kept more or less at every farm-house, which seldom lacks a home-made pork-pie in the season. The pig-jobbers buy porkers of six weeks and upwards, about Hitchin and Bedford, &c., and take them round to the farmers, as there is no pitched market worth speaking of at Leicester. They were once kept to fifteen or eighteen months; but the farmers prefer to realize quicker, and they suit the curers better. Derby is a great curers' market for fat hogs, which are fed by the Derbyshire dairy-farmers, and are rather sandy-coloured, like the Staffordshire sort. Northamptonshire pigs are generally black-and-sandy; and large supplies are drawn by the curers in Leicester (which is gradually becoming a great provision-warehouse for the midlands) from Mr. Wallace of Kettering, Mr. George of Bythorn, and other extensive breeders.

In a good milk-district the pigs get whey and skim-milk, when the cheesemaking is over, along with light corn, barley-meal, beans, and plenty of potatoes. A great pork-pie maker was wont to say that, if he wanted a very special pie, he should feed the pig on baked potatoes. About five hundred pigs are slaughtered weekly in Leicester during the height of the curing season; and a large portion of the legs, loins, and other loose meat is used for pies, both by the Leicester and Melton Mowbray makers. One great ham and bacon firm in Leicester

occasionally kills more than 200 pigs a week on the American principle, which consists in hauling them up by pulleys head downwards, cutting their throats, and then sliding the carcasses, by means of an iron rod, along the ceiling, through the scalding-tub, and other processes, until they are finally cut down in the curing-house. In Leicester the curing does not cease in April; but after that date the ham is split, and is cured as part of the fitch.

Those who may have been leaving Melton Mowbray by the early train cannot have failed to notice several pork-pie hampers at the station. Mr. Adcock began this trade here about forty years ago, and it is still confined to five or six, and rather fewer in Leicester, at least of any importance. November to April is the season, corresponding, in fact, to the "Cumberland ham and bacon-curing term," and some of the makers fill up the intervening months with veal-and-ham pies. A few of them do not content themselves during the season merely with buying legs and loins, but kill pigs for themselves and cure the fitches. The pies are made of all sizes from 1lb. to 20lbs. The smallest ones are principally consumed at railway stations, and the 2lb. and 3lb. pies are destined for higher class customers, and go to the Universities and all over the kingdom, for breakfast and luncheon. Some of the makers turn out from 400 to 500 pies a week, and calculate the rate of baking in a fast oven at one hour for a 1lb. pie, and  $2\frac{1}{2}$  hours for a 3lb. The late Mr. Colin, who acted for eleven years as cook to Sir Harry Goodricke, was the leading maker for many years.

The sheep which bear the county name and had Bakewell for their "inventor" alone remain for notice. Mr. Creswell's father, who died at a patriarchal age two years since, was almost the only man left who remembered him (with his straws or bag of figured marbles on letting days) by sight. Of the Bakewell Ram Club, Mr. Brendon, of Rotharby, was the latest survivor. Mr. Bakewell was buried in the church at Dishley, which has been dismantled for more than one-and-twenty years, and it is no light task to discover his grave in the chancel, where the pigeons roost and the birds make their nests with impunity. His flock descended to his nephew, Mr. Honeybourne, and was gradually dispersed among the Messrs. Stabbins, Stone, Barford, Paget, Baker of Elemore, and Philip Skipworth the elder. Mr. Bosworth is now the tenant of Dishley, and nearly everything has suffered change since then. The Stabbins flock passed over to the Burgesses of Holmepierrepoint and Cotgrave, and was sold off when they died or retired, and much of the blood came into Mr. Sanday's and Mr. Torr's hands. Mr. Buckley's descendant has parted with his flock, and the Stones of Quorn and Barrow, to whom the late Sir Tatton Sykes paid his annual visit amongst others, are known as "shepherd kings" no longer.

The late Mr. Creswell and his father bred from Stone and Stabbins, and Mr. Creswell still keeps a small flock on his paternal acres at Ravenstone, and has won firsts at the Royal with rams at Newcastle, Plymouth, and Bury, besides meeting Mr. Borton successfully at the Yorkshire

show. His Plymouth ram was Black-knee, purchased for sixty-two guineas at Mr. Sanday's sale. Messrs. Spencer, of Snarestone and Whiptoft, also breed pure Leicesters, and for three years past Lord Berners has taken the Smithfield gold medal with his wethers, which have a strong dash of the Sledmere blood.

It is not a county of large flocks; but of late years, more especially on the Market Harborough and Loughborough side, farmers have broken up their land and kept more sheep. The blue-headed Leicester is quite the favourite. The great Leicester sheep fair is on October 10th, and is continued for hoggs for several subsequent Saturdays. The rams have generally been purchased before the fair, and Lincolns, Shrops, and Half-breds have "their claim allowed." The Duke of Rutland's tenants use the Lincoln pretty deeply; but the Shrop is the great favourite, both from his sureness as a server, good constitution, and the value of "the black foot" in the butcher's eyes. Shropshire cull ewes are sometimes bought, and used, more especially round Melton Mowbray, for breeding fat lambs.

Until eight or nine years ago, when Lord Berners and some of his brother-agriculturists established one at Leicester, there was no wool fair in the county, and the wool staplers simply went round. That practice has by no means dropped through, and a great weight of wool is never pitched in the Bell Yard; but still the fair sets the market-price, and the farmer is not left, as he once was, to draw his bow very much at a venture. The fair has become a very important one; and the telegram of its proceedings this year made its mark on the Edinburgh auction sales, which were going on the same day. The following are the regulations of the fair, which is held on the last Wednesday in June:

"No wool will be received later than nine o'clock on the morning of the fair.

"The stewards will be in attendance from ten o'clock until four the day previous, to receive the wool, and it is particularly requested that all parties will send their wool on that day; but it will be admitted from five o'clock to nine on the morning of the fair.

"A ticket must be sent with the wool, stating the quantity of each sort the lot contains.

"That the wool be weighed by the agents authorized by the stewards on its being brought into the yard.

"The sheets will be numbered, and the weight of each entered into a book; the buyers have the option of having it weighed over again if they think proper.

"That twopence per tod be paid by the seller on all wool sold at the fair.

"That the wool be weighed by the sheet, and half-a-pound per tod be allowed for draughts upon the wool, and no further reduction be recognized by the rules of the fair; and it is requested that no money or fee whatever be given to any of the attendants.

"Should any dispute arise between the buyer and seller, it shall be referred to the stewards, and the person they may appoint shall decide the matter in dispute, and his decision shall be binding upon both parties."

H. H. D.

## SMOKING ON THE FARM.

A correspondent wishes to caution farmers against the danger of fire from the practice of smoking either in the barn, the stack-yard, or the field, especially during the intense drought under which the country is now suffering. Two cases to which he refers, as having taken place under his own eye, are enough to appal any person liable to the

same circumstances. On miles of railway the stacks or fields of corn have been destroyed, and several hundred acres of a park by a supposed lucifer; while these are not by any means the only conflagrations that have occurred from the same cause during this summer. Several heaths and commons have thus been set on fire, and immense damage sustained thereby. Indeed, so universal has the

practice of smoking the short pipe become amongst the farm servants and labourers during the working hours—for which practice they can too often plead the example of their employers—that the wonder is, not that such results do take place, but that they are not of far more frequent occurrence. So reckless are those who acquire the habit, that they are perfectly indifferent as to where the lighted lucifer match, or the sparks from the pipe fall, as likely to be thrown upon combustible matter as not. From observation, we are of opinion that a very large proportion of the fires that take place in London arise from the same cause. Valuable business premises, with large stocks of goods, have been destroyed by a lighted match being thrown down an area grating in which was some straw. On the farm at the present time there is ten-fold danger of fire, from the excessively dry state both of the standing corn and the pasture land where there is any grass left, and farmers would be perfectly justified in establishing a rule prohibiting their men from smoking during working hours; a practice which, independent of the danger of fire, consumes no little of the time of labour. We know one instance in which an employer of several men, finding that they were in the habit of smoking while at work and that this led to a great waste of time, announced that any one of them found smoking when he ought to be at work would be dismissed. He only detected one man who transgressed the rule, and him he found drunk with a lighted pipe in his hand amongst some straw in the stable. It is a

question not yet settled whether the disastrous fire that took place a few days since in Kent, by which property to the amount of five or six thousand pounds, including two homesteads, were destroyed, was occasioned by a smoker or by sparks from a railway engine. In that case some fields of standing corn were destroyed; for the ripe straw this season is as combustible as tinder, and so also are the heather and furze on the commons, which have been fired in many parts of the country.

In relation to the same subject we would mention another most reprehensible practice of *street-smokers*, namely, throwing the *lighted lucifer-match* as well as the ends of an exhausted cigar on the pavement. We have, in our own experience, known of four cases in which ladies have been set on fire by such a reckless and dangerous habit; for which there is not the slightest excuse whatever. It would seem as if the very practice of smoking superinduced in some persons a degree of selfishness that renders them perfectly regardless of the welfare of others, whether male or female; otherwise they would see the impropriety of endangering the lives of the passers-by. So common is the habit of street-smoking become, and with it the danger, that it is positively unsafe for a lady in a muslin dress to walk about; for you may constantly see men fling down their lighted matches without any thought of, or care about the consequences. In such a season the farmer should use every precaution to prevent accidents from fire in the field and the homestead.

## GLOUCESTERSHIRE AGRICULTURAL SOCIETY.

### MEETING AT GLOUCESTER.

The Herefords were in tolerably good force at the society's annual show, reaching to 44 entries.

In the class for bulls above two years old, Mr. J. R. Paramore, of Dinedor Court, takes first prize with Dinedor; Mr. Duckham, of Baysham Court, second, with Reginald; while Mr. Taylor, of Showle Court, gets a first-class commendation with Triumph. In the class for bulls above one and under two years old, Mr. Paramore is again first with Chancellor, and Mr. Bradstock second; Mr. Prosser, of Broadway, being commended.

Amongst the bull calves, three in number, Mr. Paramore was first, and Mr. John Baldwin second.

The class for bull, cow, and offspring had three entries, with the first prize to Mr. Thos. Rogers, of Coxall; the bull being the Leicester prize winner, Battenhall; the cow, Gentle Anne. Mr. E. J. Morris, of Stanley Pontlarge, takes second prize with Memento.

In the class for breeding cows Mr. J. Baldwin is first with Venus 6th, a Monnaughty cow. This cow was shown at Bingley Hall last year, and was destined for the butcher; but Mr. Baldwin was persuaded to keep her, as she was then in calf, and having gone on very well she again appears in public.

Both prizes for heifers under three years old fell to Mr. Prosser, without competition; and there was virtually no competition in the class for heifer calves, in which the prize is taken by Mr. John Wignmore, who is also highly commended for three dairy cows.

The Shorthorns are, of course, in much greater force than the Herefords, numbering 106 entries; and some of the animals are excellent representatives of their breed. The chief prize-takers are Mr. Richard Stratton, Wall's End; Mr. Joseph Pulley, Lower Eaton, Hereford, who is second in the aged bull class, with Royal Buck, bred at Maindee, Newport; Viscount Sudeley, Earl of Radnor, Mr. Charles Hobbs (Maisey-hampton), Messrs. Garne and Son (Northleach), Mr. Geo. Garne (Chipping Norton), and the Rev. W. H. Beaver, Penraig Court, Ross. Viscount Sudeley takes the prize for the best Shorthorn bull in the yard, an aristocratic-looking white of rare quality; but many would prefer the bull which stands near him, belonging to Earl Radnor. For breeding cows, Mr. George Garne (Chipping Norton) took the first prize, as

well as the second for heifers. The Rev. W. H. Beaver takes second prize in the breeding cow and heifer calf classes; and in the latter class Mr. Stratton wins with a splendid animal; perhaps the best Shorthorn in the yard.

With sheep, 190 in number, the Cotswolds predominated, and there were many grand specimens shown by the most noted hill breeders; the aged prize ram of Mr. J. K. Tombs being an animal of grand scale and form. The Shropshires, very few in number, are good, the chief exhibitors being Mr. E. Holland, M.P., and Mr. Charles Randell, of Chadbury, each of whom takes prizes. In the other short-wool classes the Duke of Beaufort and the Earl of Radnor are prize-takers.

The pigs, numbering 80, were principally of the Berkshire breed.

The horse department was a large and attractive one, the entries reaching to 102. That good horse Ivanhoff, the property of Mr. E. Griffiths, of Marie Hill, near Cheltenham, was first in the class for thorough-bred stallions, and Mr. Henry Brown, of Monkton, Swindon, was second with a handsome dark bay by Artillery. In the class for entire cart-horses, Mr. Wynn, of Alcester, repeated his Birmingham and other victories with his grand grey A 1; and Mr. Wm. Allen, of Hart-pury, was second with a young roan. The classes for cart-horses, hunters, and hacks were good.

Three prizes were awarded for implements—to Nalder and Nalder (Limited), Challow, Wantage, for a thrashing machine; to Savory, High Orchard, Gloucester, for a corn mill; and to Waites, Northgate-street, Gloucester, for a chaff-cutter.

The judges for cattle were Mr. J. Knowles, of Wetherly, Yorkshire, and Mr. H. Higgins, of Woolaston Grange, Lydney. Sheep and Pigs: Mr. T. Porter, Baunton, and Mr. F. Burnett, Kingscote. Cart Horses: Mr. W. Richards, Dursley, and Mr. W. Curtis, Fernham, Faringdon. Hunters and Roadsters: Mr. J. R. Raymond-Barker, Fairford Park; Mr. A. Harrison, Edgbaston; and Mr. J. E. Bennett, Husbards Bosworth, Rugby. Implements: Captain de Winton, Wallsworth Hall; Mr. W. Glover, Warwick; and Mr. J. T. Harrison, Maids-hill, London.

The annual dinner of the society was held on Thursday in a large marquee on the ground; Mr. E. Holland, M.P. for Evesham, in the chair.

## THE HIGHLAND AND AGRICULTURAL SOCIETY'S SHOW AT ABERDEEN.

The forty-first annual show of the National Agricultural Society of Scotland was opened on July 29th, at Aberdeen, this being the fifth show which has been held by the Society in that City. The site of the showyard was The Links, about 14 acres of which had been boarded off, with stalls and shedding suitable for the display of stock and implements to the best advantage. There is a slight drawback in the undulating character of The Links, the surface not being so level as is desirable, but, notwithstanding this the Society may well be congratulated upon the site, and on the arrangements of the present exhibition. The most prominent feature of the cattle classes was the display of Polled Angus, which were shown in considerable numbers, and several very superior specimens were in competition. These included the famous Forth, now in the herd of Mr. Cruickshank, and Heir of Englishman, first here, and, as many would have it, the second-best at Leicester. The Galloways were also very good. It was also considered by several eminent judges that never at any previous exhibition of the society were there so many superior Short-horns brought together in competition. In the aged bulls the judges had apparently much difficulty in placing the animals. The class for two-year-old bulls was also good, but not equal to the aged class as regards uniformity and general excellence. Yearling bulls were a good class, but the cows were not very equal in point of merit. Owing to a misunderstanding between the directors of the Highland Society and the railway directors as to the returning free of charge of cattle in horse-boxes, some of the Ayrshires entered for exhibition were not sent forward; and, from the same cause, not content with simply not sending their horses to Aberdeen, a number of dissatisfied intending exhibitors arranged a show of Clydesdale horses and of Ayrshire cattle in Glasgow on the same day as the national show was being held at Aberdeen! The Society having offered the handsome prize of £100 for a thoroughbred horse to serve in the district, a number of well-bred animals were brought forward; the greater number of these, however, were better adapted for breeding carriage-horses and horses for the saddle. There was a fair show of roadsters and ponies, and as these were shown in action they attracted considerable attention. It was generally admitted that the Leicesters were the best show that has appeared north of the Tay. The Cheviots also were particularly good, but the competition was somewhat restricted; and there were very good specimens of the blackfaces. In the pig classes there was a very limited competition.

## JUDGES.

**Cattle.**—Short-horns: L. C. Crisp, Hawkhill, Alnwick; Joseph Culshaw, Towneley Park, Burnley; Andrew Mitchell, Alloa. Polled Angus: Robert Hector, Montrose; James Lealie, The Thorn, Blairgowrie; George Williamson, Shempston, Elgin. Polled Galloway: Thomas Gibbons, Burnfoot, Esk, Longtown, Cumberland; A. C. Pagan, Innergeldie, Comrie; James Shennan, Balig, Kirkcudbright. Highland: John McArthur, Acarrach, Inverary; Donald McIntyre, Tighnablaire, Comrie; Duncan Mitchell, Blairvockie, Luss. Ayrshire: H. D. B. Hyalop, Tower, Sanquhar.

**Horses.**—Draught Horses: John Dickson, Sanghton Mains, Edinburgh; Alexander Young, Kin Mains, Dunblane; John Young, Fulwood, Houston. Thorough-breds: George A. Gray, Millfield Hill, Wooler; Nicol Milne, Faldonside, Melrose.

**Sheep.**—Ayrshire: H. D. B. Hyalop, Tower, Sanquhar; Hugh Kirkwood, Killermont, Maryhill; John Waugh, of St. John's Kirk, Biggar. Fat Stock: Stewart Johnstone, Perth; D. Smith, Leyshade, Dundee. Leicester and other Long-woolled: William Purves, Linton Burnfoot, Kelso; John Wilson, Edington Mains, Chirnside. Cheviot: William Henderson, Langbeford, Wooler; John Scott, Drynock, Broadford, Skye; William Thompson, Ryle, Alnwick. Blackfaced: James Coubrrough, Blairtummoch, Campsie; George Howieson, Rannagulzion, Blairgowrie; Donald McIntyre, Tighnablaire, Comrie. South Down and other Shortwoolled: George

A. Gray, Millfield Hill, Wooler; G. A. Thompson, Farmine Hall, Carlisle.

**Pigs.**—James Deans, Dalkeith Park, Dalkeith; A. C. Pagan, Innergeldie, Comrie; James Shewan, Balig, Kirkcudbright.

## PRIZE LIST.

## CATTLE.

[NOTE.—All the third prizes received silver medals.]

## SHORTHORN.

First prize bulls at former shows.—Gold Medal, Amos Cruickshank, Sittytton, Aberdeen.

Bulls calved before 1st January, 1866.—First prize, £20, Geo. Barclay, of Keavil; second of £10, James Cochrane, Little Haddo; third, James White, Little Clinterty.

Bulls calved after 1st January, 1866.—First prize, £20, George Marr, Cairnbrogie; second of £10, David Ainalie, Costerton; third, John Copland, Mainhead.

Bulls calved after 1st January, 1867.—First prize, £10, George Robertson; second of £5, William S. Marr, Upper-mill; third, George Robertson.

Bull calves calved after 1st January, 1866.—First prize, £6, John Copland; second of £3, Alexander Bruce, Wealthiton. Cows of any age.—First prize, £15, George Shepherd, Shethin; second of £8, Amos Cruickshank; third, Charles Bruce.

Heifers calved after 1st January, 1866.—First prize, £10, David Ainalie; second of £5, the Duke of Buccleuch; third, Lord Kinnaird, K.T.

Heifers calved after 1st January, 1867.—First prize, £8, David Ainalie; second of £4, Lord Kinnaird, K.T.; third, David Ainalie.

Heifer calves calved after 1st January, 1868.—First prize, £6, Robert Scott, Manbeen; second of £3, William A. Mitchell, Auchnagathle; third, Henry A. Rannie, Mill of Boyndie.

Prize cows at former shows.—First prize, Gold Medal, the Duke of Richmond, K.G.

## POLLED ANGUS OR ABERDEEN.

First prize bulls at former shows.—Gold Medal, Alexander Paterson, Mulben.

Bulls calved before 1st January, 1866.—First prize, £20, and silver medal as breeder of best bull, Alexander Morison, of Beguie; second of £10, William James Taylor, Rothiemay House; third, Robert Walker, Portlethen.

Bulls calved after 1st January, 1866.—First prize, £20, William McCombie, of Easter Skene; second of £10, William McKnight, Boghead; third Robert Walker.

Bulls calved after 1st January, 1867.—First prize, £10, George Brown, Westertown; second of £5, the Earl of Dunmore; third, Robert Walker.

Bull calves calved after 1st January, 1868.—First prize, £6, William McCombie, Tillyfour; second of £3, David Bait Lyall Grant, of Kingsford, Alford; third, Robert Walker, Menthle-ton, Banff.

First prize cows at former shows.—Gold Medal, Trustees of the late J. H. E. Wemyss, Wemyss Castle, Kirkcaldy.

Cows of any age.—First prize, £15, Col. Charles Fraser; second of £8, and third, William McCombie, Tillyfour.

Heifers calved after 1st January, 1866.—First prize, £10, James Skinner, Drummin; second of £5, the Earl of Southesk; third, William McCombie, Tillyfour.

Heifers calved after 1st January, 1866.—First prize, £8, and second of £4, William McCombie, Tillyfour; third, the Earl of Dunmore.

Heifer calves calved after 1st January, 1868.—First prize, £6, second of £3, and third, Wm. McCombie, Tillyfour.

## POLLED GALLOWAY.

Bulls calved before 1st January, 1866.—First prize, £20, and silver medal as breeder of best bull, James Cunningham, Tarbroch; second of £10, James Graham, Parcelstown.

Bulls calved after 1st January, 1866.—First prize, £20, Jas.

Graham, Braidlee; second of £10, James Cunningham; third, John Cunningham, Whitecrair.

Bulls calved after 1st January, 1867.—First prize, £10, John Fisher, Knells, Carlisle; second of £5, John Cunningham.

Cows of any age.—First prize, £15, and second of £8, Jas. Cunningham.

Heifers calved after 1st January, 1868.—First prize, £10, James Cunningham; second of £5, the Duke of Buccleuch; third, James Cunningham.

Heifers calved after 1st January, 1867.—First prize, £8, and second of £4, James Graham, Parcelstown; third, the Duke of Buccleuch.

First prize cows at former shows.—Gold Medal, James Graham, Parcelstown.

#### HIGHLAND.

Bulls calved before 1st January, 1865.—First prize, £20, and silver medal as breeder of the best bull, John Malcolm, of Poltalloch; second of £10, the Duke of Athole; third, Alex. Fraser, Fallow.

Bulls calved after 1st January, 1865.—First prize, £20, the Duke of Athole; second of £10, Donald M'Laren, Corrychone; third, J. Gordon, Manar.

Bulls calved after 1st January, 1866.—First prize, £10, and second of £5, John Stewart, Duntulm; third, the Hon. Lady Menzies.

First prize bulls at former shows.—Gold Medal, Robt. Peter, Ular.

Cows of any age.—First prize, £15, John Malcolm; second of £8, John Stewart, Duntulm; third, the Duke of Athole.

Heifers calved after 1st January, 1865.—First prize, £10, Robert Peter; second of £5, John Malcolm; third, Robert Peter.

Heifers calved after 1st January, 1866.—First prize £8, the Duke of Athole; second of £4, and third, John Malcolm.

First prize cows at former shows.—Gold Medal, the Duke of Athole, K.T.

#### AYRSHIRE.

Bulls calved before 1st January, 1866.—First prize, £10, and silver medal as breeder of the best bull, Wm. Buchanan, Coxithill; second of £5, John Stewart, Burnside Cottage.

Bulls calved after 1st January, 1866.—First prize, £20, Robert Wilson, Forehouse; second of £10, John Stewart.

Cows in milk of any age.—First prize, £15, Robt. Wilson; second of £8, John Semple, Dunbarrow; third, John Stewart.

Cows in-calf of any age.—First prize, £15, A. Morton, Bickerton Hall; second of £8, John Stewart; 3 Robert Wilson.

Heifers calved after 1st January, 1866.—First prize, £10, Robert Wilson; second of £5, and third, John Stewart.

First prize cows at former shows.—Gold Medal, the Duches Dowager of Athole.

#### FAT STOCK.

Polled oxen calved after 1st January, 1865.—First prize, William M'Combie, Tillyfour; second, James Stephen, Conglass; third, James Skinner, Drumin.

Polled oxen calved after 1st January, 1866.—First prize, Wm. M'Combie, Easter Skene; second, Wm. M'Combie, Tillyfour; third, Robert Bruce, Kinloss.

Oxen of any pure or cross breed calved after 1st January, 1865.—First prize, Thomas Ross, Hill Head; second, Richard H. Harris, Earnhill; third, John Frost, Delab.

Oxen of any pure cross breed calved after 1st January, 1866.—First prize, Wishart and Wisely, 92, Gallowgate, Aberdeen; second, William M'Combie, Tillyfour; third, Robert Moir.

Highland oxen calved after 1st January, 1864.—First prize, J. and W. Martin, Aberdeen; second, George and J. G. Smith, Minmore, Ballindalloch; third, the Duke of Sutherland.

Highland oxen calved after 1st January, 1865.—First prize, George and J. G. Smith; second, Alexander Mitchell, Newburgh; third, Thomas Knowles, Aberdeen.

Cross heifers calved after 1st January, 1865.—First prize, Robert Bruce, Forres; second, James Reid, Graystone; third, James Skinner, Auchmull.

Cross heifers calved after 1st January, 1866.—First prize, Alexander Cowie, Cromleybank; second, Harry L. L. Morrison, Guise; third, J. and W. Martin.

#### EXTRA CATTLE.

Silver medals have been awarded to James Stephen and Walter Scott.

Silver medals have been awarded to Alexander Morrison, Bognie; Robert Walker; J. and W. Martin; and Harry L. L. Morrison, Guise.

#### HORSES.

##### FOR AGRICULTURAL PURPOSES.

Stallions foaled before 1st January, 1865.—First prize, £30, James Hall, Aberdeen; second of £15, Murdo Bethune; third, John Thomson.

Entire colts foaled after 1st January, 1865.—First prize, £20, Samuel Clark, Manawrae; second of £10, John Macdonald, Duntocher; third, John Walker, Isaacstown.

Entire colts foaled after 1st January, 1866.—First prize, £15, The Earl of Strathmore; second of £8, Peter Beattie, Dunnydeer; third, Wm. Wilson, Balquharn.

Entire colts foaled after 1st January, 1867.—First prize, £10, Jos. Tait, Portsoy; second of £5, Alex. Milne, Corse of Kinnoir; third, The Earl of Strathmore.

Mares (with foal at foot) foaled before 1st January, 1865.—First prize, £20, Alexander Sim, Fawella, Keithhall; second of £10, Murdo Bethune, Dreim of Highfield, Beaul; third, Adam Gray, Harestone.

Mares (in-foal) foaled before 1st January, 1865.—First prize, £15, and second of £8, Alex. Milne; third, Andrew F. Williamson, Caskieben Mains.

Fillies foaled after 1st January, 1865.—First prize, £10, John Kerr, Mid-Calder; second of £5, James Murray, Fauchfauld; third, John Taylor, Coldstream.

Fillies foaled after 1st January, 1866.—First prize £8, James Freeland, Broadgate, Strathblane; second of £4, The Duchess Dowager of Athole; third, Patrick Davidson, Inchmarlo.

Fillies foaled after 1st January, 1867.—First prize, £6, James Moir, Wardhouse; second of £3, Thomas Milne, Insch; third, William Riddell, Hillhead.

EXTRA SECTION.—Thorough-bred stallions, to serve in the district.—Prize of £100, Robert Paterson, Birthwood, Biggar.

EXTRA HORSES.—Roadsters.—Silver medals were awarded to Alex. Brown, Pitcairle; James Hay, jun., Little Ythais; and James Lamsden, Braco.

#### SHEEP.

##### LEICESTER.

Tups not four-shear.—First prize, £10, George Thomson, Pitmedden; second of £5, Lawrence Drew; third, John Hunter.

Dinmont or shearing tups.—First prize, £10, David Ainslie; second of £5, Adam Smith; third, The Earl of Southesk.

Ewes not above four-shear.—First prize, £8, Lawrence Drew; second of £4, David Ainslie; third, George Simson.

Shearling ewes or gimmers.—First prize, £8, George Simson; second of £4, David Ainslie; third, George Torrance.

##### CHEVIOT.

Tups not above four-shear.—First prize, £10, Thomas Elliot; second of £5, James Brydon, Kinnelhead; third, Thomas Elliot.

Dinmont or shearing tups.—First prize, £10, John Archibald, Glengelt; second of £5, Thomas Elliot; third, John Archibald.

Ewes not above four-shear.—First prize, £8, John Archibald; second of £4, Thos. Elliot; third, John M'Gregor, Bellridding.

Best pen of Lambs.—Thomas Elliot.  
Shearling ewes or gimmers.—First prize, £8, James Brydon; second of £4, Thomas Elliot; third, John Archibald.

##### BLACKFACED.

Tups not above four-shear.—First prize, £10, John Archibald, Overshiels; second of £5, Thomas Aitken, Listonshiels; third, John Archibald.

Dinmont or shearing tups.—First prize, £10, second of £5, and third, John Archibald.

Ewes not above four shear.—First prize, £8, John Archibald; second of £4, Allan C. Pagan, Comrie; third, the Hon. Lady Menzies.

Best pen of lambs.—Silver medal, John Archibald.  
Shearling ewes or gimmers.—First prize, £8, John Malcolm; second of £4, John Inch, Mitchellhill; third, John Archibald.

## SOUTHDOWN.

Tups not above four-shear.—First prize, £10, John Gordon, Parkhill; second of £5, Robert Scot Skirving; third, John Garland, Cairnton.

Ewes not above four-shear, or gimmers.—First prize, £8, Robert Scot Skirving; second of £4, Alexander Kinloch jun., Gilmerton; third, Sir W. G. Gordon Cumming.

## LONG-WOOLLED OTHER THAN LEICESTER.

Tups not above four-shear.—First prize, £10, John Gibson, Woolmet; second of £5, and third, Walter Reid.

Ewes not above four-shear, or gimmers.—First prize, £8, Walter Reid; second of £4, John Gibson; third, Walter Reid.

## SHORT-WOOLLED OTHER THAN SOUTHDOWN.

Tups not above four-shear.—First prize, £10, John Gibson; second of £5, and third, The Earl of Strathmore.

Ewes not above four-shear, or gimmers.—First prize, £8, The Earl of Strathmore; second of £4, John Gibson; third, James Walker, St. Andrews.

## EXTRA SHEEP.

Cheviot widders not above three-shear.—First prize, £6, Thomas Biggar; second of £3, Richard Heath Harris; third, James McGill, Rotchell.

Blackfaced widders not above four-shear.—First prize, £6, Wm. McCombie, Tillyfour; second of £3, James Stewart, Aberdeen; third, Andrew Wilson, Alford.

Cross-bred widders not above three-shear.—First prize, £6, James Stewart; second of £3, John Hunter; third, Richard Harris.

## SWINE.

Boars, large breed.—First prize, £8, Thomas D. Findlay, Easterhill; second of £4, John Laing; third, James Dyce Nicol, M.P.

Boars, small breed.—First prize, £8, R. E. Duckering and Sons; second of £4, Thomas D. Findlay.

Sows, large breed.—First prize, £6, Thomas D. Findlay; second of £3, James Skinner; third, R. E. Duckering and Sons.

Sows, small breed.—First prize, £6, Thomas D. Findlay; second of £3, R. E. Duckering and Sons; third, James Gordon, Manar.

Pens of three pigs not exceeding eight months old, large breed.—First prize, £4, Thomas D. Findlay; second, R. E. Duckering and Sons, Northorpe; third, William Benton, Alford.

Pens of three pigs not exceeding eight months old, small breed.—First prize, £4, Thomas D. Findlay, Glasgow; second of £2, Robert Philp, Bridge of Allan; third, James Gordon.

At the banquet, which took place in the Royal Hotel on Tuesday afternoon, His Grace the Duke of Buccleuch presided, and Lord Dalhousie acted as croupier.

The CHAIRMAN said the show had been one of the most successful the society had had. He was informed that of polled cattle especially the exhibition was one of the finest which had ever been brought together in Scotland. In only two classes, Ayrshire cattle and work horses, was there a deficiency.

LORD DALHOUSIE said: I have been of opinion that the chair of the Highland Society is the "blue ribbon" of agriculture in Scotland, and I think that the "blue ribbon" ought to be dispensed to those who have a knowledge of, and take an interest in agriculture, rather than be confined simply to rank. My Lord Duke, I say this in your presence, rather than in the presence of any other man who has been president of the Highland Society, because if ever a man was entitled, apart from rank, to wear the blue ribbon of the society, it was yourself. There are others holding the same position in society which you do, who have filled the chair of the Highland Society, without having the same claims that you have to that honour; and I think it is somewhat of a reflection upon the Highland Society to say that noblemen, estimable in every respect in their private characters, are preferred, as president of the Highland Society, to such men as the Marquis of Tweeddale, a man who has distinguished himself through a long life not only as a great patron of agriculture, but as one of the most practical of agriculturists, both in tilling the soil and rearing cattle, that we have ever had amongst us. I should like, before the days of that noble lord are worn out, to see him wearing that blue ribbon to which he has such high and acknowledged title.

## SOUTH LINCOLNSHIRE AGRICULTURAL SOCIETY.

## MEETING AT GRANTHAM.

The South Lincolnshire Agricultural Society held its inaugural meeting in the extensive grounds of Mr. H. Brett, at Spittlegate, Grantham, on Friday, July 24, when prizes to the amount of about £660 were competed for. In every respect the meeting was a success. The weather was fine and genial; the entries large, numbering 360 horses, short-horned cattle, sheep, and pigs, 203 poultry, and 42 stands of implements; the number of visitors large, and the arrangements complete and effective.

The horses formed the most numerous class of anything on the ground, the entries numbering 173. The highest prize of £50 for the best four-year-old mare or gelding, in riding order, calculated to make a hunter, was awarded to Brigadier, belonging to Mr. J. B. Booth, of Killerby, that was sold on the ground for the large sum of 400 guineas. Mr. J. W. King, of Ashby Hall, carried off the prize of £20 for the best thorough-bred stallion with Ratacatcher.

Amongst the Shorthorns, the first prize of £20 for bulls and the cup were carried off by Commander-in-Chief, belonging to Mr. T. C. Booth, Warlaby. It was also a somewhat remarkable animal, too, that took the highest prize for the bull exceeding one and not exceeding two years old. This was Lady Pigot's Rosolio, which has been seven times exhibited, and has been successful on every occasion, taking first prizes four times, and second three times. The bull-calf which took the prize of £10 belonging to Mr. G. S. Poljambe, of Osberton Hall, has not been shown before. It was got by the same bull as a couple of calves which took first and second honours at the Royal Show, out of the same cow as Rosa Windsor and The Archduke.

Perhaps of all the classes of animals the sheep presented the most formidable difficulties for the judges, because of their being uniformly good; while of pigs there was only a small show, but the deficiency was amply compensated for by the quality of the animals exhibited.

The show of implements was an imposing one, the whole county being well represented, but, as might naturally have been expected, with Grantham taking the lead in the number of entries, and also doing great things in the way of taking prizes.

## LIST OF PRIZES.

## HORSES.

JUDGES: Of Riding-horses, Lord Keateven, Mr. H. Chaplin, and Mr. C. Nainby; of Cart-horses, Mr. J. H. Wood, Mr. Smeeton, and Mr. T. Colton.

Thoroughbred stallion, for getting hunters (to serve half-bred mares at not more than £5 5s.)—First prize of £20, J. W. King, Ashby Hall; second of £10, Thomas Garne, Willoughby Heath Farm.

Stallion for getting draught horses.—First prize of £15, W. Welcher, Upwell; second of £5, J. Bell, Sturton Retford.

Stallion for getting roadsters.—Prize of £8, Captain F. Barlow, Castle Donington.

Mare for breeding hunters.—First prize of £10, John Byron, Kirby Green; second of £4, R. Hornsby, Grantham.

Mare for breeding draught horses.—First prize of £8, William Tennant, Barlow, Selby; second of £4, B. Padgett, Muston.

Weight-carrying hunting gelding or filly, the property of a

farmer or tradesman.—First prize of £15, W. Stephenson, Bushy Hill, Newbold; second of £5, W. Dudding, Howell.

Horse or mare which can jump the best to the satisfaction of the Judges.—Prize of £10, J. Greenham, Blankney Fen.

Four-year-old mare or gelding.—First prize of £50, J. B. Booth, Killerby Hall, Catterick (given by Mr. H. Chaplin); second of £10, E. Paddison, Ingleby (given by the Association).

Hunting gelding or filly, three years old.—First prize of £10, W. R. Brockton, Farndon; second of £4, R. Hornsby, Grantham.

Hunting gelding or filly, two years old.—Prize of £10, J. W. Gardom, Butterton Park, near Newcastle.

Foal by a thoroughbred horse.—Prize of £3, R. Johnson, Westborough.

Cart filly, two years old.—Prize of £4, John Brewster, Denton Lodge.

Cart filly, one year old.—Prize of £3, C. Lister, Coleby Lodge.

Cart colt foal.—Prize of £5, W. B. Brockton, Farndon.

Cart filly foal.—Prize of £3, T. Sills, Billingborough.

Pair of cart-horses (mares or geldings), not more than seven years old.—Prize of £10, J. C. Woolhouse, Wellingore.

Mare or gelding, for harness purposes, under seven years old.—First prize of £4, J. Hornsby, Grantham; second of £2, J. W. Palethorpe, Harlaxton.

Weight-carrying cob, not exceeding eight years old.—Prize of £5, J. Hornsby, Grantham.

Pony, not more than thirteen hands in height.—First prize of £4, W. Bedford, Grantham; second of £2, A. Gny, Eaton.

#### SHORT-HORNED CATTLE.

JUDGES: Mr. W. Sandy, Mr. Torr, and Mr. W. Bartholomew.

Bull, exceeding two years old.—First prize of £20, T. C. Booth, Warlaby; second of £10, J. Lynn, Stroxtun.

Bull, exceeding one, and not exceeding two years old.—First prize of £10, Lady Pigot, Branches Park; second of £5, G. S. Foljambe, Osberton Hall.

Bull calf, not exceeding one year old.—First prize of £10, G. S. Foljambe, Osberton Hall; second of £5, J. Lynn, Stroxtun.

Bull, exceeding one and not exceeding four years old.—First prize of £15, John Lynn, Stroxtun; second of £5, F. W. Brook, Brauncewell.

Cow, in-calf.—First prize of £10, T. C. Booth, Warlaby; second of £5, James How, Broughton.

Heifer, in-calf.—First prize of £10, Lady Pigot, Branches Park; second of £5, J. Lynn, Stroxtun.

Heifer calf, not exceeding one year old.—Prize of £8, Thos. C. Mayfield, Hagnaby.

Cow or heifer in any of the classes, exhibited by a tenant-farmer residing in South Lincolnshire.—Prize of £10, John Lynn, Stroxtun.

#### COTTAGERS' PREMIUMS.

The best milch cow.—First prize of £3, Joseph Ripley, Normanton; second of £1 10s., John Nix, Ropaley; third of 10s., John Hack, Little Ponton.

Heifer, under two-and-a-half years old.—Prize £2, W. Bullimore, Belton.

#### EXTRA STOCK.

Pair of bullocks.—Prize of £5, Wm. T. Lamb, Welbourne.

A CHALLENGE CUP, VALUE TWENTY GUINEAS.

Bull of any age.—T. C. Booth, of Warlaby.

LONG-WOOL SHEEP (not being Leicesters).

JUDGES: Mr. L. Borman, Mr. W. Chatterton, and Mr. J. Painter.

Ram of any age.—Prize of £20, John H. Casswell, Laughton.

Shearling ram.—First prize of £10 and second of £5, Chas. Clarke, Scopwick.

Two-shear ram.—First prize of £10 and second of £5, John H. Casswell, Laughton.

Pen of five gimmers.—First prize of £10, C. Clarke, Ashby-de-la-Launde; second of £5, Charles Lister, Coleby Lodge.

Pen of five ewes.—First prize of £10, C. Clarke, Ashby-de-la-Launde; second of £5, F. Sardeson, Cranwell.

#### LEICESTER SHEEP.

Ram, of any age.—Prize £10, John Lynn, Stroxtun.

Pen of five ewes or gimmers.—Prize of £5, John Lynn, Stroxtun.

#### EXTRA STOCK.

Pen of five shearling wethers.—Prize of £5, T. R. Casswell, Quadring.

#### PIGS.

JUDGES: Mr. L. Borman, Mr. W. Chatterton, and Mr. J. Painter.

Boar of the large breed.—First prize of £5, R. E. Duckering and Son, Northorpe; second of £2, Thomas Cant, Barkston.

Breeding or suckling sow, of the large breed.—First prize of £4 and second of £2, R. E. Duckering and Son.

Boar of the small breed, not exceeding eighteen months old.—First prize of £5, R. E. Duckering and Son; second of £2, W. Bartholomew, Waddington Heath.

Breeding or suckling sow of the small breed.—First prize of £4, G. P. Watson, Londonorpe; second of £2, R. E. Duckering and Son, Northorpe.

Boar of the Berkshire breed, not exceeding eighteen months.—First prize of £4, W. Dudding, Howell.

Boar of any breed or age.—First prize of £5, R. E. Duckering and Son.

Three breeding pigs of one litter, exceeding three and not exceeding six months old.—First prize of £5, R. E. Duckering and Son.

### DRIFFIELD AGRICULTURAL SOCIETY.

Driffield, renowned as it is for its show of horses, more especially its hunting classes, has not kept pace with the times as to the management and conduct of the show-yard, for a more primitive exhibition in that respect we have seldom come across. With the animals left without the slightest protection from sunshine or rain, the public, although supplied with a catalogue, if not possessed of the determination, sagacity, and stoutness of a foxhound to run each horse to his lair, and read the parcel-like label with which he was ticketed, was left totally in the dark as to what he was or to whom he belonged. Beyond this, for some cause unknown to anyone but the layer-out of the ground, a fair-sized ring, that would have allowed the horses to get into something like a stride, was divided in half by a rail, either to bring it down to the confined dimensions of the Halls

of Islington or Birmingham, or to make use of an extra stock of labour, timber, and ingenuity. Then at mid-day the judging was stopped an hour or two for luncheon, hear, hear, Bravo! and so forth; the consequence being that the visitors became wearied out, and took their departure long before the roadster and coaching stallions were judged; while the string of hunters sent for exhibition, though not for competition, by Mr. President Hall, stood all the day clothed in a corner of the field, and were never paraded at all! Mismanagement in these parts is more to be wondered at, as the Society has such a model to go by in its big brother—the Yorkshire Agricultural Society. The show of horses was good, but the great attraction was the hunting-classes, the first to come before the judges being the hunting brood-mares. Of these, four in number, the first was a

neat little mare, by Sleight of Hand, bred by the late Sir Tatton Sykes, whose well-known stud-groom Snarry was in the flesh, leading a hunter of the present baronet's about the ground. The second mare, Annie by Robinson, showed some hunting character, with well-formed limbs; while Mr. Holtby's The Nun was remarkable for her large frame and faulty forelegs; and the best two-year-old hunting gelding, or at least the picked one, was anything but perfect in his tobacco-pipe-like pins. Mr. Danby, of Beverley, had a good-looking youngster, by Defender, quite a model if in a coaching class; and Sir George Cholmley a couple, by Angelus, the gelding being remarkable for his size and coarseness, while the filly was passable. Amongst the yearlings Sir George was first, with a leggy, flat-sided, soft-looking one, by the same horse, beating, among others, anything but a bad-made filly, by Piccador, of Mr. Hudson's, of Beverley. For the silver cup, given by the President, a dozen, out of an entry of seventeen, came before the judges, making a fair-looking class, the mug eventually going to Mr. Booth's Brigadier, the first four-year-old at Leicester, and who has since been gathering honours at Louth and Grantham, beating Honesty, a nicely-put-together stylish horse, by the Cardinal, of Mr. Stephenson's, of Brough; Julius by Orpheus, another overgrown one, with anything but symmetrical looks, of Sir George Cholmley's, although he took first four-year-old honours at Bridlington, on the Tuesday—a Society, in its thirty-third year, that for management is, if anything, rather behind Driffield. Mr. Barkworth's Hidalgo by Cavendish, a shortish, powerful horse, with his head set on throaty, went very oily and well; Mr. Harrison exhibited a nice-looking bay by Napoleon, and Mr. Holiday one by Codrington. The silver cup, for three-year-old hunting geldings or fillies, went to Syringer by Orest, a fine-grown bay gelding, of Mr. Lambert's, of Welton, a well-known *slashing* rider in Yorkshire; the commended being a chesnut filly of Mr. Danby, of Louth, and rather back at her knee, while a deep, short-legged black mare by Walkington, dam by Orestes, with length, breed, and good ends, just recovering from the strangles, was well worthy of notice, if not the pick of the basket. The All England silver cup for mares or geldings of any age, with an entry of forty-one in the catalogue, brought twenty-five into the ring, the principal absentees being the General and Master of Arts. The former, we think, might have taken the cup; while the latter, that Trojan horse and prize glutton, we saw passed, as he always ought to have been, unnoticed in the showyard at Bridlington. Of those present were Lady Derwent, who, with all her good looks, does not strike us as a hardy one or a stayer, and we are much mistaken if she is not more in her element in the show-yard than she would be in the hunting-field. Sprig of Nobility, a taker of a hundred at Islington one year and as handsome as ever, had not his chance improved by the assistance given him by the gentleman up, and who, if we mistake not, did not show him to advantage at Thirsk, and never will. Then the popular candidate for Parliamentary honours, Mr. C. Sykes, had half-a-dozen very useful weight-carriers; but they were not duly elected, although a heavy weight in search of a horse to represent him at the end of a run, may trot some miles about the country before meeting with such likely animals as The Colonel, Eta, and Gardener. Mr. Johnson's (of Lowes-thorpe) chesnut by Canute was a capital stamp of horse, with power, length, quality, good ends, and short honest-looking limbs, and he moved quick, strong, and well, without fuss. If we mistake not, he would leave Lady Derwent and many others the other side of Jordan in a long thing. Sir W. L. Hudson's Highborn, with something of the General's cut about him, but not so grand, is

a very taking animal, but rather light below the knee; while Emperor, of Mr. Stephenson's, though compact, well-set, strong, and hardy-looking, has a temper of his own, or his eye belies him. Garland belonging to Mr. Snarry of Malton, was a light corky gentleman; Mr. Smith's Two per Cent., and Mr. Bowman's bay by Lancelwood, are nice-looking ones; while Trident pleased us best of the Orpheus get, but more so when standing still, as he is not a strong goer. After some sorting, Lady Derwent, Highborn, and Emperor were picked out and ridden by the judges; the cup after some deliberation being given, as it had been before by some of the bench, to Lady Derwent, Highborn and Emperor being decorated with the green riband. We should have much liked to see the President's string stripped, as there was some genuine-looking metal amongst them, many being stamped with the Hall mark in the shape of scars or the irons. Wrangler, a thoroughbred in his sixteenth year, though penitent about the knees, was a varmint, active, wiry-looking old fellow, of a rare stamp; as was the lengthy short-jointed Doctor, who was full of character. Then Straight Stick, the Orphan, and several more were worthy of being seen, as they would have been if the show had been properly conducted, and the time not taken up in guzzling and turning a show-yard into a Cogers Hall for spouting at mid-day. People don't go to Cogers Hall to see horses, or come to a horse show to hear speeches; at least we don't.

The eight pounds for thorough-bred hunting stallions brought the well-known Angelus, who took the royal hundred at Leicester, where we gave a description of him, that we had often given before. He is a favourite with many of the Yorkshire farmers, because he is such an eye-full. He was looking much better for his sweat at Leicester, having got rid of a deal of unnecessary flesh. Theobald, a chesnut horse, well put together, and, if as good in his forelegs as he is in his hind ones and elsewhere, would be difficult to beat—and he is now anything but a bad one—was well worthy of second honours, and of first at Bridlington, where he beat the lengthy, good-ended, short-limbed, though lightish-middled, Strathern. Theobald is by Stockwell, dam by Red Hart, but he never did anything on the Turf. He was christened after the sporting old hosier of Snow-hill, and breeder of Stockwell, whose blue coat and brass buttons, bulky, saffron-coloured leathers and roomy tops must have been familiar to many. Then came the long, hollow-backed, rather grand-looking Cathedral by Newminster, out of Stolen Moments by Melbourne, and who, when on the Turf, scored three races out of ten, winning the Great Northern Handicap at York; the fourth being the rather neat, good-limbed, little Schuloff by Cossack, but whose staggering hind-leg action put him out of the bout.

The Coaching and Roadster Classes were well-represented, both in the stallion mares and young horses; the good-looking Inkermann beating the well-known Blondin, who in a smaller class was first at Bridlington. Among the Roadster Stallions were many well-known stagers, including the winner, All-Fours, renowned for his neatness and his movements, although ordered out of the ring at Thirsk last year before he had got fairly once round! The second horse is more cobby, with less quality—the thick-set, low, short-legged St. Ives, the first roadster at Bridlington. Mr. Smith's old mare Venture, as active-looking as ever though in her twentieth year, and the taker of forty-three prizes, added another to her long score; while Mr. Johnson, of Driffield, exhibited a very fine mare. The first three-year-old cocher was well made, on a short leg, and had a very fair match by his side, both being by Blondin; while the second prize was a leggy one, and not well put together. Polly, an old and a great aversion of

ours, a heavy-shouldered hammering cob, was the first roadster mare. There were several nice ponies, and the agricultural classes—all local prizes—were well-filled with the thick-set black active-looking cart-horses of the county. There was but a poor show of Shorthorns as to numbers, though there were some well-bred ones among them, the all-aged bull here being first at Burlington also, as well as one of Lady Pigot's breed. He is an animal of great size, and good to the touch. In the extra-stock the prize went to a pair of black Aberdeen Scots. There was but a handful of sheep, but little and good, Messrs. Borton, Riley, and Sharp opposing one another for Leicesters; while Mr. Dickson, of Nafferton, with a very good-looking pen, beat Mr. Foster, of Southburn. The Leeds pigs, with more prizes than pigs, had it all their own way, and they calculate beating the Leicester big boar at Wetherby, with Royal Oak.

## PRIZE LIST.

## JUDGES.

SHORT-HORNS, SHEEP, AND PIGS: R. Jefferson, Whitehaven, Cumberland; T. Marris, Ulceby, Lincolnshire; G. Smart, Aberford, St. Milford.

HORSES (THOROUGH-BRED AND HUNTERS): J. E. Bennett, Husband Bosworth Grange, Rugby; Edward Paddison, Ingleby, Lincoln; Charles M. Nainby, Great Grimaby.

COACHERS, ROADSTERS, CART, &c.: G. Wightman, Fulwood Park, Preston; R. P. Hamilton, Asenby, Thirak; T. Potter, Trowell, Nottingham.

## SHORT-HORNS.

Bull of any age.—First prize of £10, William Linton, Sheriff Hutton (British Hope); second of £5, William Linton (White Windsor).

Bull calf under twelve months old.—Prize of £3, John Cattley, Stearsby, York (Prince Leopold).

Cow in-calf or milk.—First prize of £5, William Linton (Lady Valentine); second of £3, Executors of the late F. Jordan, Eastburn (Cucumber).

Two-year-old heifer for breeding.—Second prize of £2, T. Dawson, Poundsworth (Snowdrop).

Heifer calf under twelve months old.—Prize of £2, T. Dawson (Miss Flyte).

Fat ox of any age or breed.—Prize of £2, Executors of the late F. Jordan.

## SHEEP.

Shearling ram.—First prize of £10, and second of £5, John Borton, Barton House, Malton.

Pen of three shearling rams.—First prize of £5, Edmond Riley, Kipling Cotes, Beverley; second of £2, J. W. Sharpe, Ulrome, Lowthorpe.

Aged ram.—First prize of £5, Edmond Riley; second of £2, John Borton.

Pen of five breeding ewes, bred in the Riding, having had lambs in 1868, and suckled them up to the time of showing; the lambs to be shown with the ewes.—First prize of £5, John Dickson, Nafferton; second of £2, J. W. Foster, Southburn.

Pen of five shearling wethers, bred in the Riding.—First prize of £4, and second of £2, Executors of the late F. Jordan.

## HORSES.

Stallion for thoroughbred hunters.—First prize of £6, Sir G. Cholmley, Bart., Boynton (Angelus); second of £2, H. S. Constable, Wassand (Theobald).

Stallion coach horse.—First prize of £6, F. Richardson, York (Inkerman); second of £2, M. Medd, Filey (Blondin).

Stallion for roadsters.—First prize of £6, H. R. W. Hunt, Dunnington, York; second of £2, J. Crompton, Thornholme, Lowthorpe.

Stallion for agricultural purposes.—First prize of £6, W. Simpkin, Burton Agnes; second of £2, G. Lamplough, Nafferton.

Mares and foals for hunting.—First prize of £5, Mark Leaper, Sledmere Field; second of £2, G. C. Jarratt, Harpham.

Two-year-old hunting gelding or filly.—Prize of £3, W. Brigham, Beverley.

Yearling hunting gelding or filly.—Prize of £2, Sir G. Cholmley, Bart., Boynton.

Mare and foal for coaching.—Prize of £5, John Smith, Marton Lodge, Bridlington.

Coaching mare without a foal.—Prize of £3, F. Richardson, Moor Town, Beverley.

Three-year-old coaching gelding.—First prize of £5, J. Milner, Middledale, Kilham; second of £2, S. Simpson, Dringhoo.

Two-year-old coaching gelding.—Prize of £3, G. Walmaley, Bridlington.

Yearling coaching gelding or filly.—Prize of £2, John Johnson, Brigham, Driffield.

Coaching filly under four years old.—Prize of £4, J. Stephenson, Winstead, Hull.

Roadster mare and foal.—Prize of £5, William Major Sledmere (Polly).

Roadster nag or mare.—First prize of £5, F. P. Newton, Norton, Malton; second of £2, G. Gale, Atwick, Hull.

Three-year-old roadster nag or mare.—Prize of £3, A. Cranswick, Thornholme, Lowthorpe.

Ladies' pony under 14 hands.—Prize of £3, L. Logan, Lockington, Beverley (Dandy).

Pony not exceeding 12 hands.—First prize of £1, J. E. Moore, Cowden, Hornsea (Joe); second, a whip, J. W. Topham, Bainton.

## AGRICULTURAL PURPOSES.

Mare and foal.—Prize of £5, J. W. Sharp, Ulrome (Jet).

Three-year-old gelding or filly.—First prize of £5, George Chatterton, Coniston; second of £2, John Crompton, Thornholme.

Two-year-old gelding or filly.—Prize of £3, Executors of the late F. Jordan.

Yearling gelding or filly.—Prize of £2, W. Ulyott, Great Kelk.

Pair of horses of either sex regularly worked up to the time of showing.—Prize of £5, John Simpson, Hunmanby.

## PIGS.

Boar, large breed.—Prize of £2, John Dyson, Leeds (Royal Oak).

Sow, large breed.—Prize of £2, John Dyson, Leeds (Morning Star).

Boar, small breed.—Prize of £2, John Dyson, Leeds.

Sow, small breed.—Prize of £2, John Dyson, Leeds (Dew-drop).

Store pig, the property of a labourer or working mechanic.—Prize of £2, Thomas Dawson, Westgate, Driffield.

## SPECIAL PRIZES.

A silver cup, value £25, four-year-old hunting mare or gelding, the animal to possess not less than three crosses of blood (open to all Yorkshire), to J. B. Booth, Killerby Hall, Catterick (Brigadier).

A silver cup, value £25, all-aged hunting mare or gelding (open to all England), to E. Hornby, Flotmanby, Ganton, York (Lady Derwent).

A silver cup, value £10, three-year-old hunting gelding or filly (open to all Yorkshire), to H. Lambert, Wauldbby, Welton (Syringa).

A silver cup, value £10, yearling bull (open to all England), to W. Linton, Sheriff Hutton (White Windsor); second, £3, to J. S. Jordan, Elmswell (Jerry).

A silver cup, value £10, pen of five shearling gimmers, bred in the Riding (open to the East Riding), to E. Riley, Kipling Cotes, Beverley.

DRY SUMMERS.—In 1818 wheat was brought into market, in the south of England, on the 12th of July, and there was no rain until the 6th of September. In 1822, corn was cut and carried on the 5th of July, and the rainfall commenced on the 15th of August. In 1826, the straw of the oats was so short that it could not be reaped: it had in many places to be pulled up with the roots, yet there was never, perhaps, seen a heavier sample.

## THUNDER STORMS.

The effects of thunder-storms on arable and grass lands are very various, heavy showers of rain often doing an immense harm in one field, but good in another. And besides their direct action, they also teach the agriculturist lessons of an indirect character, which ought not to be lost sight of at a time when the public mind is, from the one end of the kingdom to the other, deeply engrossed with the utilization of town sewage.

Thoroughly drained land, either naturally or artificially, swallows up the heaviest shower of rain as fast as it falls upon the surface of a newly or recently cultivated field, as a field of potatoes, mangolds, or turnips. In this way all superfluous water percolates through the staple into the subsoil below. We have seen very heavy thunder-showers thus removed from clayey land, such as that which fell on the 29th May, in the neighbourhood of the metropolis; but in other examples, where the land was also under-drained equally close, we have seen sad havoc played, not only to the newly-braided crops, but also to the land itself; and the difference in the effects thus produced gives rise to many important questions in the raising of green crops, of which the following may be taken as special illustrations.

Thus the question is raised as to whether broadcast or drilling on the flat is less subject to harm from thunder-storms than growing green crops on the ridge system now generally practised? And as thunder-storms are more common in our southern provinces than in our northern, whether they had any effect in determining the growth of green crops on the flat, generally practised by our ancestors in the former, and on the ridge system in the latter?

Generally speaking, land when raised into ridges for drilled green crops is more liable to be washed away than the same quality of land when lying on the flat. This arises from the ridges collecting the water into currents, so that whenever such take place much harm is done. But, on the other hand, when by proper subsoiling the rain-water can be filtered off as fast as it falls into the drains, thereby preventing currents, less harm is sustained under the ridge system than under the flat system, clayey land disposed to run together being less consolidated in examples of the former than of the latter. Again, on steep inclines the prevention of currents will be less or more determined by the direction of the ridges.

Another question arises for solution, one too, which demands special attention, viz.: Is the manure in the land less liable to be washed away under the ridge system than under the flat system? Now that so many artificial manures are being used of a soluble nature, this is a very important question, and the odds, if any, we aver, are here again in favour of the ridge-system when it is properly carried out. The greatly increased breadth of land now being cultivated on the ridge-system may be taken as experimental evidence in support of this conclusion.

With regard to the harm sustained by young mangolds, &c., they are perhaps more at the mercy of the storm than the land on which they grow or the manures on which they feed. When they strike their roots deep into the soil, and are otherwise healthy, they suffer less than when the roots creep along the surface as it were, a fact which forms a practical argument in favour of growing green crops upon half farm-yard manure and half bones, or other artificial fertilizer, for under this method the young mangolds, swedes and turnips not only strike their roots deeper, but otherwise acquire a greater hold of the land during that period of their growth when they are most at the mercy of the thunder-storms, and the blistering action of scorching suns, when their tender leaves are less or more plastered over with soil.

Heavy thunder-showers also, less or more, earth-up young corn plants, and wash away the soil when the rain-water is allowed to collect into currents, but owing to the nature of such crops a less degree of harm is sustained than is the case with green crops. Peas and beans, however, often suffer much harm. Hoeing often grants much relief; and if the last

hoeing has been given under ordinary calculation, an extra turn of the hoes may do more than cover the extra expense incurred. Wheat and rye crops, and indeed all corn crops when far advanced in growth, are very apt to be laid and battened into the ground in such a manner that the portion thus beat down flat to the surface never rises up again, consequently the subsequent vertical growth which takes place forms what is in some districts technically termed "a knee." The portion thus lying flat is more liable to disease, and, in point of fact, is almost invariably less or more diseased, and in wet weather much of it is even rotted. In other examples, the crop thus laid nearly all rises up so as to preserve health; but as the stalks are all bent towards the ground they thereby acquire more strength in one direction than in the opposite one, consequently they become twisted and laid in all directions by subsequent storms, from different points of the compass. In many seasons both these effects are produced in one and the same field, giving rise to no end of difficulties in the harvest-time in the removal of such crops from the ground, either by the scythe or reaping-machine.

Hay crops are similarly liable to be beat down flat to the surface of the ground, and to be rotted or twisted about in every direction the wind blows. The rank, uneven stubble in mowing-time is mostly attributable to the kneeling of the stalks towards the bottom, owing to the grass having been laid by heavy rains when in a young succulent state. When ryegrass is not very thick upon the ground, the heavy thunder shower raises the earth so as to soil the lower portion of the stalks in a manner very injurious to the edge of the scythe, if the soil is not washed off by gentle showers afterwards, or is otherwise removed by the action of the wind. When imperfectly drained, or not drained at all, tenacious clay-lands seldom absorb a thunderstorm as fast as it falls: hence, less or more washing takes place. In such cases a twofold effect is produced; for the crop is not only laid flat, but washed in a manner injurious to its present and future health, generally speaking. In some exceptional cases of bad health, washing may do good, as will be noticed under the next paragraph.

On grass lying in permanent pasture, heavy thunder showers do comparatively little injury, even on sloping clayey ground, which does not absorb them so fast as they fall. The flowing water in such cases, especially in unhealthy ground, floats off not only the small seeds of innumerable weeds, but an amount of animal life almost incredible to those who have not examined the water thus carried, under the microscope or magnifier. On comparatively level ground, where the water stagnates for a time, but does not flow upon the surface, the small seeds of weeds, spores of fungi, eggs of insects, and the life-germs of innumerable "microscopic little bodies" are washed into the soil, and thus perish in the form of manure to the land. A great deal of speculation has been advanced relative to thunder-showers bringing down from the clouds ammonia and so forth; but without deducting one iota of truth from such conclusions, we do not hesitate to say that a great deal too little has been said about the fertilizing properties of thunder showers as above, either by the washing or rotting process; and of the two, the latter is doubtless to be preferred. Hence the greater benefits experienced by the proper drainage of pasture-lands, or lands that are naturally drained, which permit of all such animal and vegetable life being washed into them for manure, during the decomposition of which much ammonia or nitrogenous matter is formed. Heavy thunder showers also wash into the soil much animal and vegetable filth of the above nature from other crops besides grass, when the land is properly drained.

Indirectly, heavy thunder-showers read the farmer a lesson, which ought not to be thrown away, in the utilization of town sewage; for what is a thunder shower but liquid-manuring, not only on the hose-and-jet principle, but also on that of gravitation, the solid matter being removed in both cases. To fallow-lands or stubble-lands this would not be necessary and so on.

## REVIEW OF THE PROGRESS OF CHEMICAL AGRICULTURE.

[TRANSLATED FROM THE FRENCH.]

M. Hellriegel, Director of the agricultural station at Dahme, in Prussia, recently communicated to the editor of the *Landwirtschaftliches Central Blatt* the results of some very interesting experiments upon vegetation. The author purposed determining by experiments the influence of the bulk of the soil put in connection with roots upon the weight of the crops.

M. Zöller in some researches, of which we shall speak more particularly at a future time, made known to the public last year the result of some experiments undertaken for the same purpose. The plant chosen for trial was the haricot, and it showed that, all other things being equal, a certain quantity of earth obviously gives the same weight of crops, whether we put into the soil one, two, three, or four plants at a time.

Some jars of equal dimensions, filled with pure peat, peat and manure, and garden mould, gave the following crops expressed in grammes [The numbers 1, 2, 3, and 5 show the number of stalks on the haricot in each experiment]:—

SOILS.	1.	2.	3.	4.	5.	Average.
	Gr.	Gr.	Gr.	Gr.	Gr.	Gr.
Pure turf .....	24.5	26.4	26.3	29.4	28.9	27.0
Turf and manure .....	90.4	89.6	92.8	90.1	93.3	91.6
Garden earth .....	—	40.1	43.4	44.9	—	42.1

M. Hellriegel's experiments were made in the summer of 1864 upon some oats in pots of three different dimensions, filled with garden mould. The three parallel series comprised twenty-four experiments each, the pots containing respectively from 1 to 24 grains each. The following very important results were brought to light by the experiment:—

**FIRST SERIES.**—Dimensions of the pot: height, 56 to 58 centimetres; diameter outside, 15 to 16 centimetres; diameter inside, 12 to 15 centimetres; weight of earth contained in the pot, 12 kilogrammes 500:—

No. of stems per pot.	Crops per pot. Dry substances in grammes.		
	Grain.	Straw.	Total.
1	14.820	18.338	33.158
2	15.119	16.193	31.312
4	18.786	20.713	39.499
6	18.533	20.401	38.934
8	20.255	21.590	41.815
12	20.807	20.748	41.555
16	20.496	20.885	41.181
24	21.072	20.582	41.654

No. of stems per pot.	Crop per weight, as per kilogramme of earth.		
	Grain.	Straw.	Total.
1	1.188	1.467	2.653
2	1.210	1.296	2.506
4	1.503	1.657	3.160
6	1.483	1.632	3.115
8	1.618	1.727	3.345
12	1.604	1.660	3.324
16	1.640	1.665	3.295
24	1.686	1.646	3.332

It will be seen that in these experiments the weight of the crops remained the same, as there was the same quantity of earth for 8 or 24 stalks of oats. The preceding numbers show that the constancy of the return takes place, not only for the total crop, but also for the straw and grain taken separately. The same law is observed in trials made with pots of much smaller dimensions.

**SECOND SERIES.**—Height of base, 28 to 29 centimetres; diameter above, 14 to 15 centimetres; diameter below, 11 to 12 centimetres; weight of earth, 5 kilogrammes:—

No. of stems per pot.	Grain.	Straw.	Total.
1	9.105	8.163	17.268
2	10.130	9.556	19.686
4	10.960	9.459	20.419
6	11.865	9.917	21.782
8	12.769	9.758	22.527
12	11.956	9.410	21.336
16	11.916	10.402	22.318
24	12.409	12.013	24.422

No. of stems per pot.	Grain.	Straw.	Total.
1	1.821	1.633	3.454
2	2.026	1.911	3.937
4	2.192	1.892	4.084
6	2.373	1.983	4.356
8	2.554	1.951	4.505
12	2.391	1.882	4.273
16	2.383	2.080	4.463
24	2.432	2.402	4.834

**THIRD SERIES.**—Dimensions of pot: height, 13 to 14 centimetres; diameter above, 13 to 14 centimetres; diameter below, 11 to 12 centimetres; weight of earth, 1 kilogramme 667:—

No. of stems per pot.	Grain.	Straw.	Total.
1	4.054	3.647	7.701
2	4.645	4.692	9.337
4	4.351	5.051	9.402
6	4.498	4.050	8.548
8	5.316	4.709	10.025

No. of stems per pot.	Grain.	Straw.	Total.
1	2.432	2.187	4.619
2	2.780	2.815	5.601
4	2.610	3.030	5.640
6	2.698	2.430	5.128
8	3.189	2.825	6.014

These numbers clearly show that the quantity of earth in which the roots can develop and extend themselves determine the yield of the soil. It will be seen that when we grow in a given quantity of earth a number of stalks of a vegetable corresponding to the maximum of the crop, we cannot increase the yield of the soil by adding to the number of the plants: the greater the extent of earth, the smaller is the return per kilogramme. M. Hellriegel thinks the results of these three series of experiments will be better explained in the following words: The produce of a given weight of earth will be in inverse proportion to the cubic roots of the size of the earth.

The volumes of the three series of pots used by M. Hellriegel are between them as 7.5, 3, 1; the cubic roots of these three numbers are respectively 1.93, 1.36, 1. If we compare the four last figures of each of the series, we find the average to be as 3.324, 4.512, 5.913 = 1, 1.36, 1.93—that is to say, very nearly what it would be, supposing the hypothesis of M. Hellriegel to be correct.

Subsequent experiments showed the author, and those who repeated his method, that his report exactly represented the phenomena. But I must hasten to say that that is only secondary; and whatever may be the modification it is neces-

sary to bring to the hypothesis of M. Hellriegel, the very curious facts his researches have put in evidence will not be the less acquisition to science. Let me add that I was enabled, during a visit recently made at the station of Datune, to estimate the rigour, precision, and great cleverness displayed by M. Hellriegel in his works. He has, with good reason, been mentioned as one of the most distinguished chemists in Germany.

Permit me to say a few words more upon a communication recently made by the same experimenter, with regard to the influence of azotized mineral manures upon cereals. Last November, M. Hellriegel stated, at a meeting of agriculturists held at Frankfort-on-Oder, the results of some experiments, the perfect correctness of which I can guarantee, from personal inspection. These trials of the culture of cereals in calcined sand, chemically pure, and added to different doses of mineral manure, showed most clearly the influence of azotized mineral matter upon vegetation, and confirmed the generally admitted idea of the non-assimilation of azote by plants from the air.

Some experiments, made prior to those of which I have spoken, taught M. Hellriegel that 70 parts in weight of assimilable azote contained in a million parts of earth, is sufficient to obtain a maximum yield of wheat; and it would require only 63 parts of azote in the same weight of earth to obtain a maximum crop of rye. If the weight of azote diminish, the yield will decrease according to a geometrical progression.

In the following table the maximum crops are represented by 100 for wheat, and 90 for rye. The yields obtained in the trials are indicated by figures representing grammes, on the opposite side of which are inscribed the theoretical yields calculated upon the basis previously mentioned:—

## 1ST, WHEAT.

1,000,000 grammes of earth containing assimilable azote.		Returns.	
Gr.	Obtained.	Gr.	Calculated.
70	100	70	100
56	77	56	80
42	64	42	60
28	41	28	40
21	30	21	30
14	19	14	20
7	7	7	10
2ND, RYE.			
63	90	63	90
56	74	56	80
42	54	42	60
28	43	28	40
21	28	21	30
14	20	14	20
7	9	7	10

The returns obtained are shown in abstract by decimals, to render the comparison more easy. The agreement between the real and calculated yields is so great that we may deduce the following law: In certain conditions of culture, the returns in rye and wheat are in direct proportion to the quantity of assimilable azote contained in the soil. M. Hellriegel adds that the results of experiments made with barley and oats were precisely the same; so that the same law will be applicable to all cereals, without distinction. We resume these important researches, in the practical knowledge we are constantly gaining on the trial fields.

The preparation of fodder is an important thing. The nutritive properties of hay vary in proportion to the manner in which it is prepared. Professor Voelcker recently published a paper upon the rational preparation of fodder, accompanying his observations by analyses which appear to us of real interest to practical farmers. It is evident that if we could prepare hay without modifying the composition of the plants harvested, we should obtain a dry fodder equal in value to the green grass from which it is made. Under the influence of the rays of the sun, clover and grass lose nothing but water, and their constituent elements sustain no injury if the plants are not too tender and if they are not dried too rapidly: the green colour, sapidity, and aromatic odour of hay well preserved sufficiently

attest this truth. The preparation of hay does not necessarily take away the nutritive properties from it; but many practical men maintain that there is less nourishment in hay than clover and other herbaceous vegetables in a green state; however, if that be true in nine cases out of ten, it is not absolutely necessary.

If artificial desiccation could be practically applied, or if we could even thoroughly superintend the desiccation in the open air, hay would lose none of its nutritive qualities; the green colour would be preserved, the watery particles alone evaporate, while the solid elements would remain in the hay just in the state they are found in fresh fodder.

According to an eminent English agriculturist, the alteration of grass during its transformation into hay may be traced in most cases to the following causes:

1st. Rainy weather prevailing for a long time after the fodder is cut; damp and half-dry grass often remains too long in heaps before it can be moved and spread.

2nd. Heating, from being put in heaps upon the soil.

3rd. Being cut at the wrong time—either too soon or too late.

When grass and clover are fit to cut, they contain a considerable proportion of sugar, gum, pectine, albumen, and other soluble substances, all of which may be washed away by heavy rains. Whilst grass is in a fresh state rain does not injure it, because the epidermis is clothed with a matter similar to wax or grease, which forms a sort of mantle against the rain. In consequence of the existence of this protective envelope, in may rain for a long while upon grass recently mown without much injury resulting from it; but it is altogether different when the plants have been turned several times and bruised by the rake. In that case the rain falls upon hay half-made, and it not only carries away the sugar, gum, and other soluble principles; but penetrating to the interior of the vegetable through the breaks in the cells, it causes a fermentation to take place, which if not promptly arrested may end in a considerable loss of nutritive matter. The sugar and soluble albumen—two most valuable elements—are destroyed by fermentation. It is therefore necessary in rainy weather to turn grass recently cut as much as possible, and in every case all necessary precautions should be taken during that operation to avoid tearing the fibres of the plant. Simple as the preparation of hay appears to be, it requires considerable experience to know exactly the conditions under which grass should be mown, turned, and put into cocks. It often happens that a farmer turns his hay upon a dull day, when the air being saturated with damp no evaporation can take place. At such a time it is not only useless but even injurious to turn hay half-dry, because by bruising it he puts it completely under the pernicious influence of the rain. It is a well known fact that hay badly dried in the meadows loses both in weight and quality when stored; but the nature of the injuries produced after it is put in cocks, or housed, through heating and fermentation, is not so well understood. It is principally upon these two points that Mr. Voelcker has directed his observations.

According to Way, the average composition of clover is as follows:

	Fresh.	Dried to 100 degs.
Water	16.60	—
Fatty matters	3.18	3.81
Albumen and analogous principles*	15.81	18.96
Gum, sugar, carburetted hydrogen (readily transformable into sugar)	34.42	41.27
Cellulose	22.47	28.95
Mineral matters	7.52	9.01
	100.00	100.00
*Containing of azote	2.53	3.03

These results represent the average of 75 analyses of clover and some other plants which are generally mixed with it: the plants accidentally mixed with clover presenting a variable composition, the figures we give must be regarded as merely a general indication. We must also bear in mind that the composition of fodder varies with the nature of the soil, the time of the harvest, &c. It is however certain that clover contains a little more water than grass, all things being equal;

and it is also a little more rich in sugar and carburet of hydrogen; but it differs mostly from grass by its strong hold of the azotized principles which tend to the formation of flesh in animals.

The average of 25 analyses of fodder, obtained from natural meadows, gave M. Voelcker the following results:

	Fresh.	Dried to 100 degs.
Water ... ..	14.61	—
Fatty matters ... ..	2.56	2.99
Azoteous matters* ... ..	8.44	9.88
Non-azoteous matters, sugar, gum, &c. ...	41.07	48.09
Cellulose ... ..	27.16	31.80
Mineral substances ... ..	6.16	7.24
	100.00	100.00
*Containing azote ... ..	1.35	1.58

Fodder made from clover or grass contains a certain quantity of sugar, quite formed, or of another soluble carburet of hydrogen, which, under the influence of ferments, is easily transformed—first into sugar, then into alcohol, and carbonic acid. The albuminous and other azoteous principles found in fodder, partly in a soluble and partly in an insoluble state, are equally important. It is by means of these substances coming in contact with the air that the ferments are developed which cause the decomposition of hay; and that explains why fodder which has been submitted to active fermentation generally loses its nutritive properties, because the materials destined for the production of flesh in animals is transformed into sugar, which destroys itself soon after. Sugar, we know, can only ferment in a sufficiently concentrated solution. The large quantity of water existing in fresh-cut clover or grass prevents fermentation, while, on the other hand, the azoteous substances do not permit the ferments to develop themselves till life has ceased in the vegetable—that is to say, when the cells and vessels, bruised by the desiccation, enable the liquids they contain to become mixed. In proportion as the plant dries and loses its vitality, the conditions favourable to fermentation increase. During the process of desiccation, hay contains at a certain time water and sugar in exactly the proportion required for fermentation.

The consequence of these facts is as follows: If through unfavourable meteorological circumstances the housing of fodder is interrupted, or the atmosphere remains damp for some weeks, the half-dry hay begins to decompose on the spot, deteriorates in quality, and becomes predisposed to heat in the stack. On the contrary, if the weather is fine and warm, so that desiccation takes place rapidly, the rate per cent. of damp soon falls so low that fermentation cannot take place. The hay remains upon the ground and cannot easily become heated, even though in reality it contains more water than fodder harvested in bad condition. The more rapidly hay is turned to the sun the less it will be bruised, and the greener it is the better it will resist fermentation when it is stored; nevertheless, it often happens that a too rapid preparation injures fodder, and in a good year hay appears to be saved in fine condition when in reality it is not. If hay be carefully and completely dried by the sun it never heats; a slight fermentation, far from being deleterious, is often very useful—in fact, we know that in such a case certain aromatic principles are produced which render fodder more sapid, and perhaps even sometimes more nourishing. As long as the green colour remains, the hay has lost none of its quality; when it is much heated it turns brown. Some cultivators prefer brown to green hay, and it is certain that the former frequently has more flavour and smell than the latter; but, though cattle prefer brown hay, it is not at all desirable to leave sufficient moisture in the fodder at the time it is housed to turn it brown, because the loss resulting from fermentation is not counterbalanced by the slight aromatic smell it acquires.

M. Voelcker says: "Some years ago I had occasion to examine some brown hay which possessed an aromatic smell like fruit; it had a palpably acid savour, contained no traces of sugar, but a great deal of pectine, some brown matter analogous to humus, and a small quantity of soluble albumen. The acidity, I proved by analysis, was due to the presence of acetic acid. The hay was broken, of a dark brown colour, and a chemical examination gave the following results:

Water ... ..	18.33
Fatty matters ... ..	1.70
Soluble albumen, corresponding to 0.31 of azote ...	1.94
Pectine, gum, extractive matter, traces of sugar ...	9.94
Acetic acid ... ..	1.93
Assimilable fibrine ... ..	23.01
Insoluble albumen, corresponding to 1.40 of azote ...	8.75
Cellulose ... ..	28.53
Soluble mineral matters ... ..	3.98
Insoluble mineral matters ... ..	2.59
	100.00

Now we know that the use of such hay as food for cattle must be injurious. Another time M. Voelcker had occasion to examine some clover which had heated from the centre of a cock that they were obliged to pull to pieces. It had been harvested in bad weather, and made into cocks when it contained too much moisture. When the cock was pulled down, a vapour escaped of a peculiar smell, which stung his eyes. The vapour exactly resembled that produced in the manufacture of vinegar, denoting the presence of aldehyde. The hay presented the following composition:

Water ... ..	38.02
Fatty matter ... ..	0.90
Soluble albumen, corresponding to 0.30 of azote ...	1.88
Gum, pectine, extractive matter, and traces of sugar ...	6.63
Assimilable fibrine ... ..	15.55
Insoluble albumen, corresponding to 0.30 of azote ...	8.12
Cellulose ... ..	22.33
Soluble mineral matters ... ..	3.96
Insoluble mineral matters ... ..	2.61
	100.00

To complete these interesting observations of M. Voelcker, we quote the following results obtained by Dr. Beyer. That chemist analyzed two specimens of clover saved from the same crop, one of which had been properly desiccated, whilst the other had been exposed to the rain for three weeks. A hundred parts of each of these clovers, dried to 100°, contained:

	Clover.	
	not wet.	wet.
Fat matters ... ..	3.225	1.010
Cellulose ... ..	36.200	39.866
Proteinic matters ... ..	11.872	8.662
Mineral matters ... ..	6.115	4.719
Matters deprived of azote ... ..	42.588	45.743
	100.000	100.000

That analysis showed that rain acts in an injurious manner, particularly upon the substances most important as regards alimentation, since the action of the water destroys the fatty and other protective matters, such as albumen, &c., which cover the stalk.

M. Beyer analysed also the ashes of these two specimens of hay. There was no sensible difference in their composition, but the rain had carried away a certain quantity of mineral substances. The potash, lime, and phosphoric acid were diminished one-fourth in quantity, and the magnesia nearly a third. The insoluble matters, which are certainly of very little value as food, were sensibly increased.

The preceding accounts show how much care is necessary in the cutting and saving of fodder. If the cultivator cannot completely guard against the inconveniences resulting from bad weather, he may at least draw from the facts we have reported some useful hints upon the accidents to be avoided, and the best methods of preparing fodder.

Amongst the problems, the solution of which presents the greatest interest to physiology as well as agriculture, the study of the chemical phenomena of nutrition occupies an important position. What influence has alimentation upon the raising and fattening of cattle? What transformations do the different aliments undergo in the bodies of the animals to which they are given? These are undoubtedly two of the grandest problems biological chemistry can resolve. The physiological laboratories at the agricultural stations in Germany have for the last ten years been the theatre of some most interesting researches upon this important subject. Voit, Fettekofer, Hennaberg, Stohmann, Kühn, and many other celebrated ex-

perimenters have already solved some important points of that complex mystery, nutrition, and the formation of fat, fibrin, &c., in animals.

The aliments introduced into the body of a living being are submitted to various modifications there, the effect of which is to render part of their principles assimilable, whilst the other matters, which are non-assimilable, are cast away under the form of feces and urine. The respiratory organs play an important part in these transformations; and the analysis of gas thrown off by the lungs has for a long time been regarded by physiologists as one of the most important principles to register correctly.

In spite of the works upon that branch of science, which we owe to MM. Regnault and Beiset, Beschoff, and Voit, Planet, Valentin, and others, up to the last few years, there still reigned much uncertainty upon the fundamental points of the question. The reason of this is that, before the construction of the large respiratory apparatus by M. Pettenkofer, to which we shall refer presently, the methods employed by these savans I have named, were very imperfect. In fact, there were two grand faults in all the processes in use up to the last few years, for studying the respiration of man and animals.

In the first place, the experiments were made under anomalous conditions—that is to say, not in places where the animals chosen for the study of the phenomenon of respiration were accustomed to live. For instance, they were generally shut up in confined spaces, where the air could only be completely renewed in summer.

In the second place, another unfavourable circumstance was that none of the methods employed could be controlled. The state of our knowledge upon that point, then, required for the complete solution of the problem, an apparatus into which the man or animal submitted to experiment could remain twenty-four hours or more, without inconvenience—a chamber where they might walk about, eat, and sleep with ease—in fact, live without constraint, and in their usual condition.

It is also necessary that the air should be suitably renewed, and that that air be analyzed at its entrance and exit, and should be measured exactly. By that means the dose of carbonic acid, vapour of water, and other gaseous products exhaled from the lungs and skin could be obtained by taking the difference in the quantity of these elements existing in the air before and after its passage into the apparatus. An analysis made under such conditions would be very advantageous, as it would remove the causes of error in the dosage of carbonic acid and water, since those causes, of little consequence otherwise, influence the analysis of gases equally at their entrance and exit.

M. Pettenkofer's apparatus possesses all these advantages. With the help of it, immense works have been accomplished by M. Voit and other experimenters. We should like to make known to our readers the important results of these works; and in order to do so thoroughly, it is necessary to commence with a description of M. Pettenkofer's apparatus.

When on a journey through Germany, Professor Henneberg, manager of the station at Weende, kindly allowed me to witness an experiment made upon two sheep. I was thus enabled to judge the correctness of the method, and hope to be able to give a clear idea of the apparatus and manner of dosing the carbonic acid, water, hydrogen, and marsh gas, though here I am at fault, for want of a representation.

It is an important question, and one many times discussed, without however arriving at any positive solution—to know in what proportions, and how often, the air in which a man or animal is kept, should be renewed, in order to enable him to live conveniently and without disordering his functions. First let us state that the quantity of air necessary to a man varies generally with the physical disposition and temperament of the individual. Conclusions have been drawn relative to the renewing of air, from the quantities of oxygen, carbonic acid, and aqueous vapour contained in the air confined, which our daily experience and individual impressions frequently deny. All we know upon that point is, that in order to breathe easily in a confined space, it is necessary that the air of that space contain a much greater quantity of oxygen than is consumed in the act of breathing, and much less carbonic acid and vapour than is exhaled from the lungs and skin. What renders the air of a room crowded with people heavy and disagreeable, acts

upon the nervous system, and produces that uneasiness the effects of which vary from the simple headache to syncope, is not the heat alone, but the hygrometric state, the carbonic acid or want of oxygen in the air; in fact such an atmosphere seems to us enervating and poisonous, before being saturated with steam of water, having lost a quantity of its oxygen, and containing more than 1 per cent. of carbonic acid: the air is much the more disagreeable to us that it has been respired a greater number of times, because it is then charged with organic emanations thrown off by the skin and respiratory organs. It is thought that many of the vapours produced by the organism possess a very weak tension, so much so that the air is quickly saturated by it, and thus rendered unfit for respiration.

It is therefore evident that the experiments made upon animals in an atmosphere not entirely renewed, but only modified by the addition of oxygen at different times, and the absorption—by any means whatever—of the carbonic acid exhaled by the animals, does not present the necessary guarantee for correctness. On the other hand it is not necessary that the air be renewed indefinitely: it should be only in certain limits, as M. Pettenkofer has empirically endeavoured to establish. He determined what quantity the carbonic acid produced by respiration and cutaneous perspiration must exceed, in an apartment sensibly well aired, the weight of the same gas existing in the free air, before the organic emanations which accompany the rejection of carbonic acid from the skin and lungs act upon the sense of smell in an unpleasant manner. It was found that the proportion of carbonic acid, which in free air is, as we may say, 6 volumes in 10,060 nearly, may rise under the influence of the respiration of a man in confined air to 1 volume in 1,000 before that air acquires a disagreeable smell. As I said before, it is not the excess of carbonic acid to which we must attribute the deterioration of the air: we can only use that term comparatively to determine how many times the air contained in a room has been introduced into the lungs and rejected by them. In fact we may live very easily in an atmosphere containing 1 per cent. of carbonic acid, upon condition that the gas be obtained by chemical means. On the contrary, stopping in a place, the air of which contains 1 per cent. of carbonic acid, proceeding from respiration and perspiration, would be almost unbearable. The most infected air of prisons and barracks, &c., rarely contains more of it. Under almost any circumstances, the volume of air per hour necessary to a man rises to 60 cubic metres. M. Pettenkofer arranged his apparatus in such a way that he could introduce into his experimental room quantities of air that might be made to vary from 15 to 75 cubic metres per hour; the latter volume is sufficient for the largest animal that could be subjected to experiment.

I now come to the arrangement of the apparatus that I saw worked at Weende. The room destined to receive the man or animal is very nearly cubic; its volume is 12.7 m.; the surface of the floor is 5.452 m. The air is renewed by means of a ventilator, placed in such a manner that the current of air resulting from that renewal can never be inconvenient to the individual placed in the room. In fact it is only when the rapidity with which the air rushes into a place reaches 1 metre per second, that we find any unpleasantness from the current. Now, when M. Pettenkofer makes it 15 cubic metres per hour, the speed of the air entering is only 8 millimetres per second, and it only attains the figure of 0.0208 m. per second when the ventilator sends into the room 75 cubic metres per hour. We can easily estimate the changes of the volume occurring in the room from the presence of the man; in fact the variations due to pressure, temperature, and the hygrometric state, may be measured by the help of a barometer, thermometer, and psychrometer; besides which, the water may be collected and weighed.

It is not so easy to estimate directly the quantity of oxygen derived from the current of air by the act of respiration; but the observations of MM. Reynault and Reiset, Vierordt, Hutchinson, and others enable us to form some ideas on that subject, which at least border on the truth. The greatest part of the oxygen carried into the air by respiration in twenty-four hours, is thrown off under the form of carbonic acid; and, as a volume of this latter gas is per se equal to the volume that the oxygen it contains would occupy in the free state, it follows that there is no change in the volume of air which in the oxygen of that fluid serves only to the production of carbonic

acid. We know further that the volume of air expelled is rather smaller than that inhaled, because a part of the oxygen goes to the formation of steam and other oxygenized combinations.

If we admit that the mean volume of air introduced into the lungs by inspiration is equal, with a man, to 5 litres per minute, or 300 litres per hour, we find, by depending upon the numerous determinations of MM. Brunner and Valentin, that the average proportion of carbonic acid in the air expelled is  $m. 0.230$  per minute, or  $13.8$  per hour. By supposing that carbonic acid only represents two-thirds of the oxygen that has vanished, and that the third remaining served entirely for the production of water and compound oxygen, we have a diminution per hour in the volume of air inhaled in regard to that of the air expelled, which does not exceed 6.9 litres. If the volume of air in which a man has breathed for an hour is only equal to 10 cubic metres, the mistake committed by not taking count of that diminution will not be 1-19th per cent. It is therefore entirely negligible.

M. Pettenkofer, after having thoroughly studied those different questions, a previous knowledge of which was absolutely necessary, agreed upon the following dispositions for his apparatus: The air is measured at nearly 1-1000th of its volume, when it comes out, by a gasometer very carefully constructed. The ventilator constructed so as to introduce fresh air into the room at call, is worked by a small steam-engine. Some currents of air distributed laterally on the walls of the room enable the chemist to collect and analyze any quantity of gas that he wishes, at any stage of the experiment. The carbonic acid is dosed by a new process, which rests upon the rise of a liquor, called "baryta." That method of dosage, according to M. Pettenkofer, gives results that could not be obtained with the best scales, and enables the experimenter to discover the presence of 1-900th carbonic acid in a liquid.

The proportion of aqueous vapour is estimated by the help of sulphuric acid placed in tubes of a peculiar form, which I cannot here describe. The proportion of hydrogen and marsh gas contained in the air expelled is found by determining the excess over the normal quantity of carbonic acid and water, furnished by the gas previously thrown off from the body and conducted through a system of tubes lined with platina and heated red hot.

The great advantage that M. Pettenkofer's method possesses over others is, that it enables one to examine by direct experiments the results that it furnishes: the author has tested this many times.

By burning a certain weight of a fat body for a given time in the experiment-room—stearine for example—the composition of which is well known—the quantities of aqueous vapour and carbonic acid resulting from that combustion may be dosed, and compared with the weight of the same bodies obtained in the analysis of that substance by methods as exact as organic chemistry now possesses.

The figures I shall presently give leave no doubt as to the correctness with which M. Pettenkofer's apparatus works.

In five experiments where different quantities of pure stearine were burnt, in the room of the apparatus, the quantity of carbonic acid produced was dosed. Column 1 represents the quantities found experimentally, and column 2 the real weight of the same as given by direct analysis of the same quantity of stearine:—

Experiments.	1.		2.	
	Carbonic acid found.		Carbonic acid realised.	
1 ... ..	...	289.0	...	296.7
2 ... ..	...	229.0	...	229.1
3 ... ..	...	590.0	...	590.0
4 ... ..	...	286.0	...	288.7
5 ... ..	...	606.0	...	606.0
		2000.0		2070.5

The results obtained are between them in the proportion of 100 to 99.7. Such precision naturally inspires us with great confidence in M. Pettenkofer's method; it proves that his apparatus is as perfect as possible, and if we remember that to such exactness in the dosage of gases from respiration, the mode of experimenting adopted by the author, joins the possibility of putting a living being under experiment in conditions altogether analogous to those he encounters in ordinary life,

we may easily judge how valuable this new method will be to physiology.

I may add that the very extensive dispositions of the apparatus enable the experimenter to collect the urine and excrements of the animals under experiment, without any loss. We see that, thanks to M. Pettenkofer, we can now trace from point to point the phenomena of nutrition in animals while they are living in their normal condition. On the one hand, we can analyze all the products of respiration and cutaneous perspiration; on the other, we can collect all the matters not assimilated, and rejected in the form of feces and urine. The animal, weighed before its entrance into the apparatus and when it is taken out, receives a certain quantity of fodder, or any other kind of food; the manger is constructed so that none of the food can be lost, therefore all the conditions of the experiment are faultless.

At a future time I shall be able to show by accounts rendered what great progress has been made in the study of the raising and nutrition of cattle by the method I describe. At present I must limit myself to pointing out, in conclusion, the very curious and unexpected results shown by MM. Pettenkofer and Voit in their experiments upon the respiration of a man. These gentlemen discovered, in the gases proceeding from the respiration and cutaneous perspiration of animals, notable quantities of free hydrogen and proto-carbonated hydrogen (marsh gas) (1).

(1) It may be useful to remark that in order to gain the full value of that experiment, it should be proved that the carburetted-hydrogen dosed by these gentlemen did not proceed from intestinal gases.

The results of five experiments are as follows:—

Experiments.	Hydrogen.		Marsh gas.	
	Grammes.		Grammes.	
1... ..	...	7.2	...	4.4
2... ..	...	5.2	...	0.3
3... ..	...	7.2	...	4.7
4... ..	...	6.4	...	3.7
5... ..	...	4.3	...	4.6

These quantities relate to the products of respiration of the animals which have been kept a month or twenty-four hours in the experiment-room. MM. Pettenkofer and Voit have assured themselves, by certain tests, that these gases are due to the animals placed in the apparatus, and not pre-existing in the air introduced into the room by the ventilator. In order to confirm their opinion, they dosed the carbonic-acid and water contained in an enormous volume of air not calcined, then in the same quantity of air previously calcined, when the following results were obtained. In the first trial, during which 232,336 litres of air traversed the apparatus, they found in 1000 litres of air,

	Carbonic-acid.		Water.	
	Grammes.		Grammes.	
Calcined air ... ..	...	0.6782	...	10.9301
Non-calcined air ...	...	0.6776	...	10.9096

In the second experiment, which, like the first, lasted twenty-four hours, and carried over 228,516 litres of air, 1000 litres of air gave,

	Carbonic-acid.		Water.	
	Grammes.		Grammes.	
Calcined air ... ..	...	0.6440	...	10.6609
Non-calcined air ...	...	0.6444	...	10.6207

This proved that the air introduced into the apparatus did not contain any appreciable quantity of compound carburet, except carbonic-acid. In fact, in the first case after twenty-four hours test they discovered the presence of 0.75 grammes of hydrogen in 232,336 litres of air, or nearly 0.003 grammes per cubic metre.

In the second case 228.516 litres of air gave 1.02 grammes of hydrogen, or nearly 0.004 grains per cubic metre.

These figures, apart from the very curious result itself, show us how very exact M. Pettenkofer's method is, and how perfect the apparatus employed must be. In order that our readers may have an opportunity of learning the methods employed at Munich and Weende, I purpose at some future time touching upon the experimental results obtained by MM. Voit, Henneberg, Stohmann, and their disciples, in studying the nutrition of animals.

L. GRANDJEAN,  
Doctor of Science and M.D.

## THE ROOK.

The rook, a bird as much abused as if the whole business of his life was to rob and plunder; when the fact is, with the exception of seed-time and a very few weeks before harvest—that is, when the corn is ripening—he lives almost entirely upon worms, grubs, and caterpillars. Anyone who doubts the utility of the rook should consult Richardson on The Pests of the Farm, and he will soon come to a conclusion in their favour. This bird has peculiar instinct in discovering those pasture lands that are infested, and he will select the tufts of grass under which those concealed enemies lie. We have frequently seen, in a dry season, a piece of pasture which looked as if a heavy pair of harrows had been passed backwards and forwards over it, so numerous were the tufts of dried grass that lay upon the surface. But for the rooks there would have been no grass left! It was by the withered appearance of the tufts that the birds were enabled to judge of the pasture being attacked by the grub; and *only* those tufts were pulled up. On the estate of Mr. W. Oliver, the rooks were destroyed on this very account; but, on killing an old rook and examining his maw, there were found 19 large grubs and 17 wireworms: and this has been repeatedly the case where rooks have been shot during the season when the grain is not ripe. Why, for instance, does the crow follow the ploughman so industriously at his very heels, except to pick up the food in the shape of grubs, wireworms, slugs, with which alone they feed their young? The experiment has been tried to destroy or banish these birds, but it has always been a cause of bitter regret, for the immense increase of the insect tribes that followed their absence inflicted infinitely more injury than the rooks themselves would have done. Such is the case at this very moment in France, where, owing to the war waged against the birds, the communes are paying for the destruction of the cockchafer which in myriads are now ravaging the fields and woods.

It is true that the rook is a very cunning bird, and when attacking a corn-field, sentinels are always posted on the outskirts, to give notice of the approach of a gun, for he cares for nothing else. A boy, being provided with a pistol and powder *only*, was scolded for still allowing the rooks to commit their depredations. "Ye maun gie me lead," he replied; "for a wheen o' thae auld craws would sit on the vera point o' a pistol, gin I would let them." They must therefore be kept in check, as we have said, during seed-time and when the crops are ripening *only*, for at all other seasons of the year their food is insects, and the amount devoured in the neighbourhood of a numerous rookery is prodigious, while the good effected far more than makes amends for any other mischief.

What we have said of the rook may be repeated in the case of small birds—the larks, sparrows, and chaffinches; but for these the smaller insects—caterpillars, wireworms, and aphides—would devour all vegetation. Like the rooks, their young ones are entirely fed with insects, and until the grain is ripe their own chief food is the same. Still the sparrows and larks, however, must be kept in check, as well both to prevent an undue increase in their numbers and to guard the crops from their depredations; but to destroy them, as was the practice in France and Germany a few years since, would be to leave the corn to enemies whose increase would bid defiance to all other methods for their destruction. Sparrow clubs are a grand mistake, and, in this country, can never become an institution, because science has come upon the farm, and taught the farmers that the very nature of those birds is conservative of their crops. The times when both these and the rooks are

most troublesome are precisely those at which, owing to the plough not being at work and the insect tribes having executed their commission, their natural and favourite food is less plentiful than at other seasons of the year. The larks require looking after at wheat seed-time, being very destructive just as the young plants are pushing their stems above ground. But at other seasons of the year they devour immense numbers of the seeds of weeds, and insects. Being gregarious they leave the lands near the coasts in the early winter and congregate in the interior, where they infest the newly-sown fields, and commit sad havoc upon the springing wheats. They must, therefore, be looked after at that time of the year; while at others, when they are scattered about the country in pairs, they are far more beneficial than injurious.

But it is not the corn crops alone that are saved by the feathered tribe from the depredations of insects. The orchards and gardens are by them protected from the same enemies, which never fail to appear as soon as the summer has tempered the atmosphere. We have frequently known the small birds banished from the gardens under the charge of being there to devour the fruit, when the real object was the caterpillars and other insects which had made a raid upon the fruit-bushes and trees. The mischief done by the latter is incalculable, because the destruction of the foliage of a fruit-tree or bush involves that of the fruit. Nor are the woods themselves exempt from similar attacks; and if the woodpecker and the tree-creeper, with their strong beaks, drill holes in the bark of the trees, it is to extract the grub that lies concealed under it, and which would eat into the stem, and thus promote premature decay.

## THE ENGLISH SPARROW.

In the spring of 1866, four pairs of the English sparrow came to Union Square Park, and there built. Three pairs occupied the trees; one ejected a wren from her little house, the only bird-house then in the Square, and took possession; a fifth built in the ivy of Dr. Cheever's church, facing the Square. The industry of these little fellows in devouring the measuring worm—(so great a nuisance that most persons avoided passing through the Park, preferring to go around during their occupancy, and so numerous were they that they did not leave a leaf on any tree except the alanthus)—was such that boxes were provided on almost all the trees for them. They are very prolific, those hatched in the spring rearing a brood in the autumn and the old pair rearing four or five broods. In one year they increased from five pairs to a flock of seventy. The Park-keeper now estimates them at 600, making over seven-fold increase yearly. Last summer a reward of one dollar a head was offered for worms, but the birds had eaten the last one—they also eat moths, grasshoppers, and many other insects, and they are very fond of bees, which I consider a sinful appetite. Thus far these birds have benefited the city, and have extended to about 40 miles in every direction. The estimate that they destroy in Europe one-half million bushels of grain is probably correct; but how much, more or less, would the insects they devour destroy? The question is simply, which is the greater evil, worm or bird, and which most readily controlled? I have somewhere read that in one of the provinces of France a reward was offered for the heads of sparrows, owing to their depredations in the grain fields; in a few years the grain was more injured by the insects which these birds eat, than the birds ever consumed: it amounted to an almost total loss of the crop. The reward ceased, and in a few years they had an increase of birds, and a decrease of injurious insects. We can control the number of birds by protection, poison, or gun, and they can catch worms much faster than we can.—*Correspondent of Country Gentleman.*

## A WORD FOR THE CROWS.

That the rook may be fairly classed as one of the "pests of the farm" has long been a settled article of belief among farmers generally. At certain seasons the most careful watch is maintained against the supposed depredations of this much-abused bird; powder and shot are liberally employed in order to thin their numbers or frighten them from the locality, and the old clothes bag is rummaged to provide material for the purpose of dressing up "something like a man," which when placed in the field is expected to strike terror into the thievish breasts of the black-plumaged invaders.

It is of considerable importance to know whether such proceedings are justifiable or not; for it is quite possible that in condemning the rook to destruction we may be guilty of performing the not uncommon feat of jumping at a conclusion, and depriving ourselves of the services of a friend, while we imagine that we are getting rid of an enemy.

That farm crops frequently suffer severely from the attacks of various insects is a well-known fact, and it is equally well known that those insects form a description of food very acceptable to birds of various kinds. Were it not so, our fields, our gardens, woods, and orchards would soon become utterly destroyed, and the pleasant verdure which everywhere greets our eyes would be succeeded by sterility. This is the result in many parts of the world where vast numbers of locusts destroy every kind of vegetation, so that although "the land is as the garden of Eden before them," once they have passed, "behind them is a desolate wilderness." It would just be the same with us if the depredations of insects were not met by counter-checks which restrain the destruction caused by them within due limits, and of these checks birds are the most efficient. Very striking proof of this has been obtained in France, where small birds have been almost exterminated, the sporting proclivities of our Gallican neighbours being amply satisfied with such small fry as sparrows, larks, &c., and the result is that the growing crops have suffered to a serious extent from the attacks of insects, the damage done being perceptibly greater as the destruction of small birds has become more general and complete.

Now, although such an opinion may appear heterodox to some of our readers, we must declare in favour of the crow as the friend, and not as the enemy, of the farmer. No doubt, crows may become too numerous—but that may be easily provided for—and some damage may be done by those birds during seed-time and harvest, especially at the former season, when they are eager in the search for insects; but the damage is more than counterbalanced by their services as insect-destroyers. Speaking from experience gained in the immediate vicinity of extensive rookeries, we are prepared to say that the damage done was infinitesimal in amount compared with the benefits we derived from our noisy neighbours. Neither in our own case, nor in that of any of the adjoining farms, do we recollect of injury to growing crops from "grub" or similar pests, whilst those who were indefatigable in their exertions to restrain the insectivorous propensities of the rooks, by frightening them away, had the usual complaints to make of damaged crops. We have heard it alleged that crows are such cunning birds that they take good care not to commit depredations near home; but may not this arise from a scarcity of insect-food in the vicinity of the rookery, causing them to fly to a considerable distance in order to obtain that which their diligence has rendered scarce in the neighbourhood of their roosting and breeding places? On one occasion we remember seeing a large tract of outlying natural pasture literally black with crows, and being curious to know what was the cause of such an assemblage, we found, on proceeding to the spot, that the crows had pulled up the fog, which was plentiful in that place, evidently in search of small grubs, of which there were considerable numbers where the crows had not been at work. On leaving the place, the crows, which had only retired to a short distance while we were examining the ground, speedily returned and resumed their very useful labours. We took particular notice of that piece of ground during the season, and a decided improvement in the pasture was distinctly visible.

Scientific men who have studied the habits of birds and insects are unanimous in the testimony which they bear to the value of rooks as destroyers of noxious insects; and although science has not as yet made sufficient progress amongst farmers

to enable them fully to appreciate the benefits derived from the existence of a pest police-force like the crows, yet there are many practical men who do not require to be told that the crow is their friend, not their enemy. Notwithstanding all our investigations into the economy of the animal world, we know but little of the intimate relation of the various tribes of creatures to each other, and of the general plan of nature. All the classes of the animal kingdom have so close a connection with and dependence on each other, that the removal of any link in the chain might produce results of serious importance to man. Let us, therefore, be on our guard not to disturb the harmony which exists in nature, and before the farmer again puts the gun to his shoulder, let us ask him to acquaint himself a little with the natural history of insects, which we have no doubt will disabuse his mind of all his prejudices against the rooks.—*Irish Farmers' Gazette*.

## THE TRIAL OF THE ROOKS.

At a recent meeting of the "East Lothian Agricultural Club," Mr. DURIE, Barney mains, in speaking to a motion, of which he had given notice at last meeting, as to the desirability of diminishing the number of crows (rooks), said that he was certain that crows did an immense amount of damage to every farmer in the county. Mr. Scott Skirving and other friends of the crows said that they killed vermin. No doubt they did; but if they could put the amount of damage against the amount of good they did, the balance would be found to be on the wrong side for the farmer. He did not want their entire extirpation, but simply that they should be kept down, say to about half the number there were at present. He moved a resolution to the effect that the club was of opinion that the number of the crows should be diminished, and that the proprietors should be communicated with, in the hope of their taking means to destroy them in their districts.

The CHAIRMAN stated that many years ago an application was made to the Earl of Wemyss to allow persons to kill the crows in Anisfield Park. His lordship gave orders that every one should be killed, and 30,000 were supposed to have been destroyed in two days. From that day to this not a crow had been allowed to build in the Park. He did not think the crows were so plentiful in the county as they once were, but they were still too numerous.

Mr. MILL, Lgate, said he really thought that to a large extent the crows were the farmer's friends. They preserved the crops from grubs, and he thought it would be for their advantage if magpies and hawks were allowed to live, as they were many years ago, for the purpose of keeping down the small birds.

Mr. ELDER, Bearford, thought crows kept in a limited number would do good, but not in their present number. He knew that crows were fond of worms and grubs, but he also knew that they liked wheat, especially when coming through the ground. They might sow to the extent of a bushel of wheat less per acre but for the crows. If those who spoke in favour of the crows had visits from as many of them as he had, they would have a different opinion.

Mr. ELLIOT, Abbey Mains, seconded Mr. Durie's motion.

Mr. JENKINSON, Kidlaw, said that the crows "harried" a great number of the partridges' nests; otherwise he had never seen them do any harm.

Mr. SMITH, Whittingham, said his opinion was not confined to this district that the crows were very destructive. They took up, for instance, seed potatoes when they were planted. He had known them carry off these potatoes in their bills, and drop them when pursued. Whatever might be the natural food of the rooks, he thought it was evident that they had "a crap for all corn." Whatever magpies did, it was well known that rooks destroyed eggs to a large extent, so that he did not think it would require much persuasion to get gamekeepers to promote their views.

Mr. MILL said he never in his life saw crows attacking ripe grain; he had seen it many a time, however, destroyed by wood-pigeons. He never in his life saw crows on a stock.

Mr. BELFRAGE corroborated Mr. Smith's opinion as to the damage inflicted by crows in potato fields.

The CHAIRMAN said a celebrated naturalist had stated that

he would be obliged to any gentleman who could tell him that he ever shot a crow and found a grub in it, averring that they did not like the grubs.

Mr. PATON, Standingstone, said that he would much rather have partridges and small birds increased than the continuance of the present number of crows.

Mr. WYLLIE, Bolton, stated that the crows in seeking the grubs pulled out the plants. He thought that instead of looking to crows for the destruction of vermin they should apply the manures which would accomplish that object. He had seen thousands of crows sitting on stooks, and found many of them, which could not be taken in for some days on account of the wet, reduced to mere chaff.

Mr. Durie's resolution was then unanimously agreed to.

## WAR WITH THE COCKCHAFERS.

War! civil war in France, has begun. War with fire and—no, not with sword, nor Armstrong guns, nor needle rifles or revolvers, nor any other of those weapons of war which the nations of Europe are multiplying. The warfare here referred to leaves all modern conflicts in the shade as to the number of lives sacrificed, and contrasts strangely with these as to the character of the combatants and the weapons employed. The war is against an invading army of cockchafers (*hannetons*) with which the forests in certain of the départements of France have been infested; and so numerous have these plagues proved, that the authorities have determined to pay for their destruction, at the rate of so many francs per 100 kilogrammes (220lbs.), the persons employed being the women and children. So injurious had these insects become in 1866, that in the Département of the Seine the damage was estimated at 25 millions of francs (£1,000,000 sterling), and in 161 Communes it amounted to 2,632,700 fr. (£105,308 sterling). Not only were the forest trees of every kind, but principally the oaks, subject to their ravages, but the fruit trees and vegetables and even the cereal crops have been attacked and in many instances completely destroyed. In short, if the chafers be left undisturbed, they bid fair to be as great a scourge in Western Europe as the locust is in the East.

The cause assigned for the rather sudden appearance of these insects is the prohibition of the pasturing of swine in the forests, which was formerly free to those who resided in the vicinity. These animals, by their peculiar instinct and habits, were enabled to discover and turn out the white-worms, or grubs of the cockchafer, which are deposited in the soil, by which means their numbers were kept under. Their number is also ascribed in part to the dead leaves being left to decay on the ground, instead of the farmers and peasantry being allowed to collect and carry these away. By such means the surface of the ground is kept in a soft state, favourable to the deposition of the grub, or rather the eggs, of the cockchafer. Several of the *arrondissements* have, by their agricultural committees, offered prizes of silver and bronze medals, to be presented to those mayors who have been most active in promoting the destruction of the cockchafers. Some of the farmers are paying at the rate of 20c. or 2d. per kilogramme (of about 2lbs. 3 oz.), and one report from Barbaru states that up to the 4th of May 3,539 kilos. had been destroyed in four days. The number in each kilo. was 1,200, so that in this one case not less than 4,246,000 cockchafers were thus killed in four days. Had these lived they would have produced 30 eggs each, or 127,404,000 grubs, which in time would have become perfect beetles or cockchafers. There are only two hours in the morning in which this chase can be pursued, namely, just before sunrise. At that time the insects are sleeping, and being shaken from the

boughs of the trees, fall like lead to the ground, and are in that state gathered up and thrown into boiling water, and afterwards on the dunghill or manure-heap. The number given above as accounted for was in one parish, or commune, alone; it may, therefore, be conceived what must be the immense numbers in the whole of France, for it appears to be distributed into almost all of the Départements. We may state that the whole were taken by children and women, who thus earned, in English money, £27 10s. in four days. Similar means have been adopted in many other Départements, and with equal success.

There is no doubt that the prohibition of pasturing the swine in the forests by the 86th article of the *code forestier* has largely contributed to the increase of these insects. But in addition to this, the destruction of the small birds in France may have something also to do with it. The eggs of the cockchafer are deposited slightly under the surface if the soil is moist; and when hatched by the sun, the young worm buries itself deeper, and remains in the ground three years before it comes forth a perfect insect. It is not difficult to account for the immense numbers that have appeared in France this season, the weather having been peculiarly favourable to their production. In point of fact, naturalists and meteorologists have predicted their appearance in force this year, and have proved correct in their anticipations. The Imperial and Central Society of Horticulture of Paris has requested the Minister of Commerce and Agriculture to make the *hannetonage* (the destruction of the cockchafers) compulsory on the authorities of the different communes and départements, while a spontaneous movement by a great number of Councils-General have been instituted for raising the necessary funds to pay for their destruction. On the other hand, measures will be taken to reinstate with the occupiers of land in the neighbourhood of the forests the privilege of again feeding their swine in them, as one of the most obvious means of lessening the evil in future.

The United Kingdom has, happily, been exempt from this scourge for many years. In the year 1688, one-hundred-and-eighty years ago, so immense a migration of cockchafers took place in Ireland, that the air was darkened by it for a whole league, and it was difficult to travel along the road. Our exemption from them is probably owing to the destruction of the forests and the more frequent and perfect cultivation of the land. The white worms, or rather the eggs of the insect, are deposited in arable lands as well as in the woods, and when turned up by the plough are picked up by the crows, rooks, and other birds. The rooks, however, take the matter into their own hands in the case of the pasture lands, which are greatly liable to be undermined by the grubs. Every tuft of grass that has one under it is pulled up by the rooks. All the birds of prey are enemies to the insect tribes; but the rooks are the most domestic and numerous, and therefore are the most efficient. In the meantime the authorities are actively engaged in the employment in France of the means for destroying the cockchafer before they have deposited their eggs, which is a few days or hours after impregnation.

England is still far from being closed against an invasion. Certain favourable states of the atmosphere might bring a "cloud" of them, similar to that which appeared in Ireland. There is no calculating the power of insects for flight. The black turnip-fly, one of the most destructive insects on the farm, is apparently also one of the weakest on the wing; and yet, as is well known on the east coast, they come across the sea in clouds, and, exhausted by the effort, they lie in heaps upon the land adjoining the shore until they have recovered themselves. In this case, undoubtedly, they exercise an unerring in-

stinct, which serves them instead of actual knowledge, to avail themselves of a favourable wind to wait them to a country with which it is impossible for them to have any previous acquaintance.

## ABYSSINIA AND ENGLISH AGRICULTURE.

When the Roman Empire was in the zenith of its power Northern Africa was the chief source from whence Rome received her supplies of wheat and other agricultural products, and at the present time England imports no inconsiderable portion of her breadstuffs from the same quarter. Such being the case, the question just now naturally arises, Will our recent military visit to the capital of Abyssinia produce any effect in *Mark Lane*? The present Viceroy of Egypt has done, and is doing, much to stimulate agriculture throughout his dominions. Will this enterprise extend itself from the Mediterranean to the Indian Ocean along the Red Sea inland, as far as the tributaries of the Nile drain Eastern Africa, to which may be added the vast countries recently explored by Dr. Livingston? There are, within the large area of land thus imperfectly charted out, numerous tribes apparently emerging from a state of the rudest barbarity, who promise at no distant day to turn their industrious energies to the successful production of corn and cattle, flax and cotton, in greater abundance than they themselves require. Are we justified in looking to this vast area of the globe for increased supplies of such productions? And what influence will such supplies have upon English agriculture?

The latter question may at once be dismissed with a single stroke of the pen. Indeed, the English farmer (if we may for the sake of argument suppose an example) who apprehends any damage to his pockets from Abyssinia is something more than credulous. At the same time, although no overflowing rivalry in the English market is ever likely to come from this source, yet many eyes at the present time are turned to the agricultural capabilities of this hitherto much-neglected region of the globe.

The subject may briefly be considered under the following four heads—viz.: 1, Corn, including fruits of every kind, produced in Eastern and Southern Africa; 2, Cattle; 3, Flax, cotton, and other fibrous material for textile manufacture; and, 4, Timber, minerals, &c.

1. Of the first class of articles, Egypt may be taken as furnishing a parallel example for illustration over a large area of the country in question. Farther southwards, there must be added, these productions grow under a more vertical sun, some of which appear to be peculiar to Africa. On these latter, however, we do not intend to say anything; corn and pulse crops, with flaxseed and other seeds, linseed-cakes and cottonseed-cakes, being the articles chiefly interesting to the readers of the *Mark Lane Express*.

As yet there is not much prospect of permanent peace being established amongst the Nubian, Abyssinian, and Galla tribes; at the same time the recent campaign, from its having been attended with such singular success throughout, must produce a movement in this direction; so that the happy fruits of peace on a permanent basis may be reaped sooner in Abyssinia than some imagine. It will also, no doubt, give a fresh stimulus to agriculture in Egypt and in the whole country drained by the river Nile, for the inhabitants of the whole of this vast area of corn-and-pulse-producing land have become sensible to the potent efficacy of English gold. A thousand prejudices may erase from their minds the perseverance of the English soldier in cutting his way from the Red Sea to Magdala, but the sterling money left in the country amongst those engaged in the cultivation of the soil will tell its own silent tale long after our troops have returned to India and Britain. It may safely be concluded that, once show them that England is ready to relieve their markets of superfluous corn on advantageous terms, and many times the present quantity of corn produced will be grown.

The proposition is fully sanctioned by the experience of the British army in that part of the country through which it marched—a part not the most favourable to the growth of

corn; but the carrying out of the proposition into general practice is another and a totally different thing. What corn-merchant, for example, would, as yet, think of taking up his residence at any of the military stations of the British army, or market-towns visited by it, between Zoula and Magdala? But this question may be summarily disposed of; for the work, begin when it may, must proceed inwards from Egypt and the Red Sea by degrees, as Time and Progress lead the way. Were the chiefs of Shoa and Tigre to shake hands to-morrow, and peace to be established on a permanent basis, Egypt would not send us one quarter more wheat, the produce of next harvest, on that account. But were peace thus firmly laid on a solid foundation, more wheat would actually be grown in Abyssinia next year; and the surplus would eventually find its way, through Egypt, either by the Nile or Red Sea, to the English market; for the British corn trade has its emissaries throughout the whole of Egypt, accessible by the Nile and Red Sea; so that, were they to find supplies on easier terms farther up the country, or farther inland, the upshot may be taken for granted, however inconsiderate in magnitude supplies may be at the commencement. Compared with much of Russia, Turkey, and America, the prospects of trade are every whit as promising eventually.

Oil-producing seeds, and roots and feeding materials for cattle, are in great request in the English market; and articles of this kind could obviously be obtained in much greater abundance from the southern or upper provinces of Egypt than is now imported; and this trade could be extended to Abyssinia and to Southern Africa, via the Zambesi, in the course of time. There is no use in grumbling at the high price of oilcake, so long as the supply continues short of the demand; but if the imports from Eastern and Southern Africa can be increased—as doubtless they may—the commercial balance would turn in favour of the English farmer.

2. Although many of the tribes of Eastern and Southern Africa are pastoral in their habits, it is nevertheless problematical if they can ever send through Egypt either live fat stock or dead meat to the English market. At the same time it must be borne in mind that the country is more accessible than either Australia or South America, from both of which we now begin to receive supplies of preserved meat in tins. In the present transition state of things it would therefore be premature to speculate as to what the future may produce. A part of the country is infested with the "tsetse" fly of Dr. Livingstone. The tsaaltal, or Abyssinian spear fly of Bruce, very emphatically alluded to by the prophet Isaiah (xviii. 1): "Woe to the land shadowing with wings, which is beyond the rivers of Ethiopia;" a passage which has been translated, "Woe to the land of the tsaaltal fly, which is beyond the rivers of Ethiopia." So destructive is this fly to horned cattle, that they cannot be bred in the districts infested by it, so that were it to extend its ravages the consequences are not easily estimated. And, besides, it is very questionable if the quality of African meat would suit the taste of the English consumer. True, Australian and South American meat have each the peculiar flavour of the herbage eaten by the cattle, and with which the English taste promises soon to become familiar, and the same acquired taste would no doubt also relish in the course of time African meat.

3. Flax, cotton, and several fibrous products peculiar to South Africa, could no doubt be grown, and doubtless, in the course of time, will be grown in surplus abundance for the supply of the English market. The realization of this appears from the concurrent testimony of travellers to be only a work of time, so that it may be left in the hands of Progress for maturation. The growth of flax and cotton involves the production of oil-cakes, hence the connexion of this head with the first.

4. On timber and minerals little requires to be said. That the country abounds in both may be taken for granted; but with the march of improvement the probability is that the former will be required and consumed at home; while discovery has done comparatively nothing as yet to reveal the latter, which up to this date may be said to lie half-concealed in the bowels of the earth, only cropping out here and there in evidence of their existence.

The general conclusion from these desultory observations is, that results are more hopeful for Abyssinia and Eastern Africa than first thoughts may in many instances suggest, and that progress will, upon the whole, be in favour of English agriculture.

THEBES,

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

## MEETING AT LEICESTER.

## THE IMPLEMENT DEPARTMENT.

The display of machines in motion and of machines and implements at rest, to be met with, is indeed something very striking, and cannot fail to be, to the thinking mind, highly suggestive. The contrast which this for example, forces one to make, should not be lost sight of—the contrast between what agricultural engineering, taking this term in its widest acceptation, now is, and what but a decade or two it was. Scarcely a generation has passed away since agricultural machinery might have been generally, as it was literally in special districts, represented by the three primitive, or, as we should rather say, the three primary implements of culture—the plough, the harrow, and the roller; and when such limited motive powers as the limited work in which power was required by the farmer were represented by the oldest of all, manual labour; or, if a further extension were demanded, by the wind-mill and the water-wheel, both in their most simple stages of mechanical development. But the generation which has succeeded can now witness, at such a show, a remarkable exemplification of what the engineer and the mechanic have done—the one in inventing, the other in carrying out practically—to aid agriculture in all its departments, at once and equally useful in the field and in the fold—a condition of matter so extensively complete that any one thirty years ago could scarcely have believed it to be possible of realisation.

Another point which must strike even the most careless observer, in walking through the alleys and surveying the contents of the stands on either side of such an exhibition as that held this year, is the enormous influence which such a display of objects used in the practice of agriculture must have upon the vast body of visitors—an influence of the most beneficial kind; all the more, that in consequence of the custom which the Society has of visiting different districts in different years, it ultimately embraces within its limits the whole of England. It is not possible for even the most obtuse mind to come here and to go away without some useful impression having been made upon it; or the most prejudiced man taking home with him something which will overcome in some measure the erroneous notions as regards his daily practice, or touch stolid indifference and careless ignorance.

We find the crush and crowd most dense round the machines at work; here we find the eager faces and the still more eager inquiries of the interested. This was wonderfully exemplified at Leicester.

Let us take up first the novelties of the machinery-in-motion department; and here is the "rotary steam-engine," made by Mr. Robert Cowen, of Nottingham, the invention of Mr. Hall, and which attracted great attention from the simplicity of its general arrangement, and the ease and smoothness with which it worked even when run at very high velocities. In view of the disadvantages, or presumed disadvantages, attendant upon the ordinary reciprocating steam engine, with its somewhat complicated mechanical arrangements, the attention of a class of inventors, has through a long course of years been directed to the discovery of a form of steam engine in which these disadvantages and this complicated mechanical assemblage could be overcome. In the reciprocating engine, as is well known to

our readers, the motion of the piston made in one direction has to be stopped at the end of its stroke, and then moved in the opposite direction, at the end of the stroke of which it has again to be stopped, and again moved in a contrary direction. It is obvious, from these alternate movements and stoppages, which, although not observable in engines which run quickly, still exist, a loss of power, more or less in amount, results; for, to use a familiar mode of illustration, you set a train in motion, and as soon as you get it at full speed you stop it, not because you wish to stop it—on the contrary, you wish it to go on—but you have to stop it in order to get the next move in the train of its operations. Then, again, the great majority of operations are performed by the aid of circular motion, so that the alternate rectilinear motion of the piston of an ordinary steam engine has to be changed into a continuous circular one, and this again has to be re-changed into an alternate rectilinear movement to work the valves of the engine; so that, to meet all these exigencies of the mode of its operation, an ordinary steam engine, even in its simplest form, is so complicated, that we need scarcely wonder at the desire there is to introduce a steam motive in which the power is obtained directly by continuous circular motion, without the intervention of the mechanism we have above alluded to. But it is not to be supposed, whatever sanguine inventors may say, that a rotary engine, although theoretically, is practically better than a reciprocating one; on the contrary, the difficulties attendant upon the realization of a good rotary engine—as, for example, the keeping of the rubbing surfaces tight—are such that up to the present time no form of this class of engine has been able to compete with the reciprocating engine, which is so efficient and so economical in work and in the few demands it makes to keep it in repair, that it holds its own; and we must say that we believe that for a long time to come it will hold its own in the face of all competition. One may really buy gold too dear, and although one may have a rotary engine which is possessed of few working parts as compared with an ordinary reciprocating engine, it may in practice be found to be of such a delicate organization, so to say, that the cost of keeping it in repair is a formidable item; or it may be found that out of it you do not get anything like the full economy of the steam, which you would obtain in the ordinary engine. At the same time while saying all this, which under the circumstances of our duty it is right to say to our readers on the general subject, we are equally bound to say that the form of rotary engine, which we already alluded to as working at Leicester, struck us as being possessed of so many features of practical value, that we think it very possible it will have a "future of request" which has not been granted to many engines of its class. We shall now endeavour to describe the engine as clearly as can be done by words without drawings. The cylinder is placed horizontally at one end of the frame, and is provided with a steam-chest, which runs along the whole length of the cylinder at its upper part. In connection with the steam-chest, in the centre of its width or breadth, there is a chamber provided with an equilibrium cut-off valve, which regulates the admission of the steam to the steam-chest. The steam of the valve is passed through the stuffing-box of the chamber, and the lower end works in contact with a

circular cam, which slides upon the central axis or shaft of the engine, and is controlled by a horizontal governor. The motive power is obtained by the revolution of an eccentric piston, which is in fact a cylindrical roller round the interior of the main cylinder, the centre of the piston being the central axis of the engine. To maintain the roller or piston steam-tight, the part which is in contact with the interior surface of the cylinder is provided with spring-packing, and, further, with metallic springs at each end, these working against the turned surfaces of the end covers of the cylinder. The steam is made to move this roller or piston by a simple form of valve, which is raised into the space of the steam-chest above the cylinder, through the slot or spring made in the upper part of it and along its whole length, by the revolution of the piston or the roller itself, in rising from its lowest to its highest position in the cylinder; the return motion of the valve being effected by the pressure of the steam in the steam-chest upon its upper portion, which keeps it in contact with the piston as it moves round again to its lowest position. The valve is hollow, and the steam passes from it always on one side of the piston, or rather one-half of the roller's circumference; the exhaust steam passing out by a pipe on the other side of the cylinder. Diagrams shown us by the inventor indicate a very good distribution of the steam.

We now come to another novelty amongst the prime movers in the yard—namely, a hot-air engine. The obvious economy of the method of utilizing heat, by the direct application of it to air or other permanent gases, so as to get their expansive powers directly developed, has for long been recognised, and numerous inventors have endeavoured to realise it in practice. The difficulties however have been so great in the way of its realisation, that attempt after attempt has been made with the unfortunate result, as a rule, of failure more or less complete. Generally, the plans attempted had for aim the expanding of the air in a separate vessel or receptacle, the result being that, in consequence of the high temperature necessary, this vessel very rapidly decayed. Other difficulties moreover were met with, the chief of which was that of keeping the stuffing boxes and the piston tight, under the high temperature of the air used, and which also prevented the use of ordinary lubricating materials. Messrs. Edwards and Co., Oxford-street, London, who exhibited the form of hot-air engine above alluded to, claim to have overcome, by these arrangements, all these and other defects of hot-air engines hitherto introduced into practice; and to have succeeded in bringing out a highly-efficient form, and one which is very economical. A close inspection of this engine inclines us to believe that the inventors are, to a large extent, entitled to claim these advantages, and we now proceed briefly to explain by what means they secure them.

The first, and perhaps the most essential feature to be noticed, is the heat generation, which is combined directly with the air expander, or, in other words, the air is expanded by the direct action of the fuel in the generation; the air so expanded being forced into the generator or furnace by means of an air pump, which is worked by the engine itself. The cylinder is placed immediately above the furnace, and the air forced into it by the air pump gets heated by direct contact with the fuel, and rises up into the cylinder, pressing upon the piston and raising it. The piston is a hollow plunger, after the trunk engine principle, and the packing is placed around its upper circumference; which, being at some distance from the under part with which the hot air comes in contact, is comparatively of low temperature, and therefore enables the piston to be well lubricated. The furnace in which the fuel is consumed is lined with fire-clay, so that it is not subjected to the heat of the consuming fuel, and

therefore lasts a long time. When the engine is working, both the ash-pit door and that of the furnace are closed hermetically, the only air passing in being through the agency of the air pump. The engine can be started in a few minutes after the fuel is lighted, a few turns of the fly-wheel working the air-pump. The air-pump is placed at the back of the furnace and cylinder, and is worked by two rods passing down from and jointed to the cross-bar which connects the ends of two short working beams which are connected at their other extremities with the piston rod. The speed of the engine is regulated by dampers, which pass the air either *through* the burning mass of fuel in the furnace, or over the same, according to the amount required. These dampers are regulated through the agency of the governors, and are worked by cams from a small eccentric in the main driving shaft. One of the sources of economical working of this engine is the utilization of the gases which arise from the combustion of the fuel; these in all other forms introduced having been passed off into the chimney, the ordinary air alone when heated forming the source of motive power; but, in the engine now under notice, the permanent gases of the fuel are utilized as well as the ordinary air.

Not far from or rather close to the place where Edwards and Co.'s hot-air engine was working, a rival form of novel motive power was to be seen in operation—namely, the "Hugon Gas Engine." Although this is not so universally applicable to farming districts, inasmuch as on many farms gas is not obtainable, while the hot-air engine can be worked wherever fuel can be had; still, it will interest our readers to have before them a brief description of its peculiarities. In its general features this engine resembles closely that of a horizontal steam-engine, with, however, a greater size or bulk in proportion to its power, this arising from the space required in the cylinder to admit of the necessary space for the expansion arising from the explosion of the gas. The gas which works the engine is not passed into the cylinder in its pure or ordinary condition, as this would not give ignition the necessary explosive power; but is mixed with common air, in the proportion of nine parts of air to one of gas. In the first forms of this engine the gas was exploded in the cylinder by means of electricity; but this necessitated the use of so large a quantity of grease, that it seriously impeded the working of the piston, while in addition the complicated and delicate arrangements of the battery were such as to militate greatly against the introduction of the engine, as careful and accurate supervision is by no means generally met with in places where power is required. In the engine now used slide valves are used, which carry gas burners supplied at pressure with gas, and the gas is lighted and explosion caused by its coming in contact at the right time with a small jet of gas. This lighting jet, as it may be called, is blown out at each stroke of the engine, in consequence of the explosion; but it is immediately relighted by means of an ordinary jet, which is kept constantly burning outside. When the gases explode in the cylinder, a very fine spray of water is introduced into it, which, coming in contact with the heated surface of the cylinder (about 1200 deg. Fahrenheit being the temperature), is formed into steam, which at once reduces the heat, lubricates the working parts, and equalizes the pressure throughout the stroke. The valves work against orifices in the cylinder, so as to open or close them, bringing the burners to and from the orifices at certain intervals, thus admitting, intercepting, and regulating the supply of gas to the cylinders, and also permitting and shutting off the escape of gas therefrom after the explosion. When the gas is admitted to the cylinder through the induction part, the valve at the required moment brings the flame of the burner or lighting jet in contact with it; ignition and explosion take

place instantly, which presses upon and moves the piston along the cylinder, the induction part opening at the proper time allowing the remaining gases and steam to escape into the atmosphere. Nothing can exceed the great ease and simplicity with which this engine is set to and taken out of work, this being done as easily as the lighting of gas jets in a room. The engine works very smoothly with little or no noise; it is absolutely safe, and almost the only objection which can be made to it—for the peculiar positions which we think it is best adapted—is the price. A reduction of this would, we believe, be greatly to the interest of the makers.

Messrs. Ruston and Procter have one of their portable steam engines, with Chapman's eccentric, for securing a variable expansion. This is a very simple mode of giving an advantage of expansive working, so as to enable the engine to give off exactly the power required—a matter of the greatest importance; because, at times, the engine which is calculated to give off when required its full power, as in thrashing and the like, may at other times be required to give out only a portion of it, as in the case of straw and root cutting, &c. The forms of apparatus generally introduced by which all the advantages of expansive working have been sought to be obtained, have, as a rule, been complicated to a greater or lesser extent. In this form—the invention of Mr. Chapman—the parts are reduced to the minimum of simplicity, being in fact the same as in other engine valve gear, namely, one slide valve and one eccentric. How this simplicity is obtained may be seen from the following brief description, which will of necessity not be quite so clear as it would be if we had diagrams ready to illustrate it. To the crank shaft of the engine a circular plate or disc is keyed, and is concentric with the shaft—that is, has no eccentric motion, but revolves uniformly with it, as does the fly-wheel. This disc is provided with a slot or aperture passing from side to side. Close to the side of the disc, and hung or suspended, so to say, on the shaft, a crank axle is the eccentric for working the valve. The eccentric is connected with the disc by means of a bolt and nut; and this bolt can be secured at any point desired in the slot of the disc, and, according to its position in this, so will be the degree of eccentricity in the path of the eccentric, and by consequence the rate of travel of the valve rod and valve, and also the degree of expansion. The degree of expansion at any point of the slot is marked by graduated points on the side of the slot. This arrangement, like the curved, slotted link of an ordinary locomotive, is, like it, capable of being worked as a reversing gear, but the engine must be stopped before the reversing can be effected; whereas in the locomotive this is done without stopping the engine. This objection also holds in the case of altering the degree of expansion; but this is no great objection after all; the stoppage and adjustment take up very little time; while, once adjusted, the probability is that the degree of expansion obtained will be that required for the work of hours. Moreover, this apparatus is not costly—indeed, in the case of purchasers of the engines of Ruston, Procter, and Co., it is *costless*, as they apply it to all the engines they send out free of charge. In other instances we believe the charge is £15 only.

In the way of boiler novelties two examples were in the Show-yard; one of the Messrs. Howard's, of Bedford, the other that of Mr. R. Cowen, of Nottingham, on Fild's patent tube principle. The boiler of the Messrs. Howard we have already described in these columns; we therefore pass on to the boiler exhibited by Mr. Cowen, which, although in one sense is no novelty—having been worked by Mr. Field some three years ago—but in another is, for we believe this is the first time the prin-

ciple has been exemplified at any of the Royal Society meetings. The arrangements of the boilers depend upon the kind of boiler to which the principle is applied, but which is in all cases similar, and may be briefly described. The water space is provided with a number of tubes, these being closed at the lower ends and open at their upper ends to the water space, these upper extremities being some inches below the nominal level of the water in the boiler. These tubes are therefore filled entirely with water, and if left thus there would be little or no circulation of the water within their interiors; but to insure this circulation, each tube is provided with an internal tube, open at both ends, the lower end of which is carried down to within a short distance of the bottom of the outer tubes; while the upper end is carried some distance above the level of the upper end of the outer tube. The inner tube is suspended by means of fenders, and its upper end is finished off with an expanding funnel-shaped top, the wide end being uppermost. The arrangements here described is found in practice to bring about a remarkably quick circulation, and to reduce materially the tendency of the water to form deposits in the boiler or pipes.

#### AN ALPHABETICAL LIST OF THE EXHIBITORS OF AGRICULTURAL IMPLEMENTS, AT THE LEICESTER MEETING, in 1868.

AGRICULTURAL AND HORTICULTURAL ASSOCIATION, 29, Parliament-street, Westminster.—Variety of wire fence and hurdles, poultry court, palisade, wire netting, gates, tree-guards, cages, coops, archways, troughs, rollers, manure and linseed cakes, with samples of agricultural seed and artificial manure.

ALLCOCK, THOMAS, Ratcliff-on-Trent.—Cultivators, grubbers, and scarifiers; chaffcutters, horse hoes, horse rakes, one-horse manual-delivery reaper; back-delivery reaper, and improved carriage lifter.

ALLCHIN AND SON, Northampton.—Nine, eight, seven, and three horse portable steam engines; portable corn grinding mill, and set of six iron screwjacks.

ALWAY, WM., 37, Chapel-street, Pentonville, London.—Milk cooler, tin barrel churns, field churns, pails, and milk kettles.

AMIES, BARFORD, AND CO., Peterborough.—Presswheel rollers and clod crushers, water-ballast rollers, straw elevators, horse-gear works, corn and oilcake mills, steam cooking apparatus, portable boiler, stiles, hurdles, and garden seats.

APPLEBY BROTHERS, Emmerson-street, Southwark.—Steam lift and force pump; steam pump, donkey, or fire engines; lift pumps with rotary motion; other lift and force pumps, rock boring and tunnelling machines, and motor for working the diamond rock borer.

ARMSTRONG, JOHN, Penrith.—Swing and ridging ploughs, horse hoes, grubbers, drag and other harrows, and set of chain harrows with improved dividers.

ASHBY AND JEFFERY, Stamford.—Solid-axle haymakers, balance-lever steel-tooth horse rakes, patent wheel hand-rake, chaff cutters, oilcake breakers, turnip cutters, rotating and chain harrows, Tinkler's churn, one-horse gear work; three, four, six, and eight horse portable steam engines and combined thrashing machines; portable stone grinding mills, saw bench, crank shields, clod crushers, and field roll.

AVELING AND PORTER, Rochester.—Set of steam ploughing and cultivating apparatus, ten-horse winding engine; agricultural locomotive of ten-horse nominal, but will work up to forty horse; locomotive crane engine for roads; set of patent travelling rope parters.

ATSFORD, T. B., Walham-green, Fulham.—Village phaetons, Edinburgh dogcart, and canoe wagonette.

BAKER, JOHN, Wisbeach.—Corn-blowing, screening, and dressing machines, and patent rakes on Samuelson's reaper.

BAKER, THOMAS, Newbury.—Liquid manure and water carts, steerage horse-hoes, cultivator, two-horse gear, and liquid manure distributor.

BALL, GEORGE, Kettering.—Wrought-iron cultivators, iron ploughs, waggons, and one and two-horse carts.

BALL AND SON, Rothwell.—Collection of iron ploughs, scarifiers, rollers, harrows, carts, waggons, corn-drills, horse-rakes, chaff-cutters, horse-hoes, and two-horse gear.

BAMLETT, A. C., Thirsk.—Two-horse grass-mower, compound (combined P) reaper and mower, one-horse manual-delivery reaper, and stand for holding reaper-knives.

BARNARD, BISHOP, AND BARNARDS, Norwich.—Noiseless lawn-mowers without gear wheels, chains, or levers; ditto with gear wheels and improved side-tipping delivery; single and double cylinder garden-rollers, worm-cast distributor and loose-leaf gatherer, swing water-barrow, garden and park chains and folding-stools, tables, &c.; wire netting, cattle and poultry troughs and fountains, field-gates, and stable requisites and furniture.

BARROW AND SON, Borrowash, Derby.—Transplanting machine, for the removal of large trees.

BARROWS AND STEWART, Banbury.—Three and five-tined steam cultivators; four-wheeled windlass, iron anchor, three and two-wheel rope-porter, stationary ditto, snatch-block; double-cylinder portable steam-cultivating engine, eight-horse power; portable steam-thrashing engine, five-horse portable steam-engine, single-blast thrashing machine, thrashing and finishing machine with dressing apparatus, double-blower thrashing machine, corn-mill, conical burr-stone mill, lifting-jacks, endless driving bands, and waterproof covers.

BARTON, WILLIAM, Boston.—Cooking ranges and stoves, roasting-screens, hot closets, steam-kettles, and roasting-jack; also six improved tea-kettles.

BAYLISS, JONES, AND BAYLISS, Wolverhampton.—Field, entrance, and hand gates; cattle and other hurdles and fences, tree-guards, garden-rollers, heating and sack barrows, chain-harrows, vermin-proof rick-stands, carriage-jack, sheep-troughs, cisterns, pails, and skeps.

BEACH, JOSEPH, Dudley.—Farinaceous food for cattle, sheep, and pigs; and condiment for horses.

BRADSMOKE, THOMAS, Loughborough.—General-purpose wood and iron ploughs, cultivators, and chaffcutter.

BEARDS, THOMAS, Stowe Park, Bucks.—A two-furrow plough hung on an iron frame, mounted on four wheels.

BELCHER, GEE, AND CO., Gloucester.—Slate tanks and coolers for milk and whey; slate manger, cattle trough, and shelving; plain and enamelled face mantelpieces; and enamelled table top, inlaid with imitation marbles and flowers, with iron (bronze) stand, for the dining room.

BENTALL, E. H., Maldon.—Subsoil plough, broadshare and cultivator, angle iron harrows, chaffcutters, root pulpers, turnip cutters, root slicers, oilcake mills, corn and seed crushers, bean and oat kibblers, and horsegears.

BEVERLY IRON AND WAGON COMPANY, Beverly.—Clod crushers, plain field rollers, grass mowers and reapers, carts, waggons, liquid manure and water carts, wheels and axles, railways and trucks for farm purposes, root washers, pig troughs, bonedust and compound action mills.

BIGG, THOMAS, Great Dover-street, Borough.—Sheep-dipping apparatus on wheels, and with iron bar drainer.

BILLSON AND SONS, Leicester.—Collection of rick covers, wagon and cart covers; ropes for hoists, cranes, and pulley blocks; sacks made from jute and from hemp; wagon and cart ropes, fence netting, plough reins, halters, thatching cords, and clothes lines.

BLOW AND SON, 23, Commercial-street, Whitechapel, London.—Endless leather strap, indiarubber bands and hose, leather hose pipes, double strap for heavy machinery, strap butts and screws, donkey pumps, oat bruisers, cottage range, and corn mill.

BLOXSON, JOHN MARTIN, Gilmorton, Leicestershire.—Six horse portable and 2½ horse stationary steam engines, double-blast combined thrasher, circular-saw bench, chaffcutter, six-row steerable corn drill, and one-horse reaper.

BOBY, ROBERT, Bury St. Edmunds.—Iron and wood-beam ploughs, plough-wheels, ribbed rollers, barley-rolls, haymakers, horse rakes, corn screens, barley haveler, corn dressers, chaff sifter, horse power, and malt plough.

BOYNALL, HEMPESTED, AND CO., Grantham.—Eight-horse portable engine, treble blower, finishing thrashing-machines, straw elevators, chain corn-drills, horse hoe and turnip thinner, weighing machine, cylindrical bearings, screw jacks, chilled plough-shares, hay forks, and portable grinding mill on travelling wheels.

BOULTON, W. S., Norwich.—Swing water barrow and liquid manure carts, garden engines, portable pump and suction, garden chairs, and wire netting.

BOYALL, R. J., Grantham.—Stanhope phaeton wagonette with reversible seat, village phaeton, Alexandra car, Dagmar car, and light medium-sized brougham.

BRADFORD AND CO., 63, Fleet-street, London.—Vowel washing, wringing, and mangling machines, drying closets, linen press, mid-feather and counter-current churns, portable boilers, riddling apparatus, and "Eclipse" cinder sifter.

BRAGGINS, JAMES, Banbury.—Park, entrance, field, and other gates, iron work and posts complete.

BRAINSBY, THOMAS, Peterborough.—Very light Oxford dog-cart, village phaeton for six persons, Taunton dog-cart on eighteen-spoke hickory wheels shod with steel, and Maxwell car to carry two or four persons.

BRANFORD AND SON, March.—Draining, splitting, and ridging ploughs; diamond, Tweedside, and revolving horse-hoes; barley haveler, "international" washing, wringing, and mangling machines.

BROUGHTON, J. AND J., Leicester.—Lever washing, wringing, and mangling machines combined.

BROWN, BENJAMIN, 39, Charlotte-street, Blackfriars Road.—Samples of improved steel spring lever oil-feeders, needle lubricators, belt fasteners, vent-peg on hydraulic principles, glass lantern for stables, and patent egg-testers.

BROWN LAWRENCE, Leicester.—Lancewood shafts, brougham fronts, wheel rims, phaeton wings, carriage fulcrums, bottom sides for basket phaeton, and ash cart shafts.

BROWN AND LOCK, Shrewsbury.—Eight and nine-horse "Economic" portable steam engines, and two-horse gear works.

BROWN AND MAY, Devizes.—Eight, six, and 2½-horse portable steam engines; combined thrashing, winnowing and riddling machine.

BURGESS AND KEY, 96, Newgate-street, London.—Grass-mowers, combined reapers and mowers, sheaf and swathe delivery reapers, sausage machine, churn, corn-bin, and garden-seat.

BURNEY AND CO., Mill Wall, London.—Wrought-iron cisterns, water-cart bodies, tanks, drinking pans, cattle-troughs, and corn-bins.

CAMBRIDGE AND CO., Bristol.—Rollers, chain harrows, excelsior tine harrows, land pressers, one-horse gears with intermediate motion, two-horse gear and thrashing machine horse rake, and turnip cutters.

CANADIAN WASHING MACHINE AND AGRICULTURAL IMPLEMENT COMPANY, Worcester.—Sets of "Paragon" harrows, washing, wringing, and mangling machines, clotheshorses, and a double-action steam power washing machine.

CARR, THOMAS, Richmond Road, Montpelier, Bristol.—Pulverizing disintegrator, for artificial manure works.

CARSON AND SONS, Belle Sauvage Yard, Ludgate Hill, London.—Samples of the "original" anti-corrosive paint, pure linseed oil, drying oil, turpentine, varnishes, paint brushes, pots, &c.

CARSON AND TOONE, Warminster.—Chaff and turnip cutters, horsehoes, horsegear for driving chaff cutters, &c., oilcake crushers, garden roller, and assortment of cheese presses.

CARTER AND CO., 237, High Holborn, London.—Samples and specimens of wheat, barley, and oats; samples of mixed grasses, and of agricultural and garden seeds, and collection of ornamental terra cotta pots, vases, &c.

CHAPMAN, WM., Apethorpe, Northamptonshire.—Two-horse wagon, two and one-horse carts, and light spring lorry or dray.

CHEAVIN, GEO, Boston.—Stone and iron self-cleaning rapid water filters "for removing lime and other impurities out of any kind of water."

CHURCHILL, CHARLES, 16, Lawrence Pountney Lane, London.—Anti-freezing American pumps; champion, pitcher-spout, and deep well pumps; hydraulic ram, hand, rotary, and double-discharge force pumps with air chamber, hay and manure forks, grindstone, American corn-sheller, parallel vice, Coe's screw wrench, broad-cast seed sower, pivot boring machine, axes, &c.

CLARK, JAMES, Lincoln.—Flat rollers, dressers, corn drills, turnip drill, chain harrows, shaking screen, and assortment of malleable castings.

CLARKE AND SON, Brackley.—Complete set of draining tools, adjustable garden and other scythes with tubular iron sheaths.

CLAY, CHARLES, Wakefield.—Cultivators, chain harrows, horse-hoes, and grubbers.

CLAYTON, SHUTTLEWORTH, AND CO., Lincoln.—Ten-horse power, double-cylinder portable steam-engine, eight and six-horse single-cylinder portable engines, and ten-horse horizontal fixed engine; double-blast finishing thrashing-machines, portable straw-elevator, sack-lifting barrows, set of adjusting blocks for choking the wheels of an engine or thrashing-machine, revolving liquid manure and drop drill for turnips and other seeds, and self-acting circular-saw bench.

COLEMAN AND LOVE, Northampton.—Lever cultivators, horse hoes, cultivating harrows, bin and trough with hay-rack, horse hoes, and oil-cake breaker.

COLEMAN AND MORTON, Chelmsford.—Yarrow and Hilditch's steam-cultivating apparatus, three-furrow steam-plough, subsoil plough, variety of cultivators, clod-crusher, Hanson's potato-digger, manure and water carts, corn screens, oil-cake cutters, horse gears, rope porters, and samples of shares.

COOCH, JOHN, Harlestone.—Corn dressers, and small seed apparatus.

COOKE AND CO., Lincoln.—Wood and iron swing and wheel ploughs, drag, harrows, waggon, one and two horse carts.

CORBETT, THOMAS, Shrewsbury.—“Eclipse” combined blowing, winnowing, and screening machines, and “Excelsior” self-cleaning corn screen.

CORBETT AND SON, Wellington, Salop.—Cultivator, four horse portable steam engine, root pulpers, mills for feeding purposes and for breaking and grinding oilcake, hand mill for grain, chaff cutter for power, turnip slicer and scuffer.

CORCORAN AND CO., 48, Mark Lane, London.—Samples of French runner and bed millstones, Golay's new patent diamond millstone dressing machines, wheat-cleaning and flour dressing machines, aspirator with riddles, weighing machines, mahogany stone staff, jack stick, sack trucks, mill bills and handles, flour brushes, mill brooms, flour scoops, smut wire, malt-kiln floor, shovels, measures, chronometer, sample-corn receiver, woven wire, broadcast seed-sower; gut, leather, gutta percha, and indiarubber driving bands; oilcans, pulley blocks, mineral sieve, and deckle strap.

CORT AND PAUL, Leicester.—Cooking apparatus and boiler ranges, Rumford stove, oven and sham, variety of other stoves, flower guards, stable furniture, pig and poultry troughs, hurdles, fences, gates, and kitchen requisites.

COTTAM AND CO., 2, Winsley-street, London, W.—Large assortment of stable furniture, cattle troughs, corn bins, and dog troughs.

COULTAS, JOHN, Grantham.—Clod crushers, general purpose and manure drills, artificial manure distributors, corn and seed drills, carriage steerage, horse hoe, horse rake, and two-horse self-raking reaper.

COWEN, G. R., Nottingham.—Eight-horse power horizontal engine, eight-horse rotary engine, two-horse ditto, and ten-horse boiler with patent tubes.

COX, WM. PENN, Leicester.—Newspapers.

CRANSTON, JAMES, Birmingham.—Patent conservatory, highly commended by the Royal Horticultural Society.

CROSSKILL AND SONS, Beverley.—Clod crushers, field rollers, carts, waggons, liquid manure carts, portable pump, cart wheels and axles, Archimedian root washers, portable farm railway, trucks, and turntable, three-horse and self-acting sheaf-delivery reapers, improved single-roller bone mill.

DAVIS, ALFRED A., Royal Polytechnic, London.—Lactometers or milk tests; mechanical and scientific gyroscopes, and model steam traction engines.

DAY AND SONS, Shavington, near Crewe.—Driffield oils, drenches and draughts for cattle, horse powders, and medicine hests.

DAY, SON, AND HEWITT, 22, Dorset-street, London.—Stock-breeder's complete medicine chest, with “Key to Farriery,” various drenches, condition balls, gaseodyne, and sulphuretted extract; lecture on sheep, and essay on calves.

DEATH AND ELLWOOD, Leicester.—Eight-horse and 1½-horse fixed steam engines, steam pumps, two and four-horse works, circular-saw bench, bolt-head and nut-shaping machine, fourteen-inch centre screw-cutting lathe, 10½ and 6½ ditto, and drilling machine.

DELL, WM. R., 72, Mark Lane, London.—Four-horse power vertical fixed engine, wheat cleaner and separator for flour mills; “Paris Exhibition,” “Eclipse,” “Unique,” and “Paragon” smut machines; Golay's diamond millstone dressing machine; French burr runners and bedstones, eye for stone for grinding cement, portable crane for lifting millstones, swivel carriage, iron worm creeper, lifting jacks, straps, pulley blocks, weighing machines, and sack lifter.

DENTON, HENRY, Wolverhampton.—Chain harrows, horse gear, rib roller, slide valve for steam engine, and stand for reaping machine receiver.

DIXON, ADAM, 11, Adam-street, Adelphi, London.—Thirty steam and vacuum gauges, eight double diaphragm steam gauges, seven single ditto, four glass or water gauges.

DODGE, GEORGE P., 79, Upper Thames-street, London.—Assortment of vulcanized indiarubber machine bands, suction hose, tubing, waterproof cover, gutta-percha driving band, indiarubber bucket and deckle straps, ditching and maling boots, tarpaulin, and asphalt roofing felt.

DRIFFIELD AND EAST RIDING PURE LINSEED CAKE COMPANY, Great Driffield.—Pure linseedcake manufactured by the newly patented process.

DUFFIELD, HENRY, 60, William-street, Regents Park, London.—Variety of butter prints for farm and private houses, boxwood butter beaters and slicers, butter curlers, boards, trainers, skimmers, ladders, and specimens of fancy woodware for ladies' use.

EASTWOOD, JOHN, Blackburn.—Two to thirty-gallon compound action churn, the latter with pulleys.

EATON, JOHN, Thrapston.—Rack bar, lever, and screw jacks; sack elevator, and circular sheep cribs.

ELLIS AND EVERARD, Leicester.—Quantity of Markfield granite blocks as quarried, granite paving setts, curbing, and small-sized stones; quantity of blocks of stone from Bardon Hill; specimens of coal and limestone; linseedcake, cottonseed cake, manures, and articles used in adulterating them.

ELLIS AND SONS, Leicester.—Samples of blue lime in stone, burnt in shell, and ground; gate posts in Groby slate, salt troughs for cattle, milk slates, window sills, roofing slates, kerbing, and sink stone.

EVANS, JAMES, Liverpool.—“Viceroy” handsome osh, “Alexandra” drag, “Stanhope” phaeton, and “Dennet” gig.

EVANS AND STAFFORD, Leicester.—Specimens of American cheese made in the state of New York, weighing from 300 to 1,135 lbs. each cheese.

FISKEN, WM., Stamfordham.—Set of two-anchor windlasses for steam culture, and steam boiler “of immense strength and heating surface.”

FOSTER AND CO., Lincoln.—Eight and ten horse portable steam engines, combined portable finishing thrashing machine, fixed corn mill, 24 horse fixed steam engine, portable circular-saw and boring bench.

FOWLER AND CO., 71, Cornhill, London.—Twenty-horse power double set of steam ploughing machinery, eight and ten-horse hauling apparatus for steam culture, balance ploughs, cultivators for light or heavy sand [land F], sets of harrows, subsoil ploughs, Norwegian harrows, seed drill with harrows, revolving pulverizers, balance five-tine bevel beam cultivators; steam drain digger and mole plough; van to carry the spare parts of the steam plough, fitted with six beds for the men; traction waggon, water carts, horse ploughs, and traction engine.

FOX AND SON, Doncaster.—Assortment of jute, flax, and hemp sacks and bags, wool sheets, canvas, beddings, ticks, paddings, and sackings.

FRER AND CO., Rothley, Leicestershire.—Grain and seed dibbling machines, fitted with dibbles at the periphery of four, five, and six hollow iron serrated wheels.

GARDNER, WM., Gloucester.—French runner millstones and bedstones, cast-iron millstone prover, flour bolter, mill staff, pick, millbill handles, machine wire and brushes.

GARRETT AND SONS, Saxmundham.—Six and ten-horse portable engines, agricultural self-moving steam engine of eight-horse power, combined thrashing and dressing machines, French burr stone grinding mill; corn, seed, and manure drills; horse hoes, artificial manure distributors, fore-carriage drill steerages, straw elevators, corn dressing machine, hay and corn rick ventilators, patent grain ventilators.

GATWOOD AGRICULTURAL IMPLEMENT AND MACHINE CO., King's Lynn.—Eight-horse power patent combined locomotive thrashing and dressing machine.

GIBBONS, PHILIP AND H. P., Wantage. — Seven-horse power portable steam engine, and portable combined finishing and thrashing machine.

GIBBS (THOMAS) AND CO., corner of Half-moon-street, Piccadilly. — Collection of dried specimens of natural grasses used in forming permanent meadows; specimens of English and foreign wheats, barleys, and oats in the ear; samples of permanent and other grass seeds, and clover, mangold wurtzel, turnip, and carrot seed; agricultural roots, and growing specimens of agricultural seeds.

GILBERT, JOSEPH, Evesham. — Combined thrashing machine, fitted with Clayton and Shuttleworth's patent beaters, and Coulson's spring hangers.

GOODALL, HENRY, Derby. — Domestic kneading machine, dash churn, and butter powder "for extracting all impurities from the cream."

GOSS AND SON, Plymouth. — Zinc stencil plate letters for marking millers' sacks, branding figures for marking sheep's wool with paint, letters for branding brewers' casks and bullocks' horns and hoofs, moulders' letters for ironfounders and engineers, silver electrofaced types and blocks, and specimens of persons' names cut out of solid steel.

GOUCHER, JOHN, Workop. — Collection of drum beater plates, model of a thrashing machine, and working model of a swimming machine consisting of wings secured to a central back rib, to be worked by the hands and feet.

GOWER AND SON, Market Drayton. — Corn and seed drills, two-furrow drill presser, manure drills for ridge and flat, ridge drills for turnips and mangold, twenty-three coulter drill for clover and rye grass, Plymouth prize medal broadcast machine, patching drills, and horsehoe and scuffler.

GRANT, JOHN, Love-lane, Southwark. — Portable railway without cross sleepers, ballast wagon, and portable turn-table.

GRANTHAM, CHARLES, Peterborough. — Dressing and blowing machine with elevators, and combined dressing and blowing machine.

GREEN AND SONS, 54, Blackfriars-road, London. — Four-horse power steam-engine, lawn-mowing machines, garden rollers, mincing sausage machine, and Rotterdam chairs.

GREEN, JOHN, Newtown, Worcester. — Digging, pulverising, or cultivating plough; rollers, clod crushers, harrows, horse-rake, and scarifier.

GRIFFIN, MORRIS, AND GRIFFIN, Wolverhampton. — Sample bags of manure; corn, flour, and malt sacks; rick sheet, cart and wagon covers, and sheet for portable engines and thrashing machines.

GROVER AND BAKER, 150, Regent-street, London. — Assortment of double-lock-stitch sewing machines.

HANCOCK, F., Dudley. — Machines for making butter and pulping potatoes; also for pressing juices from fruit.

HANCOCK, JAS. L., Sutton Coldfield. — Haymakers, butter purifiers, tincture presses, spring and wool mattresses, and newly-improved carriage wheel.

HANCOCK AND FODEN, Sandbach. — Combined reaper and mower with endless chain of double cutters and double-fingered bar, and six-horse horizontal fixed steam engine.

HANDLEY, R. G., Birmingham. — French runner millstones and bedstones, mahogany millstone staff, box mill chisels and handles, needle lubricators, Derby Peak grey runner millstone, metal prover, millstone-face gauge, spiral beater for dressing mill, machine wire and brushes.

HARDON, EDWIN, Strangeways, Manchester. — Royal patent cake and "original" condimental food.

HARE AND CO., 31, Essex-street, Strand. — Illustrations of implements, engines, and machines; list of British and foreign prize medals.

HARRATT, CHARLES, Nottingham. — Patent steam spade, "urged into rotary motion by a ten-inch steam cylinder, without crank or flywheel."

HARRIS, JOHN, 53, Long-lane, Bermondsey. — Moveable letters and brands "to prevent oxydization of marking inks," sheep and sack marks, stencil plates, steel letters, and permanent marking inks.

HARRISON, THOMAS, Lincoln. — General purpose, liquid manure, ridge, cup corn, and barrel corn drills, and small seed distributor.

HARRISON AND BROTHER, Leicester Forest East. — Four-and-a-half inch wagon, and four-inch cart.

HARRISON AND SON, Leicester. — Collection of agricultural and other seeds, roots, plants, flowers, coloured plates, &c.

HART, DAVID, 244, Whitechapel-road, London. — Fixed and portable machines for weighing bullocks, sheep, pigs, wool, leather, hides, roots, goods in sacks, and for general purposes.

HARWOOD, WM., 36, King William-street, London Bridge. — Sheep scales, scythe sharpener, edge tool and table cutlery sharpener; step chair for gardens, library, halls, &c.; atmospheric churn, carpet sweeper, and small goods for various domestic purposes.

HAWKES, SPENCER, AND CO., Tiverton. — Eight, eleven, and thirteen-row patent chain corn drill.

HAYES, EDWARD, Stony Stratford. — Ten-horse portable steam engine, patent self-acting windlass, combined cultivator, iron anchors, snatch blocks, rollers, levers, crow bars, and steel rope.

HAYES AND SON, Stamford. — Waggons, carts, lorries, van, private omnibus, phaeton, and seaside sociable.

HAYS AND SON, Elton, Hunts. — New patented straw elevator, to work at any angle, and with patent vibrating boxes, to secure the waste corn that escapes the combined shaker.

HAYNES AND SONS, 220, Edgeware-road, London. — Hydronette for watering gardens, greenhouses, and conservatories.

HAYWARD, TYLER, AND CO., 84, Upper Whitecross-street, London. — Horizontal high pressure steam engines of  $\frac{1}{2}$ -horse power, rotary tank and other pumps, horse wheel for high speeds, lubricator, carbonator, garden engines, stock valve, hydrant, and stand pipe for fire mains.

HAYWOOD, J. AND G., Derby. — Sets of draining tools, chaffcutters, two-horse gears, cheese presses, curd mills, grass mowers, field rollers, haymakers, horse rakes, carts, ploughs, harrows, cultivators, scarifiers, corn dressers, drills, mills, root pulpers, turnip cutters, harrows, mangles, vases and pedestals, washing machines, and a variety of garden requisites and domestic utensils.

HEADLY AND SON, Cambridge. — Nine and seven-tine cultivators, water cart, drag rake, cattle troughs, mangers, reapers, gapping drills, garden pumps, corn bin, school desk and form combined, weather vane, garden chairs, and flower stands.

HENTON AND SON, 268, Westminster Bridge Road, London. — Elastic side and other saddles, and Melton saddle stands.

HILL AND SMITH, Brierley. — Skim plough, cultivator, rollers, harrows, horse hoes, chaff cutters, racks and troughs, barrows, varnish, forge, work-bench, garden seats, tree guards, rollers, rick stands, gates, hurdles, fences, netting, stable fittings, sheds, and dog kennel.

HILL, WM., 57, Aylestone-street, Leicester. — Disc washing, wringing, and mangling machines; single and double wood and wicker perambulators and farmer's benzoline lantern.

HIND, H., Nottingham. — Self-acting double-gear slide and screw-cutting treadle lathe, four-jaw chuck, vertical bench drilling machine, strong iron saw bench, double-purchase crab, punching bear, traversing lifting-jack, ratchet brace, stocks, dies, drop-through taps, and stops; jump-jointed brewing pan, belting, shafting, and pulleys.

HITCHCOCK, THOS., B., Bury St. Edmunds. — Leather machine-driving bands, convex thrashing machine driving pulley, adhesive composition for leather bands, and white leather thongs.

HITHERLEY, THOMAS, Thrusington. — An assortment of iron and wood ploughs.

HOBBS, PHILIP, Basinstoke. — Three and four-beamed harrows with whippetrees, corn, bean, and oilcake mills, sack cart and elevators, screw cribs, wheelbarrows, liquid manure pump, and corn screen.

HOLMES AND SONS, Norwich. — Rotary harrow, land roller, eight and seven-horse portable steam engines, thrashing machines, straw elevators, saw tables, clover and trefoil seed sheller, corn and seed drills, fore-carriage steerage, seed and manure drills, roller ridge drill, handbarrow drills, and corn dresser.

HOLTOAK AND SONS, Crosby, Leicestershire. — An assortment of best picked wood drag rakes.

HOPPE, WM. ASH, Wellingborough. — Cattle food condiment.

HORNBY AND SONS, Grantham. — Wrought iron ploughs, eight and ten-horse portable steam engines, combined thrashing machines, corn screens, turnip slicers and root pulpers, corn and seed drills, horsehoes, "Paragon" mowers and reapers, "Premier," "Governor," and other semi-manual, back delivery, swathe delivery, and self-acting reapers; washing,

wringing, and mangling machines, and indiarubber clothes wringer.

HOWARD, J. AND F., Bedford.—Steam-cultivating machinery, double-action steam cultivators, traction waggons, ploughs, harrows, clodcrushers, snatchbox slings, rope-porters, liquid manure and water carts; ridging, subsoiling, digging, paring, and potato-raising bodies; iron colonial, swing, and other ploughs; plough sledges, dynamometer, harrows, double-action haymakers, horsesakes, reapers and mowers, and twenty-horse patent safety steam boiler and super-heater.

HOWES AND SONS, Norwich.—Norfolk shooting carts, Norwich car, Norwich cart, and basket car.

HOWCUTT AND BARWELL, Leicester.—Samples of linseed and cottonseed cakes, palm-nut meal, agricultural seeds, and natural grasses of known good variety.

HUDSPITH, WM., Haltwhistle.—A miscellaneous assortment of specifically-named fern and floral "arborets."

HUMPHRIES, EDWARD, Pershore.—Combined double and single-blast thrashing, shaking, riddling, winnowing, elevating, finishing, and sacking machines; a Clayton and Shuttleworth's ordinary portable steam engine of seven-horse power.

HUNT, REUBEN, Earl's Colne.—Steam-power clover and trefoil seed drawer, horse-gear with intermediate motion, corn and seed dressers, oilcake breakers and root pulpers, turnip cutters, and root graters, steerable horsehoe and horse rake.

HUNT AND PICKERING, Leicester.—A collection of iron and wood beam ploughs; stubble-paring, subsoil, and ridging ploughs; sledge; cultivators, grubbers, and scarifiers, self-lubricating, field rollers, cylindrical land pressers, three and four beamed iron harrows, spike and chain harrows, whippertrees; seed, turnip, mangold, manure, pea, bean, steerable, and patching drills; horse hoes, mowers and reapers, knife bar, horse rake, oilcake breaker, roller corn crushers, chaff cutters, root pulpers, cheese presses, grindstones, horse-powers, rick stands, rakes, barrows, carts, sheep troughs, churns, steam engines, garden requisites, domestic utensils, &c.

HYDES, THOS., Sheffield.—Wrought-iron braced field, entrance, and hand gates; tree guards, deer, sheep, cattle, and ox hurdles, continuous fence, wire netting, garden seats, trucks, safes, coops, arches, verandahs, corn bins, water barrow, vermin-proof rick stands, unclimbable and ornamental hurdles, and portable tent for picnics.

ISON, J. AND E., Ashby-de-la-Zouche.—Two-horse combined reaper and mower (Bamlett's), Hornsby's reaper, Samuelson's self-acting side-delivery reaper, noiseless lawn mowers, sheep racks and troughs, garden fountains, vases and pedestals, garden seats, hat and umbrella stands, bronzed tables, flower-pot stands, Wheeler Wilson's lockstitch sewing machines, and Davenport ditto.

JACKSON AND FOSTER, Leicester.—Newspapers.

JAMES, ISAAC, Cheltenham.—Liquid manure distributors and pumps, flexible rubber suction pipe, wheel clod-crusher; field roller for turf, corn, or clods, water carts, gapping drills, mortar tempering machine, American clothes drier.

JEFFS AND STEVENSON, Liddington, Rutlandshire.—Two 24-teeth and two 26-teeth hayrakes; also two harvest rakes of 16 and 17 teeth.

JESSOP, J., Leicester.—Double-cylinder locomotive steam crane, with radiating derrick and travelling motion.

JOHNSON, T., Leicester.—Specimens of photographs taken from implements, machinery, ironfoundry, and carving.

JOHNSON, W. F., Leicester.—Variety of ploughs, cultivators, rollers, harrows, whippertrees, horsehoes, drills, manure carts and pumps, reapers and mowers, horseakes, drag rakes, winnowers, carts, oilcake breakers, gear work, chaffcutters, corncrushers, turnip cutters, root pulpers, lever cheese presses, curd-breaker, barrel churns, portable field-vices, lawn mowers, washing &c. machines, sheep troughs, Chinese gong, corn bins, hat &c. stands, bronzed hall-tables, whatnots, cast-iron wall-trophy, door-porter, sets of croquet, garden seats, and other fittings, ceiling ornaments, ice safes, marble chimney pieces, stoves, fenders, stack and wagon covers, resisting safes, rollers, and combined garden seat and roller.

JONES, J. M., Gloucester.—Composition for waterproofing, softening, and preserving all kinds of leather; specific for footrot in sheep, and cattle oils.

KEARSELY, H. AND G., Ripon.—Two-horse grass mowers, one-horse reaper, and combined reaper and mower, stand to hold reaping machine knives, two-rowed turnip and mangold drill.

KEITES AND SONS, Leicester.—Light sociable cart, White-chapel cart for four or less persons, and cottage pony gig.

KINDER, HENRY, Leicester.—Landau with skeleton boot, circular-fronted brougham, wagonette, and dog cart.

KINSEY, H., Nottingham.—Combined vertical engines and boilers, twelve and four-horse horizontal tanks and foundation engines, saw bench, steam pump, flour mill, and chaff cutter.

KITZMER, BENJ., Fulstow, Lincolnshire.—Six combined corn dressing and blowing machines, with two loose hoppers, for either dressing or blowing.

KNIGHT AND CO., 42, Hanway-street, Oxford-street, London.—The "Wonder" and "Surprise" sewing machines; also self-acting and ventilating nose or feed bag for horses.

LAEKWORTHY AND CO., Worcester.—"Excelsior" iron wheel and swing ploughs, iron scuffle drag harrows, and three and four-beam iron harrows.

LAUNDON AND CO., Leicester.—Chemical manures for roots, corn, grass, &c.

LAW AND SONS, Leicester.—Three to ten-horse power horizontal engines, 2½-horse power portable multibular boiler, one-horse power works, clay mill, steam hosiery press, seven and eight-row Leicestershire, corn and seed drills, two-horse vertical engine and boiler combined, saw-table, garden rollers, pig troughs, mangers, cooking ranges, hay rack, and cottage pump.

LE BUTT, JOSIAH, Bury St. Edmunds.—Self-acting seed drills, double-action haymakers, sharpening rests, "ever-lasting" malt screens, and Abercorn chairs.

LEE AND CO., Leicester.—Eight-horse power steam engines portable and fixed; vertical engines of five and 3½-horse power.

LEWIS, WILLIAM, Shrewsbury.—General purpose and light-land ploughs, lever cultivators, clod crushers and press-wheel rollers, cast iron land rolls, general purpose and chain harrows, two-coulter ridge drill for turnips, turnip hoes, "Governor" self-raking reaper, "Paragon" combined mower and reaper, and "Premier" one-horse iron-frame reaper, universal harvester, cheese press, cast-iron roller bracket, improved holder for sharpening sickles, mowers and reapers.

LYON, A., 22, Windmill-street, Finsbury.—Several mincing and sausage machines, including a machine for the dinner-table, for the use of invalids, and to assist digestion; machines for shelling green peas, broadbeans, &c.; cutting and mixing machine for hounds' food; pulper for fowls' food; bread cutter; machine for paring, coring, and slicing apples; egg whip, suet and parley chopping board, tobacco knife and board, coffee and spice mills, set of vegetable cutters, and machine for cutting French and scarlet beans.

MACNAUGHT AND SMITH, Worcester.—Tandem and Malvern dogcarts, shooting and Norway carts, Stanhope wagonette, miniature landau and brougham, and village basket cart.

M'NEILL AND CO., Bunhill row, London.—Asphalted roofing felt, inodorous bituminous felt, dry hair felt, and models in illustration.

MANCUR, E., Agent for Robert Hughes, Birmingham.—Double and single barrel sporting guns, breech loaders and muzzle loaders; rifles, carbines, muskets, pistols, and Colt's revolver.

MAPPLEBECK AND LOWE, Birmingham.—Chain harrows, cast steel draining tools, digging, border, and hay forks, spades and shovels, chaff cutters for hand and power, platform and other weighing machines, mangles, pumps for water and galvanized for manure, oilcake breakers, scarifier or tormentor, wood sack cart on iron wheels, grindstones, rack and manger, cast iron stable furniture, portable forge, brewers' hop press, strand wire fencing, tubular and angle-iron field gates, hurdles, hand road-scraping machine, single lever cheese press, iron corn bin, wood tub watering engine, three-row corn drill, galvanized water barrow, vermin traps, and models.

MARCH AND PATTISON, Leicester.—Cooking ranges and apparatus, eccentric cutting press, screw and rolling presses, pricking and skiving machines, hollow iron and block lasts, bundle of knives, swivel stand and socket, and sample board of malleable castings.

MARKALL, J. T., 7, Union-street, Whitechapel.—General joiner, for sawing, rabbeting, grooving, tenoning, boring, &c.; and self-acting cross-cut saw bench.

MARSDEN, H. R., Leeds.—Second-size patent stone breaker; stone, cement, coprolites, and ores crusher; four-horse power portable steam engine to drive the above.

MARSHALL, SONS, and Co., Gainsborough.—Nine-horse,

eight-horse, and five-horse power portable steam engines, three-horse power vertical, and two-horse steam pumping engine; combined thrashing and finishing corn dressers, straw elevators, and circular-saw benches.

MARTIN, W., 4, Shepperton-street, Islington, London.—Corroass nuts, or vegetable ivory, and miscellaneous lot of articles.

MATTHEWS, SON, AND CO., Driffield.—New corn-feeding cake as a substitute for linseed-cake.

MATTISON, WM., Bedale.—One right-hand delivery and one left-hand delivery reaping machine, each of one-horse power.

MAYNARD, R., Cambridge.—Portable sifting chaff engines, and spare knife wheels, powerful oilcake crusher, self-acting horse-rake, and six-horse portable steam-engine.

MELLARD, SOUTHWELL, AND CO., Rugeley.—Subsoil plough, lever cultivators, moulding or ridging ploughs, horse drag rakes, haymakers, pulpers, oilcake breakers, corn crushers, kibbling mills, chaff cutters, cheese presses, curd mills, malt mill, garden chairs, pig troughs, horse-power works, portable corn mill, six-horse vertical and horizontal engines, and wooden sheep rack.

MILFORD AND SON, Thorverton, Devon.—Salisbury, Leeds, and Plymouth first-prize two-horse waggon, and lifting-jack.

MITCHELL, W., Brandon.—Anti-diarrhetic compound feeding cake, and quantity of seeds.

MITCHELL AND BURGESS, Manchester.—Reaper-knife sharpeners, and portable stands for firmly holding the reaper-bar while being sharpened with emery or ordinary file.

MORRIS AND CO., Shadwell.—Collection of leather bands, fire-hose brass unions and hand branches, leather laces, fire-buckets, band screens, copper rivets and burrs, Green's patent fastener; collection of leather in hides and backs.

MORRIS, C., Leicester.—Five-motion pression and four and five-motion quadrant action beer engine, beer machines, shop rail opal and flint gas burners; two-light gas pendant in silver, opal, and ruby; ditto silver ball, opal arms, and cut drops; crystal star gas burner for ten lights, brilliantly cut with diamonds, and magnifying to 1,000 lights; also wrought-iron joiner's cramp.

MORTON AND CO., Liverpool.—An assortment of strained wire fence, straining pillars, tie and angle posts, wrought-iron gates, hurdles, galvanized roofing tiles, stiles, wicket-gate and sweep, with models of iron buildings.

MOULE'S PATENT EARTH-CLOSET CO., 29, Bedford-street, Strand, London.—Patent earth commodes and urinals, six sets of pull-up apparatus, portable iron drying stove, galvanized iron tank mounted on wheels, dustless earth and cinder sifter, sieve used for sifting the earth for the patent earth closets.

MULLINER, H., Leamington.—Wagonette, Whitechapel dog cart, basket pony phaeton, light hickory phaeton, sets of pony and other harness.

MUSGRAVE BROTHERS, Belfast.—Full-sized horse stalls with all the necessary stable furniture, cow-house fittings, iron piggy, dog kennel, encaustic and other stoves, &c.

MURTON AND TURNER, Thetford.—Corn-dressing machines, combined four-row mangold and turnip drill and lever horse hoe, small-occupation corn and seed drill, twelve-row swing steerage corn drill, twenty-row barley and seed drill, horse swathe rake, sample of steel forks, and sample of hand drills.

NICHOLSON, W. NEWZAM, Newark.—Cambridge clod crusher, land rollers, harrows, various hay makers, horse rakes, 1½ and 2½-horse stationary steam engines, portable steam engine and boilers, cake breakers, corn dressers, sack-lifters, patent clipper mower, croquet lawn mower, garden roller for pony, and double-cylinder rollers, wine racks, malt shovels, cooking and cottage bed-room gate.

NORTON, J. L., 38, Belle Sauvage Yard, Ludgate Hill, London.—Five-horse high-pressure vertical steam engine, nine-horse horizontal ditto, tube wells and pumps, apparatus for driving wells, Archimedian screw ventilators, chimney ventilators, silent fans, Root's American blower, oil tester, time and speed recorder for machinery or engines, and pressure recorder.

NYE AND CO., 79, Wardour-street, London.—Mincing, sawing, and masticating machines; also variety of mills, knife cleaners, butt taps with metal plugs, brushes, conservatory pump, &c.

OLDRAM AND BOOTH, Kingston-upon-Hull.—Six-horse

power bone mill with two pair of toothed rollers; also single-roller bone mill; two other bone mills, and six-horse power single-cylinder portable steam engine.

OWENS AND CO., Whitefriars, London.—Horizontal steam and centrifugal pumps, Cassiobury fire extinguisher, variety of other pumps and fire engines with requisite fittings, pulley and snatch blocks, water wheels, hydraulic rams, Townshend pail extinguisher, and portable engine tanks.

PAGE AND CO., Bedford.—Draining pipe, tile, and brick-making machines, leverage brick press, various ploughs, feed rollers, seed harrows, drag and diagonal iron harrows; turnip, bean, steerage, and combined expanding horse hoes; horse hay, corn, and stubble rakes; steam, horse, and hand-power chaff cutters; linseed-cake and bean mills, scuffers, corrugated iron sheep and pig troughs, and bench drilling machine.

PARKER, J., Kington, Leicestershire.—Thirty-eight kinds of English wool, twenty-six specimens of planked timber, twenty transverse sections cut from the root end of trees, nine patterns of veneer, five rolls of oak and other bark, and miscellaneous collection of wood specimens—all from the estate of the Duke of Rutland.

PARKES AND CO., Birmingham.—Sets and assortments of cast steel draining tools, digging and other forks, various tools for agricultural purposes, dung drags, potato shovels, centre strap, spades and shovels, axes, hooks, hoes, and hatchets.

PARE AND HAMSHAW, Leicester.—Cosy carts, Ariel wagonette, park phaeton, circular-fronted brougham, wagonette with moveable head, dogcarts, sociable landau, and ladies' car.

PEACOCK AND BUCHAN, Southampton.—Assortment of anti-corrosive metallic paints; also paint brushes, and patent can opener.

PEARSON BROTHERS, Gainsborough.—Few samples of pure linseed cake, ordinary cotton-seed cake, ditto of extra quality, samples of finest Petersburg linseed, and of Egyptian cotton seed.

PEIRCE, A. F., 109, Hatton Garden, London.—Tubular wheelbarrows; rotary general purpose liquid manure barrow pump, garden or fire engine; other pumps, self-coiling horse-reel, perpetual garden engines, corn bins, dust bins, portable furnace, step chair and expanding step ladders, straight ladder, tubular counterbalance, cash stand, expanding clothes horse; pig, sheep, and cattle troughs; taper-tail tripod manure pump, vase and pedestal, sack trucks, balcony chairs, piggeries or dog kennels, horse-rake; shovels, syringes and garden engines, aquapulta, flour bins, galvanized iron adjusted and stamped dry measures (from half-a-pint to a bushel), seamless milk cans, turnip skips, pails, buckets, economic potato washer, cinder sifter, knife cleaner, carpet sweeper, and box churn.

PENNY AND CO., Lincoln.—Radiating grain and seed separator, linseed dresser, adjustable rotary corn screens with blower and stone separators attached, also combined with winnowing and dressing apparatus; malt, gravel, lime, and coal screens; sack lifters with rack and chains, wire game netting, mea safes, woven wire, garden seats, arches, verandahs, and flower stands.

PICKERING, J., Stockton-on-Tees.—Patent pulley blocks and lifting chain, for raising and lowering weights from 5 cwt. to 2 tons.

PICKSLEY, SIMS, AND CO., Leigh.—"Excelsior" clod crusher, collection of chaff-cutters, oat and bean crushers and mills, corn crushers; turnip pulper, slicers, and strippers; Gardner's single and double-action turnip cutters, horse-rakes reaper, mower, and combined reaper and mower, American horse-rakes, grindstone and strong iron trough, wringing and mangling machines, pigtroughs, lawn mowers, garden seats, and rollers, sack trucks, and two-horse combined vertical steam engine and boiler.

PINFOLD, J. D., Rugby.—Two brick-and-tile-making machines, to make 15,000 and 20,000 solid or perforated bricks per day; also self-acting brick cutter, and a brick press.

POCHIN AND SON, Leicester.—Variety of sewing machines and writing desk, bronzed garden seats, arbour work-table, garden arches, engines, syringes, and seats; sets of croquet, meat safe with sliding shelf, birdcages, flower stands, corn bins, washhand stands, and patent cooking pot.

POCHIN, S. D., Leicester.—One hundred draining pipes, twenty roofing tiles, and six manger blocks.

PORTER AND CO., Lincoln.—Comstock's rotary spader for digging between hop-rows, and as a cultivator for light

soils; ditto for strong soils, and doing the breadth of four ploughs.

**POWIS, JAMES, AND CO.,** York Road, Lambeth.—Seven-horse power combined vertical engine and boiler; spoke-maker; four-cutter moulding and planing machine; steam-power tenon-cutter; endless-band sawing machine; circular and frame saw sharpener; noiseless disc fanblower; improved general joiner; self-acting circular-saw bench; hard or soft wood mortiser; mortiser, tenon-cutter, and borer; and mitre-cutter.

**POWIS AND CO.,** 51, Gracechurch-street, London, E.C.—Hand power mortising, tenoning, and boring machines; band-sawing machines; self-acting circular-saw bench, and improved joiner's saw bench; universal joiner, trying-up and planing machine, saw-sharpener, three-cutter moulding machine, and ten-horse power portable steam engine.

**PRIDMORE, GEO.,** Syston, Leicestershire.—Machine for winnowing all kinds of grain, and corn-dressing machine.

**PRIEST AND WOOLNOUGH,** Kingston-on-Thames.—Four lever corn-drills, grass-seed drill for horse power, manure distributor, drill for turnips and manure on the ridge; patent lever horse hoes, for light, mixed, and heavy lands; beam horsehoe for hoeing grain and root crops at any distance apart; three and five-tined horsehoes for wheat, turnips, mangold, &c.

**PROSKAUER, H.,** 69, Great Chart-street, Hoxton, London.—Transferable centres, corners, and borders, for ornamenting leather, papier-mâché, and japan goods; ditto landscapes and views, for flower-boxes and vases; bouquet [bouquets?] and flowers for transferring to glass windows; animals and their heads, for japan goods; ornamental plain and fancy covering, for carriage bodies; and miscellaneous sheets, for glass, &c.

**RANSOME AND CO.,** 10, Essex-street, Strand, London.—Weston's quick motion, triple-sheave, and other differential pulleys and chains; two and three-sheave "London pattern" rope pulley blocks; Haley's lifting jacks, hydraulic and agricultural ditto; Wilson's patent spanners, Schwartzkopf's self-acting spanners, automaton ditto, crank spanner, ratchet brace, freegrit grindstone, portable vice bench, roller punch, steam-pressure gauges, Schaffer's counting machine, Ransome's anti-friction metal, portable forge, wrought-iron parallel vice, sample of bolts and nuts, oxygen fire bar, needle lubricators, leather belting, driving band links, liquid manure pump, annular boiler, atmospheric churns, sack trucks, carriage setter, corn and flour bins, hothouse engine, garden engine, edge-cutting machine, garden seats, scales, traps, cooking apparatus, mincers, egg testers and beaters, knife cleaner, &c., and Long's Non-poisonous specific for sheep and wool.

**RANSOMES AND SIMS,** Ipswich.—Pony and one-horse ploughs, iron beam wheel and swing ploughs, digging and paring ploughs, double furrow ploughs, turnwrest and ridging or subsoil ploughs, potato raising, and other ploughs, iron plough sledge, new and improved plough wheels and irons, whippetrees and pomeltrees, harrows, horseshoes, haymakers, bean cutters, various mills, root-pulpers, turnip and chaff cutters, iron gear for two horses, rotary corn screens, lawn mowers, pig troughs, pans, single-slide expansion steam engines, double and single-blast steam thrashing machines, eight-horse power self-moving traction steam engine, improved straw elevator, patent caloric engine.

**RAVENSCHROFT, E.,** 150, Fleet-street, London.—"The Farmer" newspaper, "Journal of Agriculture," and "Country Gentleman's Magazine."

**READING IRON WORKS COMPANY.**—Read's subpulverizer plough, Spencer's roller and clodcrusher, six-horse high-pressure and condensing engine, seven-horse portable steam engine, 54-inch single-blast combined thrashing machine, horse-power thrashing machine and gear, American "clipper" mowing machine, saw bench with boring apparatus, double-action hay machine, lever horsehoe, thirteen-coulter chain corn drill, gorse-bruising machine, and oilcake mill.

**REVES, R. and J.,** Westbury.—Liquid manure, corn, and seed drills, broadcast manure distributor, water carts, harrow pump, and delivery pipe for water barrels.

**REID AND CO.,** Aberdeen.—General-purpose lever corn drill, and combined with horsehoe, horsehoe, barn weighing-machine, deer and cattle strained fence of galvanized strand wire and intermediate standards and straining pillars, with self-fixing wire straining post.

**RENDLE, W. E.,** 68, Welbeck-street, London.—Fruit-tree

and plant protectors, collection of agricultural and garden seats, and collection of agricultural and horticultural books.

**RICHES AND WATTS,** Norwich.—Two-horse-power portable steam engine, two-horse American heated-air engine, improved American grist mill on travelling carriage and another on low stand, also one to be driven by horse power; "Eureka" grist mills, "Domestic" and "Universal" grist mills and flour separator, aspirator for hand-power, one of greater capacity arranged with a riddle; "Excelsior" grain separator, American cradle washing and wringing machines, and carriage jack.

**RICHMOND AND CHANDLER,** Salford.—A variety of chaff cutters and corncrushers, horsegears, rootwashers, turnip-cutter, steaming apparatus, bread-kneading machines, four-horse steam engine, chaffcutters, and corncrusher.

**RIDE, JOSEPH,** Leicester.—Four-horse-power horizontal high-pressure steam engine, eight-horse Cornish boiler, portable corn mill on wooden frame, line of wrought-iron turned shafting, bearings, and pulleys; wrought-iron cylinder, stop valves, 18-inch pulley, man-hole lid for steam boiler, wrought-iron ring for joining boiler flues.

**ROBEY AND CO.,** Lincoln.—Eight-horse-power portable steam engine, thrashing and finishing machine, single-dresser thrashing machine, three-horse vertical engine with single cylinder, straw elevator, circular-saw bench, eight-horse traction engine, and fixed or portable corn mill.

**ROBINSON, ALFRED,** Leicester.—One-horse-power gas engine, requiring neither boiler, chimney, fuel, nor stoker; and steel-roller corncrusher or grinding mill.

**ROLLINS, J. G.,** Old Swan Wharf, London Bridge.—American pumps, suction, force, pitcher-spout, and yard; American aquarius, hydraulic rams, hay and manure forks, hayrakes, Nova Scotia grindstone, India pond extra scythe stones, horse rakes, thermometer churns, small American implements for farm and household use, weighing machines, &c.

**ROWELL AND CO.,** 9, Victoria Chambers, Westminster.—Improved fence, and also with gate combined, and an assortment of improved patent straining fence.

**RUSTON, PROCTOR, AND CO.,** Lincoln.—Portable steam engines, of six, eight, ten, and twelve-horse-power; double and single-blast thrashing and finishing dressing machines; improved straw elevator, and circular-saw benches.

**RYLAND, ALFRED,** Birmingham.—Assortment of Cambridge's patent firebrakes, steam pump, white metal for journals, malleable iron castings for agricultural implements, steel castings, and patent block composition for prevention and removal of incrustation in steam boilers.

**SALMON, TOMLIN, AND CO.,** Kettering.—Eccentric treadle and strong screw presses for cutting out boot and shoe soles, single and double; rollers for leather, and wrinking press; pricking machine for sprigging, split lift cutter, skivers for stiffeners, strip beader for uppers, six men's punches, iron lasts; assortment of thirty-six sickles; sheep shears; reaping, bagging, and bean hooks; hedging hooks, &c.

**SAMUELSON AND CO.,** Banbury.—Self-raking reapers, one and two-horse "Eclipse" reapers, grass mowers, combined reapers and mowers, turnip cutters, and lawn mowers.

**SAWNEY, WM.** (Trustees of) Beverley.—Winnowing, blowing, screening, and cliver machines, onehorse manual delivery reaper, sack elevators, hay collectors, sheep racks, garden seats, treadle grindstones, diamond swing for two children, and improved riddler.

**SHAND, MASON, AND CO.,** 75, Upper Ground-street, London.—Steam fire-engine as used by the metropolitan and other fire brigades, the British Admiralty, Russian, and other governments; also volunteer brigade fire-engine.

**SHARMAN, WARREN,** Melton Mowbray.—Several bundles of hay and corn rakes, drag rakes, twitch, couch, and stubble rakes, scythe sheaths, corn and flour bins, sack trucks, strained wire fence, meat safes, garden chairs, scuttle measures, &c.

**SHILLINGTON, T. F.,** Belfast.—Reaping and mowing machine with continuous cutting parts for saving nearly half the draughts and fitted with patent platform.

**SHUTTLEWORTH, J.,** Hathersage, Derby.—Pair of Peak millstones of the best description.

**SILVESTER AND CO.,** 16, St. James's Walk, Clerkenwell, London.—American knife sharpener and scale, patent bulling; stop valves, hammer, and steel measure or tape with side spring.

**SIMPSON AND HUTTON,** Northampton.—Seven horsepower portable steam engine.

SIMPSON, A., Westmoreland Walk, Chiswell-street, London.—Assortment of cattle spire, farinaceous food, case of silver cups and other prizes.

SKETCHLEY, W., Weymouth.—Six-horse portable steam engine, universal joiners, Betty saws, and mortising machine.

SMITH AND Co., Harbury, Warwickshire.—Combined mowing and reaping machine, horse rake and general drill, and general purpose horsehoes.

SMITH AND GRACE, Thrapston.—Grist mills for any kind of grain for hand or horse power, several chaff cutters, combined turnip cutter and root pulper, bean and cake mills, horse rake, turnip thinner and horsehoes combined.

SMITH, J. H., Conington.—Two-wheeled traps, termed "The Elect or Ladies' Dog-cart," and new windlarm for removing carriage head.

SMITH, WM., Foston, Yorkshires.—Self-feeding sheep racks, suited to all kinds of food, hayrack and shepherd's hut.

SMITH, Wm., Kettering.—Horse-hoes with steerage, and made with lever to lift at land's end, and to travel from field to field; winnower and blower, grindstone with a V edge, self-feeding reaper with Smith's patent scraper, sugar choppers, currant and raisin dressing machine.

SMITH, W., Royal Polytechnic, Regent-street, London.—Moveable letters, anti-corrosive silver-faced, for marking linen, and warranted not to oxidize.

SMITH AND SONS, Peasenhall.—Small-occupation corn-drill, nine to fifteen-row "Eclipse" corn-drills, a fifteen-row and fourteen-and-three-row corn drill, seven-feet manure distributor; turnip, mangold, and manure drill, and general-purpose drill.

SPENCER, J. AND T., Leicester.—New Guide to Leicester and map of the town; Guide to Charnwood Forest, Bradgate Park, &c., and stereoscopic slides.

SPONGE, J. O., 104, Fulham Road, London.—Revolving blow pipe; sausage and general mincing machine.

STAREY, T. R., Nottingham.—Light wagonette to form small omnibus for one or a pair of horses, phaeton in fine osier-work, framed cart, built of steel and hickory, and Queen's pattern basket-carriage to hold four persons.

STARTIN AND Co., Birmingham.—Village cart, park phaeton, mail wagonette, miniature broughams and barouche, and side-light landau.

STAYNES AND SONS, Leicester.—Leather and gutta percha endless driving bands, suction and delivery hose, waterproof covers, and indiarubber washers.

ST. PANCRAZ IRONWORK CO., Old St. Pancras Road, London.—Loose boxes and stalls with all necessary stable fittings and furniture, sheep and cattle hurdles, wicket and field gates, tree guards, garden seats, galvanized cast-iron sashes for cottages, pig troughs, feeding trucks, and turntables.

SUMMERSALES AND SON, Keighley.—Collection of washing, wringing, and mangling machines, on the dash-wheel principle.

SUTTON AND SONS, Reading.—Large collection of 100 specimens of dried grass plants, and samples of grass seeds; complete assortment of the principal kinds of agricultural, horticultural, and floricultural seeds; collection of the leading varieties of agricultural roots, and growing samples of various kinds of seeds in pots.

SWAIN, R., Braunston, Northamptonshire.—Four farm or poultry-yard gates.

TANGYE BROTHERS AND HOLMAN, 10, Lawrence Pountney Lane, London.—Special steam pumps with duplex boiler-feeder, four-horse portable steam-engine with cannon pump, differential pulley-blocks, hydraulic lifting and pulling jacks and punching bear, "Niagara" and other force pumps with hose, pails, hoisting crab, haley and screw jacks, rope blocks, and "Britannia" tank fire-engine.

TANNED LEATHER COMPANY, 81, Mark Lane, London.—Samples of driving straps and endless bands, with strap leaces.

TASKER AND SONS, Andover.—Twelve-horse power double-cylinder traction engine (Clayton's make); windlarm, with ropes, rope porters, and anchors complete for steam cultivation; Smith of Woolston's wrought-iron cultivator; apparatus for scarifying and drilling corn and other seeds, harrowing, and rolling in one operation, and to be worked by steam; harrow to be worked in conjunction with Smith's cultivator; set of three four-beamed trussed frame iron harrows, water cart, six-horse power portable steam engine, single-blast combined portable thrashing machine, improved portable straw elevator,

corn-dressers, two-horse portable thrashing machine, and screw jack.

TAYLOR AND Co., Adelaide Place, London Bridge.—Chaff-cutters, corn crushers, weighing machines, barrow Californian lift and force pumps, farmer's boiler, grindstones on iron and wooden frames, portable forge and bellows, bench and vice, corn bins, American churns, lawn mowers, garden seats, tables, arches, flower baskets, stands, chairs, and stools, also self-adjusting scythes.

TAYLOR, E., No. 1, Sussex-street, Manchester.—Eccentric churns, washing, wringing, and mangling machines.

THOMAS, C., Stratford-on-Avon.—Flexible side and other saddles, safety stirrup, Pelham curb and gag roller, variety of bridles and noseband.

THOMPSON, R. W., 3, Moray-place, Edinburgh.—Road steamer traction-engine on vulcanized indiarubber patent wheel tires, with vertical pot boiler.

THORN, CHARLES, Norwich.—Shooting carts, village phaeton, wagonette, Norwich car or ladies' carriage and suitable for children, silver and brass mounted single oob harness.

TINKLER, R., Penrith.—Churns of various sizes.

TIPPER, B. C., Birmingham.—"Medicated mystery;" and scab and tick ointment and powder.

TOMLINSON AND HAYWARD, Lincoln.—Butter powder for improving the quality and increasing the quantity of butter, making it sweet and firm in the hottest weather.

TOPHAM, C., Coleman-street, London.—Regulating machine for cutting food for poultry, suet cutter, sausage mincer, masticator, sausage filler, Canadian oilstone, screw wrenches, digging forks, self-expanding boiler-tube-cleaning brush and metal scraper, spiral wire and solid tube brushes.

TURNER, E., R., AND F., Ipswich.—Portable steam engines of four to ten-horse power, five-horse improved traction engine, and ten-horse fixed steam-engine; combined thrashing and dressing machines, straw elevator grinding and crushing mills, oilcake breakers, chaffcutters, malt mills, maize sheller, circular-saw bench, and gear work with intermediate motion.

TUXFORD AND SONS, Boston.—First-prize eight-horse-power portable steam engine, ten-horse improved horizontal-cylinder engines, sixteen-horse ditto with two cylinders, eight-horse steeple engine; one, two, three, four, six, and eight horse improved horizontal portable steam engines; prize ten-horse fixed steam engine; combined portable single-blast thrashing, shaking, and winnowing machines for four and six horse power engines, fitted with Coulson's spring hangers, Goucher's beaters, and improved riddles and shakers; combined thrashing, shaking, and perfecting machine; patent straw elevator to work at any angle, with self-feeding table and twenty-eight feet spout; double grinding mills, with one pair of French and one pair of Peak stones; portable single grinding mill in metal case and frame; Appold's centrifugal pump to throw 350 gallons per minute, and improved circular-saw table with parallel fence plate.

TYLER, WILLIAM, Melton Mowbray.—Wagonette, light dogcart painted blue, light varnished dogcart, and improved varnished Whitechapel.

UNDERHILL, W. S., Newport, Salop.—Five, seven, and nine-tine cultivators; six-horse power portable steam engine, traction engine, and thrashing, dressing, riddling, and finishing machines; blast elevators, Honnington scarifiers, twin-harrows, horse-rakes, two-furrow turnip drill, patching drill, ryegrass and cloverseed drill, hoes, grubbers, chain and Bedford harrows, cow crib, hand cart, sheep rack, cheese press, varnish-heating stove, and patent fences.

UNITE, J., 291, Edgware-road, London.—Model of thirty-load rick cloth, yellow and black and white cloths, waterproof and woollen trace and shill [thill ?] cloths, corn sacks, white anti-friction wheel grease, nosebags, sack tyes, horsecloths, tarred and white collar reins, web head halters, head stalls, hay rope, kersey horsecloths, hemp sheep netting, Archangel mats for fruit trees, and netting for same.

UPTON, JOHN, Atherstone.—Spring wagon for agricultural and miller's purposes, and  $\frac{1}{4}$  inch cart for general purposes, with harvest gear.

VARTY, NATHAN, Royston.—Six patent self-cleaning horse hoes, fitted with lifting apparatus for light and uneven land, and also for heavy land; two self-cleaning root-hoes.

VICKERS, SNOWDEN, AND MORRIS, Doncaster.—Wheel and swing ploughs, two-row combined mangold and turnip

drill, turnip cutters and slicers, and self-expanding horsehoes for light and heavy land.

WADDE, WM., Leeds.—Several revolving barrel churns, making from 2 to 80lbs. of butter, with electroplated air-discharge valves; also two tub churns.

WALKER, W., Titchley, Notts.—Fourteen-row corn, man-gold wurzel, and turnip seed drill, with steerage; 24-row cloverseed and ryegrass drill, with steerage, and easily worked turnip cutter.

WALLIS, HASLAM, AND STEEVENS, Basingstoke.—Eight-horse-power portable steam engine, and 54-inch double-blast thrashing and finishing machine.

WARNER AND SONS, 8, Crescent, Cripplegate, London.—Annular sail wind engine; a variety of lift and force pumps, fire engines, garden engines, swing water barrows, syringes, aquajets, fountains, firebells, steam fittings, sluice valves, "Noria" water lift, and chaff cutter for wind engine.

WEBB AND CO., Worcester.—Bags of dissolved bones; bean, pea, and vetch manure; wheat and potato manures, bone superphosphate of lime, nitrophosphate, turnip and mangold manure, hop manure, concentrated bone manure, ground bone ash, shoddy manure, Angamos and Peruvian guano, and palm-nut meal.

WEBB, L., Stowmarket.—Leather machine bands in great variety, fire buckets, delivery and suction hose, leather laces for lashing bands, cut soles from English butts, tan sheep leather, wool lamb skins, strap butts, and tanned calf-skins.

WEIR, E., 142, High Holborn.—Washing, wringing, and mangling machines; indiarubber wringers and starchers, mangles, gofferers, clotheshoes, chair and steps, lawn garden seat, portable wardrobe, ladies' foot holders, sabots, Norwegian self-acting cooking apparatus, "lightning" apple-parer, fruit-press, mincers and sausage makers; mills for grinding coffee, pepper, spice, rice, &c.; egg and butter [batter?] whisks, zinc syringes, burglar alarm, portable folding ladder, &c.

WHEELER, BENJ., Nottingham.—Simple, plain, well made, and portable conservatory, and two garden chairs.

WHEELER AND SON, Gloucester.—Collection of farm seeds.

WHITE, JOSEPH, 15, Trinity-street, Southwark.—Specimens of oil-feeders and needle lubricators, artificial dams, save-all pyramidal oilcans, barn lanterns, leather bands and straps, lashing laces and thongs.

WHITEHEAD, J., Preston.—Handpower drain pipe, tile, and brickmaking machines; double-box steam-power ditto; improved hand-power brick pressing machine, solid brick maker, and six-horse-power portable steam engine.

WHITMEY AND CO., 103, St. John-street, Clerkenwell, London.—Several corncrushers, three steel flour mills, also mills with Derbyshire Peak and French burr stones for power, domestic flour mills for handpower, linseed and malt mills, flour-dressing machine, and sausage makers.

WILKINS, T., Ipswich.—Two, four, and five-horse portable steam engines; mills for grinding corn and pulse of every description, charcoal, spices, drugs, &c.

WILKINSON AND SON, Ely.—Lever self-adjusting horse hoe adapted to all the prevailing methods of drill culture.

WILLIAMSON BROTHERS, Kendal.—Six-horse power portable steam engine, vortex turbine wheel, whirlpool centrifugal pumps and blowing fan.

WILSON AND CO., 210, Regent-street, London.—Hand and treadle sewing machines of various descriptions, plain and handsomely finished.

WILSON AND CO., 5, Lime-street, London.—Twelve-horse double-cylinder portable steam engine; one-horse portable pumping and driving steam engine; donkey steam pump for feeding boilers; universal steam engine of one-man's power, and specimen of impregnable iron fencing.

WILSON, J., Penrith, Cumberland.—Bottles of "The Preservative" and "Perfect Cure" sheep bathing, "Improved sheep-dipping powder" and "Dipping Composition."

WINDOVER, C. S., Huntingdon.—Huntingdon wagonette made of hickory and steel, Hilton dog-cart, park phaeton, Dagmar pony cars, Stanhope phaetons, miniature circular-fronted broughams, boat-shaped barouche; other dog-carts, phaetons, and sociables, American buggy, and Southern Brett.

WOOD, WALTER A., 77, Upper Thames-street, London.—Grass-mowers, and one and two-horse reapers; also a Nova

Scotia grindstone for sharpening the knives of mowing machines.

WOODS, COCKEDGE, AND WARNER, Stowmarket.—One, two, and four-horse vertical steam engines; 42-inch and 36-inch portable French burr corn-grinding mill; 30-inch Peak stone portable corn-mill; two-horse power portable corn-mill, "universal" mill, crushing roller mills, pulpers, turnip cutters, oilcake breakers, horse-works, two-horse thrashing machines, saw tables, poppy and weed extirpator, zigzag roll, improved one-horse carts, perfect pig-troughs, asphaltum apparatus, root pulper, double barley rolls, Cambridge's press wheel roller, three-cylinder field and pasture roll, ditto with four cylinders, eight-horse double-cylinder vertical engine, large chaff cutter; line of shafting, with pulleys, blocks, standards, &c.; two-horse mower and reaper; model drying apparatus for agricultural produce.

WOOLLEY, JOSEPH, Allestree, Derby.—Derbyshire waggon, strong one-horse cart, light ditto, market cart, and tandem Scotch cart.

WRIGHT AND SON, Great Bently, Essex.—Grass seeds and specimens, and agricultural seeds and roots.

WRIGHT, H., Boston.—Straw elevators and stacking machines, also portable horse works.

### THE RECEIPTS AT LEICESTER.

Brick and Tile Yard (one day, 408 persons, £102.)  
Sale of Catalogues about £800.

First day (5a.)	3,052 persons	£763 18 0
Second day (2a. 6d.)	10,290 "	1,291 5 3
Third day (2a. 6d.)	5,987 "	813 2 8
Fourth day (1a.)	52,462 "	2,629 3 10
Fifth day (1a.)	24,538 "	1,226 18 0

96,329

The following Comparative Returns were issued on Monday night:—

### BURY ST. EDMUNDS, 1867.

First day (5a.)	910 persons	£237 15 0
Second day (2a. 6d.)	4,465 "	557 11 0
Third day (2a. 6d.)	7,880 "	985 8 6
Fourth day (1a.)	33,126 "	1,657 15 0

46,387

### PLYMOUTH, 1865.

First day (5a.)	1,063 persons	£265 16 0
Second day (2a. 6d.)	4,767 "	595 11 10
Third day (2a. 6d.)	17,269 "	2,150 0 0
Fourth day (1a.)	24,943 "	2,147 14 10

60,042

It will be seen that the one bad day at Leicester was on the Saturday, attributable to the end of the week and the inconvenient arrangement of cutting the Show time in two.

### SHORTHORNS AT THE COUNTY OF CORK SHOW.

—The annual show of the County of Cork Agricultural Society was held on Thursday, July 24, in the City of Cork Corn-Exchange. The exhibition of Shorthorns was a good one, as may be inferred when we find Mr. Smith, of Islandmore, in the field with his prize-taking bull Liector, from the Mullins-bro' herd, and also "Chief of Lothian," from the Ardret pastures, which stood first and second respectively, against five others which formed the section of aged bulls. In the yearling bulls, Photograph, bred by Mr. Welsted, took the Meade and Garde £50 cup as the best yearling bull in the yard, Mr. Henry Barry, Ballyadam, coming in second with Ali Murad, a Soubadar bull out of a cow, Sally, also from Mr. Welsted's herd. Mr. G. Colthurst got highly commended for Knight of Lothian. Of fourteen bull calves Mr. Smith, of Islandmore, with The Governor, bred by him, by Liector, took also the Welsted Challenge Cup, as the best bull calf in the yard. Mr. Welsted had won this cup twice in succession; Mr. H. Massey's unnamed calf was the second; J. Downing's Pasha and Mr. Welsted's Royal Knight were highly commended. In the

cow section Mr. Welsted's Rosette led the way, Mr. Barry's Sally, a Welsted cow, taking second; Mr. Meade's, of Ballymartle, and Mr. H. Massey's commended. In two-year-old heifers Mr. Welsted's Princess Primrose was first, as also the winner of the prize for the best two-year-old heifer bred in the county, Mr. George Ronaldson coming in second. In the

yearling heifers, Colonel Fisher took the first prize, and the Meade and Garde Challenge Cup, Mr. Welsted's Rosanna second, and also the prize for the best yearling heifer bred in the county. Mr. H. Massey's Wood Rose highly commended. Mr. J. Downing, Ashfield, Fermoy, took the prize for the best Shorthorned heifer calf.

## ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MONTHLY COUNCIL, Wednesday, August 4, 1868.—Present: His Royal Highness the Prince of Wales, K.G., president, in the chair; Viscount Bridport, Lord Chesham, Sir A. K. Macdonald, Bart., Mr. Bramston, Mr. Cantrell, Colonel Challoner, Mr. Clayden, Mr. Druce, Mr. Edmonds, Mr. Brandreth Gibbs, Mr. Hassall, Colonel Kingscote, M.P., Mr. Ransome, Mr. Shuttleworth, Mr. Torr, Mr. Wells, Professor Simonds, and Dr. Voelcker.

The following members were elected:

Addison, J., Brookfield, Gretton, Uppingham  
 Best, James, jun., Hill Top, Tenbury  
 Booth, John, Shenstone Hall, Lichfield  
 Bowen, James Bevan, M.P., Llwyngwair, Haverfordwest  
 Bramley-Moore, J., Gerrard's Cross, Bucks  
 Burnham, Robert, Leicester  
 Butler, Richard, Radcliffe-on-Trent  
 Carding, Frank, Combs Farm, Farnsfield, Southwell  
 Costaworth, John, West Wickham, Bromley, Kent  
 Cresswell, Mrs. Gerard, Appleton Hall, King's Lynn  
 Culley, George, Fowberry Tower, Belford, Northumberland  
 Dowdeswell, Arthur C., Pall Court, Tewkesbury  
 Gray, Edward, Moscow Works, Sheffield  
 Hamel, Alfred John, Lancaster Place, Leicester  
 Harris, Charles T., Knighton House, Leicester  
 Harris, John Dove, Ratcliffe, Leicester  
 Harrison, Colonel B., Kynastone, Ross  
 Harrold, G. A., Leicester  
 Idlip, Francis W., Collegiate House, Leicester  
 Jarrold, Joseph, Leicester  
 Johnson, T. F., Stonegate, Leicester  
 Jones, John, Mars-y-pandy, Tan-y-llyn, Merionethshire  
 Judkins, Mrs., 4, Ludgate Hill, London, E.C.  
 Lamin, William, Bestwood Park, Nottingham  
 Lewis, Samuel, Audley, Newcastle-under-Lyne  
 Mannington, Wm., Laughton Place, Hurst Green  
 Meakin, Henry James, Shobnall Grange, Burton-on-Trent  
 Moore, George, Whitehall, Wigton  
 Oakley, Christopher, 10, Waterloo Place, London, S.W.  
 Ord, George, Brixton Hill, Surrey  
 Petre, Edward, Whitley Abbey, Coventry  
 Richardson, Francis E., Brumshall, Uttoxeter.  
 Roeling, Edward, Droxford, Southampton.  
 Roselyn, The Earl of, Easton Lodge, Dunmow, Essex.  
 Slee, Henry H., Leicester.  
 Stamper, Thomas, Highfield House, Oswaldkirk, York.  
 Stone, Samuel Francis, Eldon House, Leicester.  
 Summerfield, Joseph, Green Barn, Lichfield.  
 Taylor, Thomas Swift, The Frith, Leicester.  
 Thompson, James, Leicester.  
 Thorold, Sir J. A., Bart., M.P., Syston Park, Grantham.  
 Tinkler, Henry, Holmfirth, York.  
 Townsend, George, Oulton Cottage, Lowestoft.  
 Walker, Frederick T., 39, Harley Street, London, W.  
 Warner, Thomas, The Abbey, Leicester.  
 Webster, Charles, Waltham Abbey, Essex.

FINANCE.—Major-General Viscount Bridport, Chairman of the Committee, presented the Report, from which it appeared that the Secretary's receipts during the past month had been examined by the Committee, and by Messrs. Quilter, Ball, and Co., the Society's accountants,

and were found correct. The balance in the hands of the bankers on July 31 was £7,288 10s. 9d., the sum of £2,000 remaining on deposit. Cheques to the amount of £6,596 4s. 1d. were ordered to be drawn. This report was adopted. The half-yearly audit of the Society's accounts to the 30th June, 1868, took place on the 4th instant.

COMMITTEE OF SELECTION.—The name of the Earl of Lichfield, who resides in the same district as the late Earl of Shrewsbury, was recommended to fill the vacancy in the Council, and having been proposed by Colonel Challoner, and seconded by Viscount Bridport, his lordship was unanimously elected a member of Council.

Mr. Brandreth Gibbs having moved that a committee consisting of the stewards and honorary director be appointed to consider and report on the means to be adopted in future to ensure the awards being issued in due time, the motion was agreed to. Mr. Torr gave notice that he would bring on in November his motion that the Society have a special reporter at the Council and other meetings. Viscount Bridport moved that a committee consisting of His Grace the Duke of Richmond, K.G., Earl Cathcart, Viscount Bridport, Lord Chesham, Sir A. Macdonald, Bart., Mr. Bramston, Mr. Dent, M.P., Mr. Edmonds, Mr. Brandreth Gibbs, Mr. Wren Hoskyns, Mr. Randall, Mr. Thompson, and Mr. Wells be appointed to consider the testimonials of candidates for the office of Secretary and Editor, and to report the result of their investigations to the Council in November.

MANCHESTER MEETING. — The following noblemen and gentlemen were appointed a Committee for the Society's Country Meeting in 1869:—Duke of Richmond, K.G., Chairman; Duke of Rutland, K.G.; Earl of Powis, Viscount Bridport, Lord Chesham, Lord Kesteven, Lord Portman, Lord Tredegar, Lord Vernon, Lord Walsingham, Hon. H. G. Liddell, M.P.; Sir E. C. Kerrison, Bart.; Sir Henry R. Vane, Bart.; Sir Watkin W. Wynn, Bart.; Mr. C. E. Amos, Mr. Charles Barnett, Mr. Edward Bowly, Mr. Charles S. Cantrell, Colonel Challoner, Mr. John Clayden, Mr. D. R. Davies, Mr. J. D. Dent, M.P.; Mr. B. T. Brandreth Gibbs, Mr. E. Holland, M.P.; Mr. Richard Hornsby, Mr. C. Wren Hoskyns, the Mayor of Manchester, Mr. Richard Milward, Mr. Thomas Pain, Mr. Charles Randall, Mr. R. C. Ransome, Mr. C. S. Read, M.P.; Mr. William Sanday, Mr. Joseph Shuttleworth, Mr. N. C. Stone, Mr. William Torr, Mr. James Webb, Mr. William Wells, Major Wilson, Mr. Jacob Wilson, the Stewards.

The Agreement with the Mayor and Town Clerk of Manchester having been read and considered, the common seal of the Society was affixed by the secretary.

## THE YORKSHIRE AGRICULTURAL SOCIETY.

## MEETING AT WETHERBY.

Notwithstanding that the material of the Yorkshire Show is mainly supplied from the county itself, the meeting at Wetherby came very much in echo or rather in commentary on the doings at Leicester. Almost all the great winners in all the great classes, such as the Shorthorns, the riding horses, the long-wools, and the pigs, were here again ready to try further conclusions; and as any man who had acted as a judge at the one meeting was declared to be ineligible for the other, a certain additional interest was thereby attached to the proceedings. And, certainly, these second "sets" appeared by no means inclined to be influenced by any ruling of any other learned brethren; an independence of action more particularly observable in placing the cattle, or in other words the Shorthorns, for no other kind of beast is exhibited in Yorkshire. With, in all its chief features, precisely the same competition, seconds were put first, firsts were put third, while some were put out and others left in, on the inexorable axiom that every man may have an opinion of his own. There was not so much to do at Wetherby as there had been at Leicester, neither was this altogether so well done, and at the very outset the award over the old bulls created something like a sensation. Amongst those that met here again were Mr. Booth's Commander-in-Chief, Mr. Peel's Knight of Knowlmere, Mr. Lynn's Prizeman, and Mr. Fawkes' Friar Bacon, some of which in the interim have been on their travels, the Commander and Prizeman winning at Grantham, and the Knight of Knowlmere at Heslington. Still, even the very hot weather had not told much on any of them, and the four may be taken as entering the ring in much the same form in which they did at Leicester. However, after a long consultation, during which Mr. Stephenson seemed to be holding out, the Royal award was reversed, and the white put first and Mr. Booth second. Commander-in-Chief, as we have already written of him, may not be at all points a perfect animal, but he is surely superior to Knight of Knowlmere; and should the two come together again before a fresh lot of judges, we doubt if the Wetherby decision can ever be confirmed. The white is in reality not much of a show bull; for he is ungainly in his action, drooping in his carriage, and his chief recommendation a certain masculine character, associated with a deal of coarseness and plainness. The Commander-in-Chief, on the contrary, is a very handsome, stylish, "taking" bull, with, as we have said, his weak place or two; but the decree, grounded more on a butcher's than a breeder's estimate of value, was pretty generally disputed by the connoisseurs outside. Prizeman and Friar Bacon were highly commended as at Leicester, and a very good-looking lengthy bull of Major Stapylton's put in for third prize, as, indeed, had he been more made up, he might or should have beaten the other white, whose good luck has more than once brought him a little too forward. In a really bad lot of two-year-old bulls, Charles le Beau, the only one in from Leicester, had a long lead, neither the second nor third being really prize animals, and the judges discreetly withholding any further compliment. On the other hand, the yearling bull was comparatively a strong class, and a still stronger illustration of the difference of opinion which exists amongst Shorthorn judges. Lady Pigot's Rosolio third here, was second at the Royal Leicester and first at Grantham; while Mr. Foljambe's

Knight of the Thistle first at Wetherby, was second to Rosolio at Grantham; and Mr. Fawkes' Lord Belmore merely commended at Leicester, second at Wetherby. Then Mr. Lynn's Grand Sultan, the best of his class at Louth against some of his "betters" here, got now no higher than a commendation; and Captain Oliver's smart Cherry Butterfly, the best yearling at Oundle and the third at Louth, was now never noticed at all. By this, we should lay down the lines for judging a Shorthorn, or according to such a system, or rather the want of a system, it would seem to go very much on the toss-up of a halfpenny. However, the winner here is a light, lengthy, well-shaped animal, with more quality than substance; while the capital coat of Lord Belmore must have had a deal to do with getting him so forward, as it served to cover more than one weak place. Rosolio is now as well known as his trusty squire John Ward himself; but a very good class was made out by some fresh entries nearer home, including a couple of terribly high-bred ones from Scaleby Castle.

It will be remembered that a deal of discussion took place at Leicester as to which was really the better of Mr. Foljambe's two bull calves, then placed first and second; and it would have been interesting enough to have seen them out together once more. But in the exercise of some very neat diplomacy the Royal first will not be brought out again this season; and so the second best was left to do battle at Wetherby. Such as upheld his merits at Leicester would now seem to have no cause to qualify their admiration, for Knight of the Crescent not only took the first prize of his class, but the cup as the best of all the bulls, as his half-brother Robin did at the same age at Doncaster. We are inclined to doubt the policy of thus distinguishing very young animals, but this is certainly a capital calf, long, deep, and square, of a good whole colour, with a handsome roundish head, and very nice and kindly in his quality; so that it was thought he would have even beaten Commander-in-Chief "on their merits." Mr. Foljambe was also third with another son of the Knight of the Garter, on a heavy but plain scale, and with bad drooping quarters. The couple were separated by a particularly nice young bull of Mr. Cattley's, that was immediately put in price, and Mr. Smith, of Wetherby, commended for a white, with only half a pedigree, by second Duke of Wharfedale, out of nobody knows what.

Of that "sweetest, straightest, and altogether most charming cow" Lady Fragrant, how shall we say more than we have said? save that she was, of course, the best of her class, and the winner of the cup as the best of all the cows and heifers. It was stated that a hundred to one was actually laid on Mr. Booth's bull, but still greater odds might have been given over his cow. Her second at Leicester, Jolly Queen, was not at Wetherby, but Queen of Rosales, the third at Leicester, and that might have been second, was now passed by, in favour of the "gandy-vulgar" Miss Farewell. We can but repeat our own words, as we register perhaps the most faulty decision of the day. Putting Lady Fragrant out of any question, the judging of this class was saved by the placing of the second cow, a white, from Osberton, merely commended at Leicester, but worthy of more notice. Cherry Blossom begins with a nice cow's head and a fine forehead, has well sprung ribs, a capital back, and great breadth over

her loins; but she is growing a little gaudy about her tail, and is rather hard in her touch—a point which must go greatly against her, with those who judge with their eyes shut. A good deal was thought of Sir Walter Trevelyan's Princess of Yetholm, the best cow at the recent Northumberland meeting, but she did not fulfil her promise, and was neither fancied inside nor outside the ring; while Mr. Dugdale's entry had more merit, and would be selected amongst the three or four really good cows in an otherwise moderate class. There were only four two-year-old heifers, over which the three premiums were reluctantly awarded, as Mr. Dugdale's Cherry was the only one with any pretensions to a place on a prize-list; but the yearling heifers, like the yearling bulls, were numerous enough and good enough to furnish some further example of "the eccentric movement" by which Short-horn judging seems to be regulated. At Leicester Mr. Howe's Lady Anne was first, Mr. Booth's Patricia second, something else third, and Mr. Booth's Lady Gaiety highly commended. At Wetherby, where the three named also met, Lady Gaiety was first, Patricia second, and Lady Anne third! It is only fair to say that this is the third time in succession since the Royal Show that Lady Gaiety has been preferred by other judges to Patricia; and Lady Gaiety, be it remembered, is own-sister to Lady Fragrant; but it is hard to understand how, with her great growth and fine deep frame, Lady Anne could have been put aside. It is true, as we have previously pointed out, that she shows to some advantage on the score of age; but as long as she was in the class she was at the head of it. We believe that she has never before been beaten; and full of promise as are Mr. Booth's pair, with Lady Gaiety for choice, the allowance for age—always a difficult matter to adjust—was surely made too much of at Wetherby, and such leading points as size and symmetry hardly put at what they are worth. Sir George Wombwell's high commendation was very fairly earned with a pretty red roan, purchased at the late Lord Feversham's sale; and the entry, with Mr. Tennant, Mr. Dugdale, and Lord Londesborough in it, was pretty generally good. In a small class of heifer calves Mr. Foljambe was first again, with a capital straight, stylish roan, with well laid shoulders, and a line of beauty running along her, in very striking contrast to the light mean second, bad before and behind, and with nothing but her hair to recommend her, although Mr. Douglas was supposed to have gone for this one, with much vehemence! There were four dairy cows entered for two prizes, which having been duly awarded, the owner of the commended cow, as also of the second prize, felt it to be his duty to enter the ring and inform the judges that the commended one had beaten the other two whenever they had previously met. And this brought the business to a climax, the Wetherby trio having upset everything they well could, even to the placing of two or three Milk-maids and Dairy-maids.

The Show, be it said, was held in Mr. Gunter's grounds; but this gentleman is very much above exhibiting his Duchesses, although rumour ran riot as to a yearling heifer still to be seen all alive, and just sold for 1,000 gs., to go to America, on the express understanding that she is never to come back again. This rather reminds one of the story of the master's instructions to his man, touching the sale of a favourite horse: "You take him to the fair to-morrow, Will, and mind you don't bring him back again!"

Amongst the horses that entered the ring at Wetherby there was a capital muster of the right sort in many of the classes, even for Yorkshire; and, with dealers from all parts in search of something with form and fashion equal to the bulky dimensions of Daniel Lambert, down to that diminutive bit of humanity, General Tom Thumb,

prices were high, but not so exorbitant as to stop business. The two sets of judges commenced their duties about half-past nine in adjoining rings; but they were not well handicapped, as the cart and coaching bench were very quick in coming to their decisions, while the thorough-bred and hunter trio were the reverse, and the former might have been entrusted with the roadster classes without even then a chance of making a race of it. Among the thoroughbred stallions, nine in number, there were the first and third at Thirsk last year, Angelus and Volturmo; the latter a fashionable-looking horse, with his toes out as if he had been dropped at Almack's, and hocks none of the cleanest, was nowhere here; while the neat, good-topped, short-jointed, hunting-like horse of the class, Grand Master, though nowhere at Thirsk, was placed third here; the long-necked, hollow-backed, dishing King Brian taking the second rosette. Then, the lengthy, good-limbed Windham, with hocks not quite in a line, and the useful Scaramouch, by Touchstone, with the brilliant-coated, over-topped, short, light-armed Laughing Stock, a taker of the Royal Hundred at Newcastle, and who still bent his knee, were no where. The other two were Schloff and Cathedral, the one spoilt by straggling, and weak hind-leg action, and Cathedral with quite enough of him, and quality for anybody, if in better form. Young Ebor, in the coaching stallions, a six-year-old, and never shown before but as a yearling, was a fine lengthy horse, with good ends and short legs; and General Johnson not deficient in appearance or limbs. The roadster stallions were very well represented by a class of eighteen, many of them being well-known, in the ring, and, as is customary with this class of horses, some wearing necklaces, and one a breeching of local prizes printed on brass plates. Fireaway, the first horse, is of good form and great character, and he was picked out for honours at York three years ago, but disqualified by the veterinarian for lameness. The second, Edwin Landseer, a son of Fireaway is a stylish-looking trotter, and a black, like his sire, but not so compactly made, nor with the old one's character. The third, or commended, for his number was posted as a winner, was All-Fours, renowned as a prize-taker and for his neat form and merry-going, white-stockinged legs; indeed, he would have been asked to take a higher place if it had not been for his poor feet, which have been brought into their present form by some British remedy. Among the others was Young Pretender, with a good top and well-set limbs, as well as being a grand mover, who took second honours at Thirsk last year, and who, many thought, ought to have been presented with the first. St. Ives, the second at Driffield to All-Fours, that we noticed last week, was also here, and Captain Barlow's handsome cob Lucifer, together with Bucks, Princes, Liberators, Performers, and Pretenders, as well as other well-known high-stepping names. The hunting brood mares with foal at foot, or, as "the model Secretary" loves to put it, "with foals sucking" but they are not always imbibing like ourselves, were very well represented, the grand topped Lincolnshire lass and prize lady of Leicester, Maid of the Heath, having to make way for three others; one of these being Goahead, that was placed third to her at Leicester, and, which though of smaller dimensions, is more symmetrical. Then Slippers, who, after considerable deliberation and sundry drenchings in the heavy storms that occurred at Thirsk during the holding of the prize-court, was placed first, and Goahead nowhere; but here the tables were reversed, with Goahead second and Slippers nowhere. But of all the old dames there are none like the varmint, rare-made, short-limbed, one-eyed Sally, a prize-taker when the Royal was held at canny Newcastle. There were several other nice ones; but we find, if we enumerate all with good-looks, we should be as long in summing up as the judges were

in getting at their decisions. British Queen, picked out as the queen of beauty from the Leicester roadster brood mares, was here fain to accept of second honours to The Maid of all Work, a mare in her twenty-second year, and whose beauty, if she ever had any, must have left her in the years of hard toil, or become soured by the too common badgering accompanying the not over-paid services of the ill-fated sisterhood. Polly, a deformity, came in for the third rosette, with a model of whose heavy forehead and faulty forelegs the judges ought to be presented by the Society as a memento of their services, and if the designer could add her hammering action, so much the better. Brunswick, a short-quartered leggy chesnut by Angelus, was first in anything but a grand class of two-year-olds, the second being a good-limbed, fine-framed bay by King Caradoc; while the third, Jordan, was of a good form, but of no quality. Then a fair-made filly, with four white legs, and the usual accompanying blaze of white in the face, by Angelus, was first, and Britannia, a Laughing Stock, rather high on the leg, second, a position she also filled at Birmingham; while Mr. Burton's The Star by Cain, from Thirak, was a fine-looking mare. In a well represented class of three-year-old hunting geldings, Don Juan by Angelus, a great quartered chesnut, that drew his hind legs after him as if he were ashamed of them, was placed before The Sultan, a gelding of some form, but light of bone and back at the knee, and who had a knack of bringing his flat feet in rather too close proximity with his shins; and the third, Bullfinch, we considered the best, a deep, compact, short-joint brown, with his hocks well under him. Mr. Stapylton's Solferino was very handsome, though there was not much of him; while Mr. Botterill's General Napier had a good forehead but short quarters, and Mr. Beilby's brown by King Brian had something more pleasing about him than his sire.

The roadster three-year-olds were fairly represented, though not strong in numbers, Dudee being a nice one, but rather long from the knee to the ground; while Rifleman looked like making either a clever hack or light hunter, a rare but excellent combination; and Mr. Gunter's Pioneer and Mr. Davis' roan gelding were the next that attracted our attention. Although only four in number, the three-year-old hunting fillies were anything but a poor lot, the first, Eleanor, being a fine-shaped mare, with good limbs, by Volturmo, and the second, Nelly, by Pioneer; the others, a grey, Sadowa, by Pontifex, of Major Stapylton's, and a chesnut, by Anderby, of Mr. Clarke's, of Thirak. The four years old, seventeen strong, out of an entry of twenty-six, made up a very good class, the chief honours going to Brigadier, who now leaves the nursing and good things of Killerby Hall for active service with the Holderness. But putting him alongside old Wrangler or The Doctor will not improve his looks, as he has somewhat of a coarseness about him, more especially in his hind-quarters, besides a flourish with his off fore-leg, that denotes anything but pace. Then he has feet the size of a fly flapper, which, certainly, may be of use to him in crossing a slushy country, or in case of a swim, should he happen to drop his satchel rump into a bumper in the shape of a dyke. The second horse, Harry by Bondholder, dam by St. Bennett, was far more taking, and we thought more the cut of the Holderness stud, with length, middle, capital ends, and first-rate limbs, as well as being full of quality, and throughout trussed with muscle, but free from lumber, so that we shall look out this nag again, as there is something genuine in him, or we are much mistaken. The third, a bay by Fugleman, could step, but was light about the knee. Mr. Brady Nicholson's The Baron, with length, was of fair form, and Mr. Robson's The General by King Caradoc of good shape;

but Julius by Orpheus, a prize-taker at Bridlington, is an overgrown one that looks higher than he is, a fault that speaks for itself. Amongst the four-year-old hunting fillies there was nothing to brag about, and from the glimpse we had of them Bird of Eve is rather narrow, but Mr. Barton's Gem had some shape; Carnation was wiry, and wearing-looking, and Mr. Darrell's Princess neat and light. Of five-year-old hunters by a thorough-bred horse, up to 14 stone, there were five—Lady Derwent, Emperor, Borderer, Mr. Brady Nicholson's Beeswing, and Mr. Cattle's Royal Oak. The tug of war was with the three former, the first prize going to Lady Derwent, who as some think is scarcely up to the weight. She cantered prettily, but is anything but a strong goer; while the second was the sour-eyed Emperor, second to her in the all-aged cup at Driffield, and though compact and truly built, he does not bring his hind legs well under him in his gallop. The third was the grand hunting-like weight-carrier Borderer, who would have stood more chance in sticky ground than on that nearly equal to the turnpike-road. In the twelve-stone class, also by a thorough-bred horse, there were twelve competitors. Highborn, a nice-looking horse, but light below knee and a trifle leggy, goes rather high and round for a hunter, as well as carrying his neck very stiff and ewed when set going. The second, Errand Boy by Fugleman, dam by Muley Moloch, is a very handsome blood-like horse, of beautiful symmetry and capital stylish action, bringing his hind legs under him in his canter in elegant style, that would make him, with his looks, more valuable as a park hack than a light hunter. The Princess is a nicely-formed mare, barring a slight thickness in the shoulder, but with manners for which Humberton is noted. Peach, a handsome chesnut mare of Mr. Wright's, of Nottingham, would neither walk nor trot, or do anything but bound about like a grasshopper, making it anything but pleasant diversion for the gentleman up, if we are at all acquainted with physiognomy. Tallyho, a chesnut of Mr. C. Harrison's, has something grand in his looks; but, as he cannot move, he did no more than he did at Driffield—come in at one end and go out at the other. Mr. Brady Nicholson has a horse in Bacchus, that when on he never need fear soiling his boots or charging anything short of a windmill, as he is a capital fencer; and Mr. Fawcus, of Darlington, had a very hunting-like horse in the Baron, by Orphod, dam by Fitzambo. In the six-year-old hunters, Sprig of Nobility put in an appearance; but Master of Arts, who stood next on the list, shirked it, as his coat begins to shine, after the pains we have taken with him, and the dressings we have given him to get him into tip-top show condition; and a judge who once gave him honours, not only abhors the very name, but won't stop in a yard with the chesnut. Mountain Dew was here too, and, after a heavy thunder-storm, which made horses, judges, and lookers-on skeddadle for shelter, and the turf much better going, the black galloped in his old form, that gained him the first rosette at Manchester. He steps very high in his trot, and a little so in his gallop; but he has a sweeping stride, and goes and feels like a hunter under you, bringing his hind legs well under him. This has always been our opinion of him, which was confirmed by Mr. Brady Nicholson, a good horseman, who rode him at Manchester, as well as judged him; then Captain Skipworth, who rode and judged him there also and again at Wetherby, is no novice in crossing a country, and still sticks to him in preference to the wooden ones that used to sweep the decks. Tyreconnel, the second Islingtonian to Mountain Dew, came to try his luck again before his shoulders bring him to grief; and Mr. Jacob Smith rode in on a good-looking chesnut, who could go, and who was one of the half-dozen picked ones; but

while we were having a glance at something else, Tranby had vanished. Cavendish, a horse by Oxford, that struck us at a first glimpse as more like harness, has a thick neck and a coarseness throughout, as well as being light of bone, but a good mover. Among the others were several good-shaped ones; and Iris, who beat Lady Derwent at Peterborough, as *he* ought to have done, or *she*; for, if our eyes did not deceive us, *he* was a horse, and if the name do not, *she* must be a mare; but he, she, or it, Iris is a clipper of surprising beauty. He is a model of a hunter, for symmetry and power, with quality throughout; besides this, he is a strong goer, bringing his hind legs under with such powerful but even strokes, as he goes sailing away, with his head pointed, as true as the needle to the north. We have seldom seen a horse as a hunter that we have been more pleased with, and we took him for sixteen hands only, so beautifully is he made; but Pye, the Captain's stud groom, who has hands, and showed his horse well and quietly, assured us that Iris is within an ace of sixteen-two, and one of the best, which is saying a good deal, that Mr. Anstruther Thomson ever crossed. He is a bay with a wall eye, which had a most comical appearance, when with quite an old lady's night cap in the shape of rosettes pinned to that side of the head he paraded the ring full of honours, for he beat them all, and carried off the president's silver cup, for the best hunter exhibited in any of the classes, which included Lady Derwent, who in action for a hunter or power was but a neat hack by the side of him, Brigadier, Highthorn, Eleanor, Don Juan and other winners. In the hackneys up to fourteen stone there were several very nice nags, old Crafty playing second fiddle to the Malton bay, while Thorngumbald's Pride, the Birmingham lass, was nowhere. Garibaldi, who was first last year at Thirsk, where we sang his praises, was again at the head of the poll in hacks up to twelve stone; but The Duchess of Athol we did not see out, nor any of this class. Captain Barlow's clever little hack Piccadilly, with plenty of bone, who it will be remembered was second to Mr. Millward's The Steward, at Thirsk last year, in the ponies above twelve hands and under fourteen hands, has greatly improved, and now heads the list.

In the agricultural stallions, Lincolnshire is a grand and well-made horse, of size, but with not the best of heads, which, with a small eye and only one ear, is not improved, the other ear being injured by a twitch, and withered; but in other respects, there is not much to find fault in him. The second, Young Sampson, is a useful, active, good-limbed horse, who took the third ribands at Leicester. Mr. Bell's Emperor was a good-looking sample of the Clydesdale breed, but rather light in the middle; and Mr. T. Child's Royal, somewhat of a heavy roadster of the Norfolk type. The well-known Jet, first at Leicester, carried all before her here, Bonny the second being a deep, cobby, active, short-legged mare, of good stamp; and Mr. Aitkin's Rose, a good-framed one on short legs, but with a big head. In the two-year-old geldings and fillies there was no entry, and in the three-year-olds but three came into the ring; the first, Topper, being an active, light, calf-kneed stepper, and the second thick and useful. In the pairs of four-year-olds and upwards, Dick and Charley, a handsome light pair of greys, from Myton Hall, beat a heavier, good-looking couple, with more power in Punch and Toby, or as the paper lads at Doncaster station love to pronounce that great individual's name, Poonch and his rival Phoon.

With the exception of the Leicesters the show of sheep was not very imposing, and the three Down or Short-wool men had not much to say over what they saw. There were no Southdowns proper, and amongst the Shropshires there was not a sheep nor even an owner who had taken a prize at Leicester. Lord Wenlock and

Mr. Horton were the chief winners, and the Esrick ewes were a fair useful pen, Mr. Horton's second being, as we believe, the lot disqualified at Leicester. Mr. Peel had as usual all the honours to himself with his Lonks in the mountain or black-faced class; and there was in reality no competition amongst the Cotswolds. Mr. Lynn made a few entries under the condition of "other long-wools," but Mr. King Tombs took all the prizes with his famous 200 gs. sheep and others in, or put out at Leicester. Although the Lincolns have here the honour of a recognized rank, the entry beyond the prize sheep was not equal to the front offered at the Royal in a more general class. The shearing rams were altogether the best lot, with Mr. Wright first with the sheep, also first at Leicester; Mr. Marshall being now second with the third at Leicester, and Mr. C. Williams' second prize Royal sheep now not noticed. Amongst the old rams Mr. Marshall stood precisely as at the Royal meeting, with the same sheep first and second, the judges only adding one commendation in a class of some numerical strength. Mr. Cartwright's first-prize pen of gimmers at Leicester took nothing at Wetherby, Mr. Wright's third prize at the Royal being now put over them as first, while Mr. Lister's second-best here were not at Leicester. We can only repeat that the Lincolns are very deservedly making way on the show-ground for a combination of good wool and good mutton; but the proof at Wetherby, so far as the prize-list be concerned, is little better than negative, and, as with the Shorthorns, a man must study the two returns very carefully if he should not feel strong enough to judge for himself.

The Leicesters were, as we then said, very good at Leicester; and they were very good at Wetherby, although with Colonel Inge, Mr. Sanday, and Mr. Turner well out of the way, Mr. Borton had, beyond his own county, only Mr. Cresswell and Mr. Marris to beat; and, with one exception, he took all the prizes. His first-prize Shearling was third at Leicester, the second was not at Leicester, and the third sheep was highly commended at Leicester; so that the one award goes to confirm the other. Amongst the old sheep, however, the decision was reversed; the "reserve" of the Royal being now first, and the second Royal again second. The judges of Leicesters, though they spoke well of the general show of the breed, were somewhat chary of their commendations, despite such exhibitors as Mr. Cresswell, Mr. Riley, Mr. Marris, and Mr. Brown bringing their sheep on, many of which had been previously and deservedly noticed.

The competition in the pig classes was pretty generally limited, although the quality of even the big Yorkshire pig is evidently being amended. Amongst the large white boars there were only four entries for three prizes, Messrs. Duckering's best Leicester pig getting no nearer than third, and then only under protest, as he was very lame. The best large white sow—a wonderfully good one—was also first at the Royal meeting; but Mr. Dyson here again interfered with the previous decisions, and the Northorpe sow was consequently only third, instead of second. In the boars of a small breed, Mr. Mangles' white, never noticed at Leicester, took first, and Mr. Eden's Suffolk, then first, was now put second; and so on. The mixed breeds were very bad, as going for neither one thing nor the other, and the three store pigs, even with Mr. Mangles' first and third, not much better; but in the pigs under twelve months Mr. Eden had a capital boar of the large white breed; and the small boars of the same age made up a very good class. There have been larger shows of pigs in Yorkshire, but never better; and for very visible advancement in the breeding of this kind of stock, Wetherby will offer some very satisfactory proof.

Mainly, as it would seem, for the amusement of two gentlemen appointed to act as judges, a variety of fantastic premiums were offered for implements in the yard, all of which were duly awarded, and all of which will be found duly chronicled in our prize-list. It would be impossible to offer any further commentary on so harmless an occupation.

The Hound Show, as we have long insisted it should be, was this year made a show of itself; but in consequence of the tedious plan of extending the horse-judging into the second day, very few people had time to visit the hounds, and as a speculation the affair could not have paid. Neither were the hounds so good as we have seen them; while the success of the thing was seriously damaged by a bit of official absurdity which went to prevent the judges announcing their awards as they made them. Only imagine the public watching half-a-dozen horse-classes out and in again, without any information as to what was going on! Mr. Parrington, however, if we remember aright, did once attempt something of the same sort with a horse show, under the notion that people would attend at some dinner to hear the awards announced and the speeches made. Let there still be dinners and speeches by all manner of means, and view-halloos and hurrahs and so forth, for those who like this kind of business; but let the world run and read, and then eat its dinner in quiet, assuming that it should so desire to do.

## PRIZE LIST.

### CATTLE.

JUDGES.—J. Douglas, Athelstaneford, Drem.  
C. Howard, Biddenham, Bedford.  
M. Stephenson, Fournstones, Hexham.

### SHORT-HORNS.

Bulls of any age above three years old.—First prize, £20, J. Peel, Clitheroe (Knight of Knowlmore); second of £10, T. C. Booth, Northallerton (Commander-in-Chief); third of £5, H. M. Stapleton, Myton Hall, Yorkshire (Lord Wetherby). Highly commended: J. Lynn, Grantham (Prizeman); F. H. Fawkes, Otley (Friar Bacon).

Bulls above two and not exceeding three years old.—First prize, £20, Lady Pigot, Newmarket (Charles le Beau); second of £10, J. W. Botcherby, Darlington; third of £5, T. D. Jefferson, York (Lord Waterloo).

Bulls above one and not exceeding two years old.—First prize, £20, G. S. Foljambe, Worksop (Knight of the Thistle); second of £10, F. H. Fawkes, Otley (Lord Belmore); third of £5, Lady Pigot, Newmarket (Rosoleo). Highly commended: J. Lynn (Grand Sultan).

Bull calves above five and not exceeding twelve months old.—First prize, £10, and cup value £20 as best of all the bulls, G. S. Foljambe, Worksop (Knight of the Crescent); second of £5, J. Cattley, York (Prince Leopold); third of £2, G. S. Foljambe, Worksop (Knight of the Thistle). Highly commended: A. Dugdale, Burnley (Duke of Brunswick). Commended: J. Smith, Wetherby (Yorkshire Hero).

Cows of any age above three years old, in calf or milk.—First prize, £20, and cup value £20 as best of all the cows and heifers, T. C. Booth, Northallerton (Lady Fragrant); second of £10, G. S. Foljambe, Worksop (Cherry Blossom); third of £5, R. Tennant, Leeds (Miss Farewell). Highly commended: Lady Pigot, Newmarket (Queen of Rosalea); A. Dugdale, Burnley (Lady Fortunate).

Heifers not exceeding three years old, in calf or milk.—First prize, £15, A. Dugdale, Burnley (Kent Cherry 2nd); second of £7, J. Smith, Tadcaster (Silverspring 3rd); third of £3, R. Houfe, Wetherby.

Heifers not exceeding two years old.—First prize, £15, T. C. Booth, Northallerton (Lady Gaiety); second of £5, T. C. Booth (Patricia); third of £3, J. How, Huntington (Lady Anne). Highly commended: Sir G. O. Wombwell, Bart., Easingwold (Georgina); R. Tennant, Leeds (Rose of York).

Heifers calves above five and not exceeding twelve months old.—First prize, £10, G. S. Foljambe, Worksop (Flora); second

of £5, R. J. Hudson, Barley-in-Wharfedale (Achievement); third of £2, A. Dugdale, Burnley (Kirkleavington Rose).

Cattle of any breed.—Cows for dairy purposes.—First prize, £10, R. Brogden, York (Milkmaid); second of £5, J. T. Robinson, Thirsk (Milkmaid). Commended: J. T. Robinson, Thirsk (Dairy-Maid).

### EXTRA STOCK.

First prize, first-class silver medal, C. Wright, Tadcaster (Shorthorn ox); second, second-class medal, Lieut-Colonel Markham, Aberford (Bramin).

### SHEEP.

#### JUDGES.—Longwools—

W. Bartholomew, Waddington Heath, Lincoln.  
G. Garne, Churchill Heath, Chipping Norton.  
R. Woods, Osberton, Worksop.

#### JUDGES.—Shortwools—

H. Fookes, Whitechurch, Blandford.  
E. W. Moore, Coleshill, Highworth.  
C. Randall, Chadbury, Evesham.

### LEICESTERS.

Shearling rams.—First prize, £15, J. Borton, Malton; second of £7, J. Borton; third of £3, J. Borton. Highly commended: J. Borton.

Aged rams.—First prize, £10, J. Borton; second of £5, J. Borton. Highly commended: J. Simpson, Wetherby.

Shearling gimmers.—First prize, £10, J. Borton; second, T. Maris, Ulceby. Highly commended: S. Wiley, York. Commended: E. Riley, Beverley.

### LINCOLNS.

Shearling Lambs.—First prize, £15, R. Wright, Nocton; second of £7, W. F. Marshall, Branston; third of £3, J. W. Richardson, Kirtou Lindsey. Highly commended: R. Wright.

Aged rams.—First prize, £10, W. F. Marshall; second of £5, W. F. Marshall. Highly commended: J. W. Richardson.

Shearling gimmers.—First prize, £10, R. Wright; second of £5, C. Lister, Colely Lodge, Lincoln. Highly commended: T. Cartwright, Danstan Pillar, Lincoln.

### COTSWOLDS OR OTHER LONGWOOLS.

Shearling rams.—First prize, £15, J. K. Tombs, Langford, Lechlade; second of £7, J. K. Tombs; third of £3, J. K. Tombs.

Aged rams.—First prize, £10, J. K. Tombs; second of £5, J. K. Tombs.

Shearling gimmers.—First prize, £10, J. K. Tombs; second of £5, J. K. Tombs.

### SHROPSHIRE DOWNS.

Shearling Rams.—First prize, £15, Lord Wenlock, Bourton, Much Wenlock, Salop; second of £7, T. Horton, Harnage Grange, Shrewsbury; third of £3, T. Horton. Commended: Lord Wenlock, Esrick Park, York.

Aged rams.—First prize, £10, T. Maris, The Chase, Ulceby; second of £5, Lord Wenlock, Bourton. Commended: D. R. Davies, Mere Old Hall, Knutsford.

Gimmers.—First prize, £10, Lord Wenlock, Esrick Park, York; second of £5, T. Horton. Commended: T. Horton.

### MOUNTAIN OR BLACKFACED SHEEP.

Shearling rams.—Prize, £10, J. Peel, Clitheroe.

Aged rams.—Prize, £5, J. Peel.

Ewes.—Prize, £5, J. Peel.

### EXTRA STOCK SHEEP.

First silver medal, J. and E. Tindall, York (Leicester ewes); second silver medal, G. Wright, Malton (Leicester ewes). Highly commended: J. W. Sharp, Bridlington (Leicester ewes), and W. Brown, Holme-on-Spalding Moor (Leicester ewes).

### P I G S .

#### JUDGES.—Large breed—

W. Bartholomew  
G. Garne  
R. Woods.

#### JUDGES.—Small breed—

H. Fookes  
E. W. Moore  
C. Randall.

Boars, large breed.—First prize, £5, J. Dyson, Leeds; se-

cond of £2, G. Chapman, Scarborough; third of £1, R. E. Duckering and Son.

Sows, large breed, in pig or milk.—First prize, £5, P. Eden, Salford; second of £2, J. Dyson, Leeds; third of £1, R. E. Duckering & Son, Kirtton Lindsey.

Boars, small breed.—First prize, £5, G. Mangles, Ripon; second of £2, P. Eden, Salford; third of £1, W. Sagar, Bradford. Commended: R. E. Duckering & Son.

Sows, small breed, in pig or milk.—First prize, £5, P. Eden, Salford; second of £2, C. H. Dawson, Otley; third of £1, R. E. Duckering & Son. Highly commended: J. Dyson, Leeds; W. Sagar, Bradford. Commended: G. Mangles.

Boars, of any breed, not qualified to compete in large or small classes.—First prize, R. E. Duckering & Son; second of £2, W. Sagar; third of £1, P. Eden.

Sows of middle breed, in pig or milk.—First prize, £5, R. E. Duckering & Son; second of £2, E. Harrison, Leeds; third of £1, P. Eden. Commended: R. E. Duckering & Son.

Three store Pigs, of any breed, and of the same litter, from four to nine months old.—First prize, £5, G. Mangles; second of £2, H. Routledge, York; third of £1, G. Mangles.

Boars of large breed, not exceeding 12 months old.—First prize, £3, P. Eden; second of £1, J. Dyson.

Sows of large breed, not exceeding 12 months old.—First prize, £3, R. E. Duckering & Son; second of £1, G. Chapman, Scarborough.

Boars of small breed, not exceeding 12 months old.—First prize, £3, W. Sagar; second of £1, S. Blakey, Otley. Commended: J. Dyson.

Sows of small breed, not exceeding 12 months old.—First prize, £3, W. Sagar; second of £1, J. Dyson. Highly Commended: R. E. Duckering & Son; commended, T. Nicholson, York.

#### EXTRA STOCK.

First-class silver medal, J. Dyson (boar).

#### HORSES.

##### JUDGES.—Riding Horses—

E. M. Burbidge, Thorpe Arnold, Melton Mowbray.  
C. Garfit, Whitegate, Northwich.  
J. Skipworth, Howsham, Brigg.

##### JUDGES.—Coaching and Cart Horses—

J. Outhwaite, Bainesse, Catterick.  
A. Turnbull, Cresswell, Morpeth.  
W. Young, Norwood House, Beverley.

Stallions, thorough-bred, for getting weight-carrying hunters.—First prize, £30, Sir George Cholmley, Bart., Howsham, York (Angela); second of £10, Earl of Harewood, Harewood House, Leeds (King Brian); third of £5, J. R. Dennison, Minsthorpe, Pontefract (Grand Master).

Stallions for getting coach horses.—First prize, £20, T. and J. Reynolds, Carlton, Selby (Young Ebor); second of £5, I. Hairsine, Broomfleet, Brough (General Johnson).

Stallions for getting roadsters.—First prize, £20, P. Triffitt, Home-on-Spalding-Moor, York (Young Fireaway); second of £5, P. Triffitt (Sir Edwin Landseer). Commended: H. R. W. Hart, Dunnington Lodge, York (All Fours).

Stallions for getting agricultural horses.—First prize, £20, M. Strickland, Headley Hall, Tadcaster (Lincolnshire); second of £5, J. Edmondson, Entwistle, Burnley (Young Sampson). Commended: T. Child, Seacroft, Leeds (Royal Oak).

Brood mares for breeding hunters, with foals at foot.—First prize, £15, J. Brown, Wiggonby, Wighton, Cumberland (Sally); second of £5, J. T. Robinson, Leckby Palace, Thirsk (Go-ahead). Commended: G. and C. Lancaster, Morton Grange, Northallerton (Chesnut).

Brood mares, for breeding coach-horses, with foals at foot.—First prize, £10, W. and F. Coulson, Gaterley Farm, Castle Howard, York (Venus).

Brood mares for breeding roadsters, with foals at foot.—First prize, £10, H. R. W. Hart, Dunnington Lodge, York (Maid of All Work); second of £5, F. Cook, Thixendale, York (British Queen). Commended: W. Major, Sledmere (Polly).

Brood mares for breeding agricultural horses, with foals at foot.—First prize, £10, W. Tennant, White House, Barlow, Selby (Jet); second of £5, R. W. Eddison, Headingly Hill, Leeds (Bunny).

Two years old hunting geldings.—First prize, £10, Sir G. Cholmley, Bart., Howsham, York (Brunswick); second of £5, W. and B. Muzeen, South Holme, Slingsby (bay). Commended: T. S. Cundy, Hall Orchards, Wetherby (Jordan).

Two years old hunting fillies.—First prize, £7, Sir George Cholmley, Bart., Howsham, York (Britannia); second of £3, J. W. Gardom, Butterton Park, Newcastle, Staffordshire (Flirt).

Two years old coaching geldings.—First prize, £10, L. Mansfield, Thirkley Barff, Thirsk (bay); second of £5, T. Robinson, Wingate Hill, Tadcaster (brown).

Two years old coaching fillies.—First prize, £7, L. Mansfield, Thirkley Barff, Thirsk (bay); second of £3, J. Donaldson, Great Ayton, Northallerton (Topsy).

Three years old hunting geldings.—First prize, £15, Sir G. Cholmley, Bart., Howsham, York (Don Juan); second of £10, S. A. Hall, Kiveton Park, Sheffield (Sultan); third of £5, Viscountess Downe, Baldersby Park, Thirsk. Commended: R. Botterill, Garton, Driffield (Bullfinch).

Three years old hunting fillies.—First prize, £10, R. Wise, Field House, Sewerby, Bridlington (Eleanor); second of £3, J. Moor, Scalp Park, Selby (Nelly).

Three years old coaching geldings.—First prize, £15, J. Casson, Burgh-by-Sands, Carlisle (Comedian); second of £10, G. W. Appleyard, Angram Hall, Easingwold (brown); third of £5, Haigh and Sons, Bramham College, Tadcaster (Kurnool).

Three years old coaching fillies.—First prize, £10, W. S. Robinson, Thormauby, Easingwold (bay).

Three years old roadster, geldings or fillies.—First prize, £10, R. Nelson, Barton Hill House, York (black brown); second of £3, R. Emmerson, Over Dinsdale, Darlington (Rifleman).

Three years old agricultural geldings or fillies.—First prize, £7, W. Tennant, White House, Barlow, Selby (Topper); second of £3, T. H. Preston, Moreby Hall, York (black).

Pairs of four years old and upwards agricultural geldings or mares, regularly worked up to the time of the show.—First prize, £7, H. M. Stapylton, Myton Hall, Boroughbridge (Dick and Charley); second of £3, Crawshaw and Blakeley, Dewsbury (Punch and Toby).

Four years old hunting geldings.—First prize, £25, J. B. Booth, Killerby, Catterick; and also highly commended for the President's Cup (Brigadier); second of £10, T. Clayhills, Darlington (Harry); third of £5, Wm. Kendall, East Ness, Oswaldkirk (bay).

Four years old hunting fillies.—First prize, £15, J. B. Booth, Killerby, Catterick (Bird of Eve); second of £5, J. W. Clarke, Guisborough (Carnation).

Five years old hunters, geldings or mares, by a thorough-bred horse, up to 13 stones and upwards.—First prize, £25, E. Hornby, Flotmanby, Ganton, and also highly commended for the President's Cup (Lady Derwent); second of £10, W. Stephenson, Bush Hill, Brough (Emperor); third of £5, J. A. Thomson, Brixworth, Northampton (Borderer).

Five years old hunters, geldings or mares, by a thorough-bred horse, and up to 12 stones and upwards.—First prize, £20, L. Hodgson, Highthorn, Easingwold (Highthorn); second of £7, H. Jewison, Raisthorpe (Errand Boy); third of £3, J. Smith, Humburton, Boroughbridge (Princess).

Hunters, six years old and upwards, geldings or mares.—First prize, £25, and the President's Silver Cup, value £25, as the best hunter, gelding, or mare exhibited in any of the classes, J. A. Thompson, Northampton (Iris); second of £10, E. N. Heygate, Buckland, Leominster (Mountain Dew); third of £5, George Steel, Workington (Cavendish).

Gentlemen's hackneys, of any age or sex, up to 14 stones and upwards.—First prize, £10, F. P. Newton, Norton, Malton (bay); second of £5, H. J. Percy, Howsenrigg, Aspatia (Crafty).

Gentlemen's hackneys, of any age or sex, up to 13 stone and upwards.—First prize, £15, H. Milner, Harrogate (Garibaldi); second of £5, H. Roundell, Queen's Head, Otley (Duchess).

Ladies' hackneys, of any age or sex.—First prize, £10, Sir G. Cholmley, Bart., Howsham, York (Belinda); second of £5, G. Whitehead, Riccal Hall, York (Nizza).

Ponies, above 12 and not exceeding 14 hands high.—First prize, £10, F. Barlow, Castle Donington, Derby (Piccadilly); second of £5, J. Backhouse, Weston, Selby (Jessy).

Ponies, not exceeding 12 hands high.—First prize, £10, W. F. Fox, Dewsbury (Pretty Jane); second of £5, Marchioness of Hastings, Castle Donnington, Derby (Bobby).

#### EXTRA STOCK—HORSES.

First-class silver medal, R. W. Eddison, Headingley Hill, Leeds (Brown); second-class silver medal, S. Wimbush, Finchley, London (Young Ellington).

#### CHEESE.

JUDGES (and for butter).—A. Robinson, Upperhead Row, Leeds.

W. Wilson, Coney Street, York.

Cheese, not less than 1 cwt., made since Oct. 1, 1887, the produce of one dairy.—First prize, £5, G. Gibbons, Tunley Farm, near Bath; second of £2, G. Gibbons.

#### BUTTER.

Fresh butter, 8lbs. in single pounds.—First prize, £3, Mrs. Taylor, Harewood, Leeds; second of £2, J. Hatfield, Oswaldkirk, York; third of £1, J. Abbey, Crimble, Knaresborough.

#### WOOL.

JUDGE.—J. Clayton, Ripley.

Five hogg fleeces, long-wool.—First prize, £3, M. Tomlinson, Cowthorpe, Wetherby; second of £2, C. Barroby, Baldersby, Thirsk. Highly commended: C. Wright, Tadcaster.

Five hogg fleeces, short-wool.—First prize, £3, T. Horton, Shrewsbury; second of £2, T. Marris, Ulceby.

#### IMPLEMENTS.

JUDGES.—T. P. Dods, Anick Grange, Hexham.

T. C. Johnson, Chevet, Wakefield.

#### First-class silver medals to:

For waggon for farmers' use, the Beverley Iron and Waggon Company.

Cart, the Beverley Company.

Market cart, Firmin and Co., Retford.

Chaff cutter, for power, Pickaley, Sims, and Co., Leigh, Manchester.

Oat crusher, for power, Ransomes and Sims, Ipswich.

Portable saw bench, Marshall, Sons, and Co., Gainsborough.

Stand of saddlery, M. Cooper, York.

Collection of weighing machines, Mrs. Mason, Alford, Lincolnshire.

Collection of churns, W. Warde, Leeds.

Collection of washing machines, T. Bradford, Manchester and London.

Collection of land tools, H. Hall, Wetherby.

Stand of waterproof covers for stacks, waggons, carts, &c., G. Mudford, Retford.

Stand of iron hurdles, T. Hyde, Sheffield.

Stand of wire work, T. Hyde.

Collection of pulleys and hoists, J. Pickering, Stockton-on-Tees.

Stand of varied descriptions of food for cattle, Matthews and Co., Driffield.

Stand of artificial manures, H. Richardson, York.

#### Also recommended for first-class silver medals:

J. Fowler and Co., Leeds, for steel traction engine.

Beverley Iron Company, for improvements in clod crushers.

H. R. Maraden, Leeds, for stone breaker.

Driffield Cake Company, for samples of cake.

#### Second-class silver medals to:

Fer turnip cutter for cattle, Ransomes and Sims.

For sheep, E. H. Bentall, Maldon.

Oilcake breaker for cattle and sheep, W. N. Nicholson, Newark-on-Trent.

Oat crusher for hand power, Pickaley, Sims, and Co.

Bean splitter, Ransomes and Sims.

Sheep rack for hay and cake, Wm. Smith, Foston, Driffield.

Field gate, T. Hyde.

#### Also recommended for second-class silver medals:

H. Wilks, Bramham, for improvements in pumps for deep wells.

Ashby and Jeffery, Stamford, for improvements in haymaker. Vickers, Snowden, and Morris, Doncaster, for self-expanding horsehoe.

#### HOUNDS.

JUDGES.—Viscount Galway.

Lord Herries.

Mr. J. Parrington (Cleveland).

Mr. D. R. Scrutton (Essex).

Two couples of entered Hounds, dogs, no hound being older than a seven-season hunter.—First prize, £20, Lord Kesteven, Stamford; huntsman, J. West, £5. Second prize, £10, Earl of Yarborough, Ulceby; huntsman, N. Long, £3.

Two couples of entered Hounds, bitches, no hound being older than a seven-season hunter.—First prize, £20, Lord Kesteven; huntsman, J. West, £5. Second prize, £10, Earl of Yarborough; huntsman, N. Long, £3.

Un-entered Hound, dog, pupped since the 1st December, 1866.—First prize, £10, Sir C. Slingsby, Bart., Knaresborough; kennel huntsman, W. Orvis, £5. Second prize, £5, Lord Hawke, Pontefract; huntsman, E. Owen, £2.

Un-entered Hound, bitch, pupped since the 1st December, 1866.—First prize, £10, Sir C. Slingsby; huntsman, W. Orvis, £5. Second prize, £5, Sir C. Slingsby; huntsman, W. Orvis, £2.

Stallion Hound, not less than a three-season hunter, and certified to be the sire of living puppies.—Prize, £10, Earl of Yarborough; huntsman, N. Long, £3.

Brood Bitch, having reared a litter since the 1st December, 1866.—Prize, £10, Earl of Yarborough; huntsman, N. Long, £3.

At the Council Meeting on Thursday it was resolved to hold the Show in 1889 at Beverley.

## AGRICULTURAL MANUAL LABOUR.

Mr. H. FRAMPTON, of Watership, read a paper before the Newbury Farmers' Club. The following are extracts:—"The subject of 'Agricultural Manual Labour' is one of importance, and in the absence of any other paper, I have consented to introduce it; but having had only a short time to prepare it, I must beg you to excuse a hurried and imperfect paper, still I trust by bringing forward some of the principal points, a really good and animated discussion will ensue, so that in the end some lasting good may result. It will be my object to treat this subject as fairly and openly as possible, remembering the golden rule, 'To do unto others as I would they should do unto me,' feeling assured that it is a question of such momentous importance as to require the most careful and candid consideration of all those concerned. Before entering into the general subject of this question, I would pause to say a few words in reply to those would-be philanthropists who appear to delight in making us (the employers of agricultural labour, in short the farmers of England) the 'butt' at which to cast

their darts. We hard-hearted mortals are made to appear, to those who are not acquainted with the real facts, as tyrants; but I say it behoves all who make a charge against others to search and see if they are founding those charges upon a right foundation—upon the truth—and, if not, to pause ere they speak words which cannot be recalled. Mr. Frampton then referred to an account of a testimonial recently presented to Canon Girdlestone, from a number of labouring men, 'in grateful remembrance of his successful efforts to raise their wages.' The assertions made by Canon Girdlestone, that the agricultural labourers were unjustly treated by the farmers, he contended, were without foundation, and that most of those gentlemen who found fault with the employers of agricultural labour were utterly unacquainted with the real condition of the British farmers as to the question of whether they were able to raise the price of wages. He continued:—'I distinctly say that under present circumstances we cannot raise the wages of our labourers to the extent required by these gentle

men; we cannot afford it. Farming is not sufficiently profitable, and if we are made to do so the loss must fall upon the landlords ultimately; it is useless to pay more than we shall ever see again, and the plain unvarnished fact is that the profits derived will not admit of our paying higher wages. I am quite sure and convinced farmers are not adverse to paying higher wages, provided they can make those wages remunerative. I think there is not a right-minded employer of labour but would quite as soon pay his men 20s. per week as 10s., provided they can make themselves worth it; it would be better, as the master would not require so many labourers, consequently have fewer to look after and to find work in wet and bad weather, when you can make scarcely any return for their labour. I am not writing with the idea of keeping down wages; that I do not desire; but under the circumstances I ask, can farmers afford to pay higher wages? I distinctly say they cannot, and ultimately this must become a landlord's question. But we find these sentiments of Canon Girdlestone's shared by others much nearer home. Mr. Frampton then referred to some correspondence that took place early last year in the Reading papers on the "price of bread," in which "Miller" states that farmers "had better try, if possible, to mend the condition of the poor farm labourer, whose wages are regulated most unjustly;" until they do this they will continue to be "the butt" of the benevolent portion of the community. Mr. Frampton then continued:—I emphatically assert it is not and cannot be our wish to keep down the price of labour; we are willing to pay all we can afford if men will make themselves worth it, but I cannot and will not assent to this false assertion of "Miller's" that agricultural labourers' wages have not advanced. I distinctly say they have, and of course they must while others advance in trades, and there has been a gradual and considerable rise for many years. Neither will I believe, till it is more convincingly proved to my satisfaction, that our men are paid so much worse than townsmen; and when we take into consideration their houses, gardens, and perquisites in the shape of firing, beer, and many other things, in short, I know we pay all they are at present worth; and if these interfering gentlemen will not believe it, let them enter into our business—let them turn farmers for a few years, and then let them speak with authority: we will confidently await the verdict, and probably we should then have some farmers with a spark of benevolence in them. From a most careful calculation I made last year I found that my men's earnings amounted to about 13s. or 14s. per week, rain or shine. We in no way object to any improvement that can be made in the condition of our men—far be it from us, but would further any good and practical object having that in view; but we do object to those ill-founded assertions, which are almost beneath our notice. But taking leave of these gentlemen, we will now consider the practical relations between employer and employed. We shall, I think, find many errors in each of our systems, accompanied, as a rule, with faults on the part of both master and man. We all, I conclude, acknowledge that there is but one grand rule by which we should be guided, if we desire a successful issue to our undertakings, viz., that one golden rule given to us by the Master of us all, which I have before quoted—"To do as we should be done unto," and by which our actions with each other should be entirely guided. If it were more deeply implanted in the heart of every master and servant, there would then arise a greater reciprocity of feeling, and that mutual interest for the welfare of each which is so absolutely necessary to make all things go pleasantly and beneficially, and which is, indeed, the first and foremost thing required, in order for both parties to reap the reward; this accomplished, we have a good foundation to build upon. If education can do it by teaching those in ignorance what are the duties required of them towards both their heavenly and earthly Master, then "welcome education." For my own part I am not at all adverse to education, provided it is befitting their station, founded upon religious teaching; for without that I believe any education they may receive will prove disadvantageous to themselves and the country at large. If they are not taught their duty to God, how can we expect them to do their duty to man? If no morality is instilled into them, there will be no real moral principle to guide and counteract those evil tendencies of the flesh, which make a man who lacks this great principle feel that it is no matter what unjust advantage he takes of others. We all know the effect upon children if no moral religious principle is instilled into

them; and what will be the result if the whole country is abandoned in this way? I must, though rather out of place, solemnly protest against the wholesale attempt now being made to secularise everything in this country, and bring old Christian England down almost to the level of a heathen land. In bidding adieu to education, I would merely add, I should like to see all our labourers able to read, write, and sufficiently taught in arithmetic to be able to calculate the money due to them for any work they may have done. In the two former they will find something to fill up spare time, which might be less profitably employed; and a knowledge of the latter will enable them to know how to get their due, and remove any ill-grounded feeling of being cheated from their minds, which at present men are very apt to entertain. I trust also education will make them feel a greater respect and regard, not only for their superiors, but also for themselves and their own character—a greater feeling of decency and morality in their every-day life, in which we often find them sadly lacking. In this district we have three principal systems, namely, day work, piece work, and the hiring system. Day work, so called from the men being paid by the day of from nine to ten hours (less in winter), is the system most carried out with us, because they are available in the generality of cases, but it is one fraught with evils, the greatest in my opinion being that we pay men by the day instead of according to their worth. I call it a degrading system, calculated to reduce the best man to the level of the worst, and to bring them again lower, having a continually degrading effect. As an able-bodied, industrious, trusty, persevering man, with a good head upon his shoulders, able and willing to turn his hand to anything, is only paid the same amount as an idle and slothful labourer who does little or no work. This, I consider, a system the very reverse of the one we want to instil, and one that must have a great tendency to keep down the price of labour, because rendering it of so little worth. We want a system that will cause emulation, a striving each one to do his best, with a knowledge that his efforts will be rewarded. But how is this to be attained? I confess I know not the remedy. Individually I believe nothing can be done except in exceptional cases, and collectively it was a great undertaking. Could any kind of class system be introduced? I am fully aware that the opposition to any great change would be great, but I most sincerely wish some system better than the present might be found. Some, perhaps, will say meet it with piece or task work. But this you cannot entirely do. You may in many cases, but not wholly. There is a good deal of work to which you cannot conveniently apply it, particularly during the winter half of the year; but on the whole, I consider it a more equitable and advantageous system than the former. It has the advantage of enabling the master to apply his labour most profitably to himself, and of giving his men the chance to earn what they can, thereby paying them according to their worth, and rewarding the best. Taken on the whole, when available, I consider it far preferable to the day system. We come now to the hiring system yearly and monthly. In our own immediate district, where we lack cottages, the former is the only system we can with safety rely upon, as far as regards carters, shepherds, boys, and all having charge of stock, because without it, when summer comes, we should often be left in the lurch, as we constantly prove; but it is full of evils, one of them being continual change, an almost complete revolution year after year, which would seldom be thought of were it not for Michaelmas. No sooner do the master and servant get into the knowledge of each other's ways, and the latter to understand the master's methods and his land, than Michaelmas comes and unsettles all again, and generally the same thing occurs year after year. But where we lack cottages there is also the greater evil consequent to lodging six to eight or ten boys and young fellows together, free from all restraint from their parents, and, as the law now is, almost all from their master. You may get the greater proportion of these steady and well-intentioned, but the chances are you will get at least one bad one, and, as we know "that a little leaven leaveneth the whole lump," so we may easily imagine that one bad unprincipled servant amongst them will have the consequent ill effect upon the others; and this I conceive to be one reason why the relations between the employer and his hired servants are so often unsatisfactory. Were it practicable with us, and could we feel assured of being treated fairly, I should prefer the monthly hiring system, month's wages, month's warning; but this will not do; the generality

who have tried it will find the servant generally does it with the intention of taking an unfair advantage when summer comes. Another evil attendant upon the hiring system is, I consider, the way in which we hire; it is a perfect lottery. You go into a fair and hire several servants of whom you had not the slightest previous knowledge, or they of you. How can the generality of cases be expected to turn out well? Certainly you make an application for character, but how vastly you get deceived even in that! And coming to characters I wish it were made incumbent upon all masters to give all their hired servants, whether good or bad, upon leaving, a just and written character which they must produce on seeking another situation. We should then have them more mindful of that inestimable thing, a "good character," and should be enabled to choose those likely to suit, added to which those of bad character would be the sufferers. Some, perhaps, will raise the objection that these would not produce their written characters; if not, we could speedily guess the meaning of it. Having entered thus far into this question of labour and its faults, let us consider what are likely to be the remedies. First and foremost on the part of the landlords, I think it is absolutely necessary that they should provide a sufficient number of good cottages, on or in close proximity to each farm for the labourers working on it, to be let with the farm. This must, I believe, be the first step. The men would then be near their work instead of having to walk a mile or two every night and morning (one of mine formerly walked seven miles every day to and from his work), and would also feel a greater interest in that farm, being on the spot. The master must endeavour to do justly (kindly and fairly, and yet firmly) to all, showing no unjust favour, willing to pay his men their full value, ever remembering "The labourer is worthy of his hire;" be punctual in the hours of labour (as a failure in this respect is not only unjust to his men but also to his neighbours), and take that interest in the welfare and prosperity of his men, which is his duty; by so doing he will do his part in endeavouring to establish that good feeling and understanding which is so necessary for the welfare of each. Till this is accomplished things will not be as they ought. The men must also on their part endeavour to do their duty, and make it worth their master's while to pay them well, showing a desire to do their best on all occasions, feeling it their duty to consider their master's interest and welfare in all things—their general indifference to the interests of their masters and distrust of them being, I believe, one of their greatest faults. They must also remember that it is written in Scripture, "If a man will not work neither shall he eat." There appears also to be an entire lack of forethought or any provident spirit in them. Could we only get a better state of things accomplished in this respect, we should then remove one of the greatest drawbacks and blights to farming in the present day.

Mr. DARKE opened the discussion by reading certain resolutions adopted at the meeting lately convened at Willis's Rooms, at which Canon Girdlestone was present. He believed such movements as that set on foot by Canon Girdlestone would fail in securing the object in view. He regarded Mr. Frampton's suggestion with reference to the classification of labour as a very practical one; but there would be difficulties to be overcome in carrying out such a system. For instance, some labourers might be disposed to say they would not trouble to do much because they were not placed in the upper class. Piece work had for years been considered most satisfactory in Norfolk. Hiring had a strong hold upon people in this district, because it tended to cheapen labour. The interference on the part of the public with such matters as Canon Girdlestone had taken in hand would, in his (Mr. Darke's) opinion, drive capital from the soil.

Mr. EVERETT followed, and in the course of his remarks characterised Canon Girdlestone's meeting as a most insignificant one. The parties who took part in that meeting were similar to those members of Parliament who session after session brought forward certain measures, and delivered long speeches, dogmatically stating what ought and what could be done, without knowing in the least degree by reliable information whether their proposals could be carried out by practical men. He believed it was in the power of the agricultural body

to say the annual hiring fair should not be held. Other points in the Paper were also alluded to by Mr. Everett.

The CHAIRMAN also made some practical remarks upon the various questions introduced. With regard to hiring fairs, he conceived that the poor people who frequented them should be considered. Those fairs afforded them an opportunity of meeting together and exchanging friendly words, as they would not otherwise be able to do. There was no reason why such fairs should be abolished because they were abused. If they acted on such grounds they might apply the rule to higher things, and put an end to race meetings, and so forth.

Mr. S. WENTWORTH said that one of the remarks made at the meeting in Willis's Rooms was that they were badly fed. He did not think such was the case, and that their condition would bear very favourable comparison with the state of mechanics and artisans in towns. He felt that as a rule agricultural labourers were better fed, better clothed, and better housed than many mechanics. They certainly had not heard of such distress among the agricultural labourers as had prevailed in the east end of London and other parts of the country. He also believed that there was a better feeling existing between the farmer and the labourer than between the manufacturer and the artisan. Though obliged to hire several servants yearly he should be glad to see the system entirely done away with. If they could go to a register office for their servants they would be able to satisfy themselves much more fully than at present as to the characters of the persons they were taking into their service. If labourers were more provident, and did not come so much upon the poor rates as at present, farmers would be in a position to give more wages than at present. It would be a great advantage if they could induce their labourers to invest what they could in some friendly society, instead of spending their money in the beer-house. He felt confident that anything in the shape of trades' unions in the agricultural districts would be the greatest curse possible to the labourers. He had no fear of that movement extending to the agricultural labourers.

The Rev. C. W. EVERETT considered the remarks made at that meeting showed most clearly that the farmers really did take an interest in their labourers, and if those persons who endeavoured to excite heartburnings and jealousies would inquire more carefully into the things they spoke of, they would find there had been much misunderstanding on the subject.

Several members expressed an opinion that Mr. Frampton had understated the amount of wages paid to agricultural labourers. One gentleman said that in nine cases out of ten in this neighbourhood, agricultural labourers were paid 15s. per week. Another farmer said he had given from 19s. 4d. to 19s. 10d. per week. Mr. James Palmer and Mr. J. G. Wentworth also expressed their views on the subject, after which a vote of thanks was presented to Mr. Frampton, who returned thanks and replied to some of the observations made. The whole of the speakers concurred in complimenting Mr. Frampton upon the able paper he had written, and each expressed their personal thanks for the trouble he had taken in bringing the subject under the notice of the Club.

## TOP-DRESSING SEED LANDS WITH LONG MANURE.

SIR,—This plan of top-dressing grazed seed lands at this season of the year is very much adopted on the thin health-lands of Lincolnshire, as a preparation for wheat. In a dry season, like this, the manure in a few days seems to have become straw in appearance again. If any practical chemist will explain how this mode can benefit either the manure or the land, he will enlighten myself, and, I dare say, many other farmers. The old notion of top-dressing was invariably attended with the idea of the manure being well rotten before being laid on the land. The question is, does this exposure to the sun's rays exhale the goodness of the manure?

Yours,  
August 6th, 1868.

T. B.

## THE FARMER'S FRIENDS AND FOES.

Rooks, congregating as they do in large numbers, and feeding heartily, must exert a very decided influence for good or evil on the labours of the agriculturist; it is, therefore, a question of considerable importance to determine whether these birds are friends, or, as some assert, the farmer's greatest plagues. There can be no doubt that rooks will pilfer newly-set potatoes, will consume the freshly-sown corn, and that they sometimes indulge in the eggs or young of pheasants, partridges, and fowls; but that the balance is decidedly in their favour we consider a fact beyond dispute.

Mr. St. John has very fairly contrasted the amount of good and evil done by the rook: "This well-known bird is common in all this district (Gordonstown), shifting its quarters at different seasons in search of food; and immense must be the supply to feed the tens of thousands which are sometimes seen together. Their usual habits are known to most people; but it is an often-discussed question whether the rook is hurtful or advantageous to the agriculturist. With regard to the mischief done by the rook, the greatest destruction of grain made by it is just as the corn ripens, and before it is cut; where the grain is lodged, and at the edges of the fields, it consumes a considerable quantity, and destroys more. It also attacks the potatoes, digging up those roots which are the least covered with earth. In severe weather and snow it attacks the turnips, and its powerful bill enables it to break easily into the root. It is mischievous also if allowed to attack the stackyard, spoiling the stacks by pulling out the straws to get at the grain. The rook is fond of eggs, too; and in some rookeries egg-hunting becomes their common habit, when, from their great numbers, they scarcely allow a pheasant or a partridge to hatch a brood. This bird is also fond of cherries, strawberries, &c. To counterbalance this long list of evil, for many months of the year the rook lives wholly on grubs, caterpillars, &c.; in this way doing an amount of service to the farmer which is quite incalculable—destroying his greatest and most insidious enemy. In districts where rooks have been completely expelled, this has been seen by whole crops of wheat and clover being destroyed by the wireworm and other enemies which can only be effectually attacked by birds. When we consider the short time during which rooks feed on grain, and the far longer season during which they live wholly on grubs and such like food, it will be believed by impartial lookers-on that the rook may be set down rather as the farmer's friend than his enemy. On close observation, when the rook appears to be following the harrows for the purpose of feeding on the newly-sown wheat, it will be found that it is picking up a great quantity of large white grubs, leaving the grain untouched. Amongst its misdemeanours I forgot to mention one—namely, that in severe weather\* it often digs up the young wheat just as it begins to sprout above the ground. Where rooks or any other birds increase to an inordinate extent, no doubt they ought to be kept down by destroying part of their eggs or young. When the farmer is much annoyed by their attacks on any particular field, a few shots at them soon drives them elsewhere. But very bad would be the effect of entirely banishing them from any district."†

Although rooks do occasional damage, they are often the means of preserving whole crops. The caterpillars of the turnip saw-fly—popularly called "niggers" in some counties—not unfrequently destroy the entire crop of swedes. Mr. Marshall states that on one occasion, when these pests were busy in the neighbourhood, a large piece of turnips lying in an

open field had escaped in a remarkable manner. It lay near a rookery, and was a general rendezvous for these birds.\*

Probably no farm pests more thoroughly deserve the name than the numerous species of the larvæ (wireworms) of the click beetles (*Elaterida*). In the farmer's zoology almost every vermiform creeping thing is a wireworm; but the real wireworms are the larvæ of the afore-mentioned family of beetles:

Now let us hear the opinion of Mr. Curtis, a writer who, from long practical acquaintance with the subject of injurious insects, must be considered a very high authority: "Amongst the birds, that which stands first and foremost in the ranks is the rook. Wary as he is on most occasions, he follows the plough fearlessly, to feed upon the wireworms and other insects, and here his services are most invaluable; for if you dig up the wireworms and other insects, and lay them upon the earth, they will often burrow down and disappear in a few seconds. Many, therefore, of the feathered race have little chance of catching them in the ploughed field; but the form of the bill, combined with the strength and assiduity of the rook, is well adapted for detecting them in their hiding-places. To pick them from the growing crops is likewise the occupation of the rook, when we see him gravely surveying a turnip or corn crop, and with astonishing sagacity selecting those plants only which have a few yellow leaves outside—the sure indication of the presence of the wireworm and other insects."

A gentleman in Norfolk, who well understands the subject, says: "The rooks carry the first tidings of the presence of this formidable enemy by hovering over a field in flocks, and actually pulling up the turnips by the roots to search for them; and I cannot but believe that this sagacity directs them to the infested plants, which are distinguished by their drooping leaves and dark unhealthy aspect."

Again, Mr. Clitheroe thus writes: "In the neighbourhood of my native place, in the county of York, is a rookery belonging to W. Vavasour, Esq., of Weston, in Wharfedale, in which it is estimated that there are 10,000 rooks; that 1lb. of food a week is a very moderate allowance for each bird, and that nine-tenths of their food consists of worms, insects, and their larvæ; for although they do considerable damage to the fields for a few weeks in seed-time and a few weeks in harvest, particularly in backward seasons, yet a very large proportion of their food, even at these seasons, consists of insects and worms, which (if we except a few acorns and walnuts in autumn) compose at all other times the whole of their subsistence. Here then, if my data be correct, there is the enormous quantity of 468,000lbs., or 209 tons of worms, insects, and their larvæ destroyed by the rooks of a single rookery in one year. By everyone who knows how very destructive to vegetation are the larvæ of the tribes of insects, as well as worms, fed upon by rooks, some slight idea may be formed of the devastation which rooks are the means of preventing."

The following is Mr. Groom Napier's list of food found in rooks' crops throughout the year:

January, February, seeds, worms, grubs, mice.  
March, worms, grubs, larvæ, grain.  
April, grubs, grain, seeds, worms.  
May, young birds, mice, insects.  
June, July, insects, young birds, mice.  
August, September, insects, mice, slugs.  
October, November, carrion, worms, mollusca.  
December, carrion, worms, grubs.

That the rook is by no means the farmer's enemy is a lesson our friends in some of the colonies are learning, for live rooks have been imported into New Zealand and Australia, at (we believe) 15s. a pair. Several other boys, also are there in request, which in this country are commonly persecuted with nets, traps, poison, and guns.—*Quarterly Review*.

## CHEAP WATER-FILTERS FOR FARM USE.

Of the growing necessity of filtering water for cattle little requires to be said, and as we progress in our acquaintance with the microscopic world, animal and vegetable, less and less will be needed to turn the attention of the agricultural public to the importance of the subject. In this paper, however, we do not propose going into the physiological question, the construction of cheap filters and the filtration of water for cattle being the topic for discussion.

As in the parallel case of filtering water for towns, two kinds of filters are required—the one a fixture under ground for filtering water into wells and reservoirs, and the other for filtering the water when drawn from such wells, &c., into water-troughs for immediate use. In some cases the former only may be required, in others the latter, and in not a few both; but even when both are required, as in the warm weather of summer, their expense need not put those who require them very much about, if economical means are properly attended to.

The several methods of filtering now in use give rise to a corresponding difference in the construction of the filter; of these three are cheap, and adapted for farm purposes. In the first the water enters upon the top of the filtering medium, passes down through it by gravitation, and is discharged below. In the second the water enters below, rises up through the filtering medium, and passes off from the surface. In the third the water enters at one side of the filtering medium and passes out at the other.

In each of these three kinds of filters there are numerous natural and artificial examples in operation, whose principles of construction and action require to be examined before it can finally be determined what is best to be done in the digging of the well or reservoir, in the conveyance of the water, or in its filtration into the well for future supply or into watering troughs for immediate use.

Where rain water has to be collected into deep wells (surface ponds and stagnant rivers being out of date), numerous examples will be found where such water may be filtered through beds of sand in the subsoil, or be found ready filtered in such beds, if the well is dug in the proper place and to a sufficient depth. We ourselves, in the course of our own individual experience, have met with several examples of this kind on the Oxford and London clays, and also on the Wealden clays of Kent and Surrey, where beds of drifted sand are common; and doubtless many similar instances will be found in other localities. Indeed, most of our spring wells and pumps are familiar examples of this kind of filtration.

These natural reservoirs in the subsoil are generally large basins, which had originally been scooped out in the clay, chiefly by oceanic action. By a similar cause sand and gravel have been drifted, into them at a subsequent period. Over the sand and gravel the subsoil and staple at a still later period have been drifted often in varied strata. Through this upper drift the rain-water percolates, or is filtered into the basin below, where it can be pumped up for the use of cattle directly into watering troughs without any further need of filtering. We have seen an ample supply of water obtained all the year round from a pump-well only about twenty feet deep. In other examples three and four times this depth had to be sunk before water was found. But the expense of boring—an operation which should always precede the sinking of the well—is not great, so that it is easy to determine the actual depth, and into the hole an Abyssinian pump may be sunk.

In some cases, pump-wells of this kind go dry in the summer-time, when they are most needed. In the winter-time we have seen an ample supply of water for the home-stead obtained from a pump; but for a month or two in dry summers it was of no use to the cattle in the pastures immediately adjoining, which were watered by ponds directly over the gravel bed below. How far the bottom supply could have been augmented by boring and allowing a greater surface-supply into the basin below, is a question which we cannot answer, as nothing of the kind was tried. It is only where there is a great thickness of a retentive clay subsoil that the

sinking of water in such cases would be necessary; and, even then, the more advisable course would be to collect the rain-water and filter it directly into a deep well dug in such a soil; for if such a well is dug at the intersection or point where four fields meet, it would supply each or all of them with water.

It follows from the last paragraph, that a dry summer is the best time for boring in search of natural wells of water in the subsoil. The same rule holds good in order to find a continuous flow of spring-water passing from a higher to a lower level by gravitation. Where a series of gravel beds are drifted in basins scooped out in the clay—at different levels—there is sometimes a communication between the higher and lower by means of a thin stratum of gravel or sand through which the water is filtered. Where the flow is continuous all the year round, tapping will procure a regular supply of spring-water; and when the flow is not continuous, it may be drained into a deep artificial well in the winter and spring months, when it does flow to supply the dry season of summer and autumn. In some cases the flow of water from the higher subsoil basin to the lower is so near the surface as to be indicated by the growth of rushes. But into details of this kind we need not go, as in practice they generally speak for themselves in most localities, by the nature of the ground.

When several grass-fields adjoin each other, one well and filter may be made to serve the whole. In some cases one well and filter may serve the whole of the farm, fields at a distance being supplied by means of pipes. Should the well be at a lower level, a force-pump may be required; but if the distant fields are at a lower level than the well, such would be unnecessary. In these latter cases the water may even be drawn from the well on the principle of a syphon, so that by turning a cock the watering trough may be filled. When the farm is wholly dependent upon rain-water, the well must necessarily be on a lower level than the collecting grounds; and between the two levels provision requires to be made for the filtration of the surface-water thus collected by gravitation, which will further add to the depth of the well below the higher grounds. Practically these are simple questions, of easy solution generally speaking; but they require to be closely attended to, as they determine the position of the well and filter.

The size of the well and filter will also be easily determined on the spot. From ponds the amount of evaporation in the summer time is great; but from covered wells it is nil, or next to nil, so that the capacity of the latter would not require to be equal to that of the former. In the winter time the daily influx would be equal to the daily efflux in open weather, and even in the summer time there might be a copious influx at times, so that the difference between the influx and efflux determines the capacity of the well. In the summer time clay soils are thirsty, and drink up all the water that falls upon them; but there are many exceptions, when a large supply could be got from a heavy thunder-storm or continuance of rain in the summer months; and to filter such in the short time allowed, large filters would be required, as a large amount of animal and vegetable matter, in the form of insects, with their ova, seeds, &c., is washed from grasslands on such occasions, unless when the water is filtered into drains through the staple. In short, to filter summer water properly will in many cases be found an expensive process, while the reverse is the case with winter water, for two reasons—first, because the influx is continuous and uniform, comparatively speaking; and second, because the water is nearly free from organic matter in the winter time. The difference, therefore, is very great, in a practical light; for a small filter, in the winter time, would make better work than a large one in the summer time, so that the more economical course would be to build a large underground well, or reservoir, so as to collect and hold sufficient water for summer use, and for such a reservoir a small cheap filter, as subsequently described, is all that would be necessary. To this rule there will, no doubt, be many exceptions, but where farms are wholly dependent upon rain-water and artificial filtration it has much

to commend it to general practice, both on the score of economy and usefulness, when a suitable supply can be obtained free from the organic matter which always superabounds in summer floods.

Filtering material may be either charcoal or sand, or a mixture of the two. The filter may be a long narrow box or drain, built of brick or stone, in Roman cement; or box-tiles might be made for the express purpose, with a moveable lid for each tile. The transverse sectional capacity need not be large to pass a sufficient flow of water to fill a large well in a definite space of time; but as the purity of the water would in some degree depend upon the quantity of filtering material passed through, the length should be considerable. The filtering material should be rammed hard, and the lid forcibly pressed down by a sufficient weight above. The efflux may be upwards from the surface, at a somewhat higher level than the surface of the box, in order not to wash out filtering material. The influx should first be upwards, the better to keep out silt, and to permit washing and cleaning the filtering material in the mouth and throat of the filter by reversing the flow of water at the ingress, and for which provision should be made by shutting off the water from the general body of the filter, and allowing it to flow past the wall altogether during the washing of the ingress portion of it, which may technically be termed the mouth and throat of the filter.

The filter, according to this design, would be composed of three parts, viz., (1), the mouth with the throat; (2), the body; and (3), the vent. The former or ingress portion should be of greater transverse capacity than the body, but it need not be of greater length. The quality of the water will determine the dimensions in both cases. The object of this part of the filter is to remove silt and all matters held in suspension, so as to keep the body or middle portion clean and in successful working order, and so constructed as to be easily washed when it gets foul and does not pass a large enough flow of water. In the majority of cases twice the capacity of the body would perhaps pass the water sufficiently fast. Between the throat and body there should be a sluice for shutting off the water from the latter, and at this sluice there should be an auxiliary mouth for the purpose of admitting water to wash out the foulness which collects in the filtering material that fills the throat. The body and vent of the filter may be of one capacity and piece, the vent or discharge portion being merely a bend upwards for the purpose of more effectually preventing the efflux current washing out the filtering material as already stated. Below the mouth there should be a cesspool for sediment, with a sluice in the bottom for draining off the water during the process of washing the throat. Out of this cesspool stones, gravel, and the like may be kept by a grating, but into minute details of this kind it would be superfluous to go in a general notice.

In examples where cattle are watered from rivers or their tributaries, a small current from such could be diverted into a filter of the above kind, there being a small well at the effluent end capable of holding a sufficiency of water to fill the water-troughs.

When tributaries cease to flow, in the warm weather of summer, as they often do, a large well would be required for this period; and it should be filled in the winter season. In some places bottom-water is abundant at a short distance below such tributaries, either in rock or gravel, from which a plentiful supply, naturally filtered, could be obtained at all times by means of a pump-well. Such examples are numerous; and it is truly humbling to see cattle forced to drink out of the stagnant pools in tributary streams, green and thick, and stinking from decaying animal and vegetable matter, when fine pure water could be got in the middle of the field, under twenty feet below the surface, in a few minutes, by the American tube-well and pump? That the proposition would pay is already proved by experience; for we might quote numbers of cases where pump-wells and draw-wells have now been in use for many years, and where the value put upon them falls little short of the rent of the land. In point of fact, practically speaking, the pastures without them would be worthless to any farmer or grazier.

When the filthy water of rivers has to be stored in a well or reservoir, a second filtration of such water would often be necessary; and the second filter may require to be a moveable one, either at a distance from or adjoining the watering-trough. In this respect the filter and process of filtration

would resemble in principle those now in use by some dairy-men and private families in the Metropolis and other large towns. In those examples which have come under our notice the filter is placed between the cistern filled by the water company and the watering-trough of the dairyman, or a second cistern for holding water for the use of the family, cows, and horses.

In these examples the filters and processes are patent ones, the peculiar filtering material occupying a portion of the water-pipe, so enlarged as to hold it. In principle there is, however, nothing patentable in the mechanism of such a pipe; so that any country carpenter who can make a watering-trough can likewise make a cistern and a filter. Thus, if a water-butt is placed at one end or side of the watering-trough, the filtering material may be placed in the bottom or lower portion of the barrel or butt, so that the filtered water could flow into the watering-trough. All, then, that the cattle-man would have to do in his daily rounds, under such conditions, would be to fill the water-butt, either by a pump or with a bucket from a draw-well. Should a simple filter of this sort not prove sufficient to purify the water, another plan may be adopted by placing a long filtering-box under the watering-trough. In this case the water-butt or cistern may be at one end of the watering-trough, as in the previous example, the vent or discharge-pipe being at the opposite end. The bottom of the watering-trough may be the lid of the body of the filter, which would be similar in principle to the underground one already noticed, only wanting the throat, for which there would be no use, so to speak. The watering-trough may be of the same length as in ordinary cases, so as to permit of an equal number of cattle drinking at the same time; but it may be of less depth and breadth, as the process of filtering from the cistern would keep up a continuous supply of water. The expense of such a filter, therefore, need not be a deadly sun, if common-sense economy is at all attended to in its construction. Instead of being adjoining each other, the cistern-filter and watering-trough may be placed separate from each other, and in some cases the water from rivers may be filtered directly into the watering-trough, at a lower level than the head; but into the great diversity of such details which practical circumstances may suggest we do not enter.

X. Y. Z.

## THE DUBLIN HORSE SHOW.

This show was opened on July 28th, under the auspices of the Royal Dublin Society, which offered £1,000 in prizes. The first prize, £40, for thorough-bred sires, was awarded to Mr. J. M'Mahon, Mountrath, for Roman Bee, by Artillery, out of Queen Bee, by Harkaway; and the second, of £20, to Mr. W. Hatch, Ardee, for Cellarius. In the second class, for sires calculated to get carriage horses, troop horses, or roadsters, Mr. L. M'Court, Dublin, was awarded the first prize of £25; and Mr. W. St. George, Tyrone House, county of Galway, the second prize. For heavy-weight-hunters, Mr. T. Butler, of Ballycarron, was awarded the first prize of £20; and Mr. W. Meredith, of Derryhough, Queen's County, second. In the section for hunters not less than five years old, Mr. D'Arcy, of Athy, received first prize, and Mr. T. Teague, Thomastown, second. The young horses, especially the three-year-olds, were very good, and far superior to the aged hunters. In tracing the pedigrees of many prize winners, it was distinctly evident, from the sire who gained the first prize, down to the mere pony, who so excelled in fencing power, that Birdcatcher blood was predominant. The sires and the young horses formed the prominent characteristics of the show. Some few animals of merit were to be seen among the cobs and ponies. Thirteen hacks and ladies' horses were dismissed without a prize being awarded by the judges. The cart-horse sires shared the same fate, although one of them had won endless trophies in England. The trooper classes did not fill, and may be dispensed with another year. There were several sales effected at remunerative prices. Mr. Hartigan bought Mr. Butler's first-prize weight-carrier for £300, and Mr. Tennant is said to have refused £200 for his light-weight hunter, £400 being his lowest selling price. The horse is certainly a little wonder.

## THE VETERINARIAN VERSUS THE FARMER.

There should be no more useful commentary on the proceedings of an agricultural association than that to be supplied by the veterinary profession. It is precisely the kind of science that should be brought to bear upon a cattle-show. By the exercise of careful observation on such occasions, the Professor should be able to tell us how far the constitutions of animals are injured by their being prepared for exhibition, where the line against excess should be drawn, and how much or how little hereditary disease develops itself in the breeds of stock just at present more particularly encouraged. It is comparatively outside criticism of this order, if ably and boldly advanced, that would carry so much good influence, both with exhibitors and directors; and it is accordingly satisfactory to see in the new number of the *Veterinarian* an article called a "leader" in the table of contents, and "editorial observations" in the body of the magazine, on the country meeting of the Royal Agricultural Society. The paper thus comes with all-sufficient authority, and only the more when we find that the work is conducted by Professor Simonds, assisted by Professor Varnell, both of whom were professionally engaged at Leicester. The premises, as a consequence, could not be better laid, and we turn with some interest to a study of those examinations and deductions which the heads of the College organ enjoyed such peculiar facilities for making; as, indeed, it is not too much to say that from the time the animals were in their places, the Royal Show was at the service of the inspectors. The report—or rather, perhaps, as it should be, at two or three weeks after date, the review—opens promisingly enough: "The meeting has proved in every respect a most successful one."—"The number of persons entering the showyard, and the sums received for admission, place the meeting very high in the scale."—"Bury St. Edmunds is completely eclipsed." And thence we are gradually led on to some consideration of the actual merits of the show: "Subjoined is the award of the stock prizes at the Leicester meeting. Its perusal will show that the several classes were well represented. The competition was strong, and only first-class animals carried away the honours. The show was grand in every division of it. By far the larger number of the horses, cattle, sheep, and pigs, for their purity of breed and beauty of symmetry, were never surpassed, although in some of the classes the entries have been more numerous." And this is all! The prize-list, to be sure, runs to some twenty pages, although, with a little pulling together, it might easily have been included in half as many; and then, of course, we have the old absurd excuse that "Our space will not allow of individual, or even class criticisms, to be made. Indeed, where all was so good, there is little occasion for this being done, and more especially in a journal like ours, which is devoted more immediately to the science of medicine than to the science of agriculture." The latter part of this paragraph is really rich; for what in the world is the use of the science of medicine—of veterinary medicine as here implied—if it be not brought to bear upon the science of agriculture? What is the use of the Royal Agricultural Society paying so much a year to the Veterinary College, and so much in fees and expenses to the veterinary professors, if their science is to be so religiously kept to themselves? As well might Professor Voelcker say that the science of chemistry is not the science of agriculture, and that he must therefore decline

to offer any criticism on individual experiments or class kinds of cultivation. An improved beast is as much an experiment as a new manure for turnips; and before we go too deeply into one or the other, it may be as well to hear from science how far we should be justified in doing so.

The *Veterinarian* has not "the space," nor does it see the "occasion," for offering any such advice; but if the *Veterinarian* can tell the farmer nothing about his stock, it can tell him something about himself. In this very paper, on the country meeting of the Royal Agricultural Society, the editor, with even so little space at his command, can still find room to say that "Farmers themselves, as a body, are woefully behind the rest of the community. The views of many are so contracted that they only look upon an animal out of health as of a plough out of repair." Taken singly, and bearing in mind the quarter from which it emanates, all this can be regarded as little less than impertinence; but it may be as well to ascertain the reasons given for this wholesale attack, made under cover of the Royal Agricultural Society. Farmers, then, are woefully behind everybody else because "much more is needed to give a status to the veterinary-surgeon in rural districts. His means of living are frequently frittered away by the cowlceech and the farrier, and often he receives but little assistance from the resident members of the Society."—Because "these men (the farmers) are the supporters of cowlceeches and farriers, and ever will be until they become better informed;" and so on. We shall be very ready to join issue here, and be quite content to take the Professor's own words in doing so. The veterinary surgeons, then, are as a body woefully behind the rest of the community. The views of many are so contracted that, beyond the horse or the dog, they look upon any other animal out of health as a plough out of repair, and know no more about mending it. Again, we say very emphatically that much more is certainly needed to give a status to the veterinary surgeon in the rural districts. Let us only turn to the history of the recent cattle plague, and gather from this the gross ignorance and hopeless incapability of the veterinary surgeon, not merely in the rural districts, but in our cities and large towns. "The Royal Society," says the *Veterinarian*, with a sort of patronizing encouragement, "has much work before it, and it must keep its shoulder honestly to the wheel. It has laid the foundation of a better education of the farming classes, and year by year it must build thereon." If the Royal Society should keep its shoulder honestly to the wheel, and if it continue to vote grants to the College, we do trust that the Council will try to get something in return, and at least endeavour to lay the foundation of a better education of the veterinary classes. The experience of the last three or four years has shown nothing more shifty or unsatisfactory than the action of the V. S. over the diseases of cattle, and the paper we have under notice comes well in point of such theory and practice. The writer, who appears to have been at Leicester, cannot find space for individual or even class criticisms on the stock, although he can manage to find plenty of room for criticism on, or a rather unwarrantable abuse of, the exhibitors. "Know thyself!" says the old Greek proverb, and ere the *Veterinarian* begins to talk too fast of the farmer being so woefully behind the rest of the world, let him look at home.

Professor Varnell, if we remember aright, is in the

habit of supplying to the *Journal* of the Royal Agricultural Society a brief but pertinent paper on the horses which come under his notice at the annual Show; but is there any companion article on the cattle classes? If not, care should be taken that Professor Simonds do not

languish from any lack of space. Mr. Bowley, as the senior steward of stock, has, we are glad to hear, determined to dispense with any wretched cobbling, and to prepare the Report himself; and to his attention we commend "the science of medicine."

## OUR GRASS LANDS.

Is the management of our meadows and pastures keeping pace with the progress of things? Practically speaking, the question is a plain one, meadows and pastures each returning its own significant answer in every province and corner of the kingdom; and, although there are many praiseworthy exceptions to the general rule, the general rule itself, we fear, must be pronounced a negative answer to the question. At all events, there is much room for improvement in this important branch of farming.

Seasons develop their own peculiarities in our natural meadows and pastures, and the present one is no exception to the common rule. It is highly interesting to examine grass lands at any season of the year, as to how the different grasses are being affected by the weather; but about the middle of May it is doubly so, owing to the stage of growth the various plants have attained—more especially in meadows that have been laid out for mowing and yielding hay. To the superficial observation of the mere passer-by, this or that field may appear different from what it does in the eye of the farmer; and there is perhaps no other branch of farming in which farmers themselves see things so differently as they do in their meadows in the month of May, and in which experience confines their knowledge to their own individual farms and neighbourhoods, owing to the normal peculiarities in their geography, geology, and botany. True, all are familiar with the proverb, "It is May that makes the hay," and also with the facts on which this old proverb is founded; but a more extensive knowledge than this old rule involves is needed to examine grass lands at this season with a view to determine whether or no they are keeping pace with the times.

At first sight, the question for solution is no doubt one in physiological botany relative to the kinds of plants growing, their health and constitutional vigour, together with the progress which this or that class of plants have made and are making towards maturity, and how other classes of plants have fallen or are falling behind in the competitive struggle for subsistence. When a litter of young pigs falls to sucking, each laying hold of its own teat, it does not require a very deep acquaintance with natural philosophy to comprehend the propriety of the whole, and how useful it is for a prolific sow to teach her offspring the regularity they so conspicuously preserve, in order to enable her to give each its own fair share of the means of life. The example is homely but familiar, and full of characteristic truth; and, although plants are said to suck old Mother Earth in a somewhat similar manner, yet in the meadow there is no such regularity preserved as in the pigsty, the vegetable family being obviously fighting a pitched battle for the supremacy in the majority of seasons!—a state of things which ought not to be (P).

Fairplay is a golden rule, no less in the vegetable kingdom than in the animal kingdom; and when farmers see weeds and inferior grasses milking old Mother Earth dry, thereby leaving the finer kinds of grasses to starve, other questions than botanical ones introduce themselves for solution. There cannot be two opinions as to the golden rule being equally applicable to both families, the animal and vegetable. The difficulty lies in the education of the latter—the grasses; and as that difficulty disappears in rich meadows, where the finer grasses all grow luxuriantly, to the exclusion of weeds and even the inferior grasses, it affords a key to the solution of the question.

The practical and progressive question hinges upon the normal dietary of different plants. Thus, when the farmer sees weeds growing luxuriantly in his meadow, and the finer grasses every day becoming more and more sickly, and that this state of things is in a greater or less degree peculiar to the season, or to some specific mode of management, he concludes that what would otherwise have been the food of his finer grasses has become the food of weeds—that the land,

under existing circumstances, is adapted for the growth of the latter, but has become inimical to the production of the former; and as this general conclusion is fortified by the facts of the case, so far as observation can determine, the physical data by which such results are produced resolve themselves into secondary questions relative to the nature of the improvements requisite to effect a healthy state of the land in like seasons for the future.

Much diversity of opinion yet exists amongst farmers relative to the conversion of partially-fertile meadow-land into a permanently-healthy state, analogous to rich meadows over which the vicissitudes of seasons have little or no influence beyond the mere weight of crop, some arguing that judicious manuring will make up for all natural deficiencies; others advocating drainage, or the admixture of soils not usually included under manuring; while a third class believe in nothing else but the breaking-up to aration all such lands that are not naturally adapted for lying permanently in grass, without deterioration, beyond what can be supplied by manures in the ordinary way. To enter upon the details of the several plans thus advocated is far beyond the limits of a short paper like this, all that we can do being to turn attention to the several lines of argument, viz., the manurial theory, the admixture of soil theory, and the aration theory.

That manure will cover many faults is a truism which may safely be granted; but those who have annually to pay long bills for artificial manures have long since arrived at the conclusion that before such manures will pay, the land must be in a proper state to receive them; and our practical readers will perceive how seldom this rule applies to a very large area of the grass lands in question, whether they are in meadow or pasture. No doubt in wet seasons artificial manure may be applied in a dry form, and in dry seasons in a liquid state. But such reasoning amounts to nothing more than fireside farming, more especially if the staple and subsoil are both mechanically defective; for if either or both are so, then the solution of the question is not a manurial one, apart from the pounds, shillings, and pence problem at issue.

The proposition of laying clay, sand, gravel, chalk, and the like on some grass lands to give them a permanent richness of fertility, although it has proved very successful in many cases has failed in others, and for obvious reasons—sometimes mechanical, sometimes chemical, but more frequently both. That the practice has much to commend it, is almost too manifest to require acknowledgment; but to lay it down as a general rule is beside the question. It is even more limited in its application than the manurial theory. It will no doubt be said, in reply to the comparative question thus raised, that the admixture of soil theory is only intended as an adjunct to the manurial theory, and doubtless both theories thus conjoined are of more general application. But granting this, they nevertheless fall short of supplying the mechanical requirements of such grass lands.

Such being the shortcomings of the first and second plans, viewed either severally or conjunctly, it naturally brings us to the third line of argument, viz., the proposition of the plough, or rather all the three plans conjoined, for the mere breaking-up of such grass lands to aration would not of itself solve the practical problem at issue. And we need hardly add that the advocacy of this conjunct view of the subject is becoming more and more general as we progress in chemical and mechanical appliances. More practically viewed, the permanent improvement of such grass lands resolves itself into one of profit; and thorough drainage, artificial manures, improved implements, and the application of steam-power to all agricultural purposes are rendering the breaking-up of such grass lands to arable husbandry more profitable than before their introduction.

NEMO.

## THE CLOVER CROP.

There are few questions connected with agricultural practice which give rise to more interesting research than the peculiarity so frequently observed respecting the growth of a second cutting of clover, and its influence upon the succeeding corn crop. The speculations which have been advanced, and the explanations which have from time to time been given, appear to contradict so many well-established opinions, which have generally been accepted as undeniable, that the question still appears shrouded in mysterious doubt. It is held, and we see no reason to deny its accuracy, that any crop grown upon the land, which may be cut and carried away, must of necessity have a tendency to impoverish the soil from which it is produced. It is true, that if such produce be removed to the homestead or fed off, upon other land, the farm remains uninjured; for this process then simply resolves itself into a transfer, from one part of the farm to some other portion, of a bulk of vegetable matter, which being consumed by stock, is partially appropriated by the animals feeding thereon, and the residue again reaches the soil as manure. The peculiarity so frequently noticed in the growth of clover chiefly consists in the act that land from which a second crop of clover has been cut and carted away, is in better condition for the growth of wheat than when the same clover is consumed upon the field on which it is grown. Indeed we may go so far as to say that even when such clover has been allowed to stand for seed, it is not uncommon for the same result to be observable.

This, we readily acknowledge, conflicts sadly with many established rules of agriculture; but these facts are none the less correct on that account. It is placed beyond all doubt, that the removal of a crop of clover—and still more so with a crop of clover-seed—must of necessity withdraw from the land much valuable fertilizing matter; and it follows as a natural consequence that the soil cannot be as rich in fertilizing ingredients as it was prior to its growth. And yet we have the paradox existing in the shape of an improvement in the crop of corn upon that portion which has had the clover taken away, as compared with that part on which the clover was fed on the land; or in other words, a diminished degree of fertility is attended by an increase in the crop of corn.

It is clear that there must be some compensating influence to explain this result. It has been maintained by many that when the land is depastured there is a considerable exposure of the soil to the scorching influence of the sun, and thereby the nature of the soil is said to be drawn out and its quality injured. We have little opportunity of knowing what is really intended by this explanation, and, indeed, it can only be received as exceedingly indefinite. It is easy for any one to understand that manure exposed to the sun may lose some portion of its volatile constituents; but we have no corresponding loss taking place by the action of the sun upon the soil—so far, at least, as any trustworthy researches have hitherto led us to believe.

We must rather seek for an explanation from some other influence more definite in its character, and more capable of accurate proof. In the luxuriant growth of clover we have one of the best illustrations known, in the entire scope of agricultural practice, of a crop gathering nutriment both from the soil and from that which is the common property of all—the atmosphere above it. Its roots penetrate into and through the soil, gathering

therefrom the nutriment the crop requires, moulding it into new forms, and preparing it for being assimilated in the growth of the crop. This vigorous growth below the surface is accompanied by an equally luxuriant development of foliage above, which very powerfully co-operates in promoting the general increase of the crop; the activity of the roots has a fitting counterpart in the vigorous action of the leaves, which abstract from the atmosphere much valuable fertilizing matter; and thus, by the co-operation established, we have an accumulation of a rich mass of vegetation, valuable either as food or as manure, but its growth has been the result of an active development both above and beneath the soil. Any circumstances favourable for promoting vegetable growth would in such a case act favourably; and, on the other hand, any condition unfavourable thereto must tend to diminish the produce.

If we now notice the growth of a crop of clover which is being depastured, we shall observe that many of the conditions of luxuriant growth are wanting; and, as a consequence, we cannot have an equally extensive formation of vegetable matter. The irregular manner in which such clover is eaten not only destroys much valuable food which has been produced, but by the sheep eating into the centre of the plant its further growth is frequently effectually stopped, and thus much of the clover perishes, and leaves the soil exposed and in an unproductive condition. Further than this, the crop has no opportunity of making a bulky growth, the practice being generally to eat it as it is growing, rather than let the crop advance towards maturity, and then be fed off.

It is in the latter stages of growth that the two practices offer the greatest contrast. When a moderate growth has been secured, the one portion may be set aside for feeding, and the other part reserved for mowing; but, from this moment, the one is subjected to a process of a destructive character, and the other is permitted to accumulate, with a constantly increasing force, vegetable matter of the richest character. Instead of the plant being plucked in its point of growth, the development goes on uninterrupted: the soil, instead of being scorched by the rays of the sun, is kept moist by the overshadowing leaves of the clover crop, and thus the growth of the crop is encouraged. The growth, and consequent accumulation of rich vegetable matter, goes on until the period of full-growth has arrived, and then the whole is cut down and removed. In the one case, the growth is interrupted during its most important stages; and, in the other instance, it is encouraged with its fullest luxuriance.

It is perfectly clear that by such a luxuriant growth the demands upon the soil have been very greatly in advance of that removed from the soil by the portion fed upon the land; but we must not lose sight of the fact that the growth above the ground has been proportionate with the growth of the roots in the soil, and that a luxuriant crop of clover leaves such a rich legacy for the succeeding crop in the accumulations of vegetable matter produced by the decay of the clover roots. When the crop has been fed upon the land the growth of the clover root has been impeded, and consequently the land is far from being in equally good condition for the growth of corn. True, we have removed from the land a considerable quantity of valuable fertilizing matter in the clover taken from the field; and yet, by the course of manage-

ment pursued, there remain behind in the soil accumulations of fertilizing matter of a different nature, but most valuable for the succeeding corn crop, which more than compensate for the loss. The advantages appear all on one side, for most remains where most has been removed; but in the one case we have secured an uninterrupted and luxuriant growth, whereas by the process of feeding the clover we have kept its growth impeded, and consumed it in such a manner that the land could not receive those stores of rich nitrogenized matter which the clover extracts from the air and adds to the land.

It must be admitted that there are exceptional cases to the more general rule we have referred to; but those

variations may generally be shown to be traceable to other causes, and not in any way to interfere with the rule. If, for example, the plant is weakly in its character and habit, or has partially failed upon the land, the difference in favour of cutting will be less evident; the closer and more abundant the crop may be, the more fully will the result be in favour of mowing as compared with feeding; and conversely, when the crop gives no evidence of growth, we ought not to look for results of as favourable a character as we should otherwise expect. The secret of the entire difference lies in the fact of an uninterrupted growth being encouraged until the fitting time arrives for its prompt removal.

## THE NEW FARM.

I must—botheration!—but yet I must, despite the depressing effect of this fearful electrical weather, for I have promised that I will write. I really hope that at last the sky has arrived at its bursting period, for there has gathered during the evening right above the house a most matrimonial-looking thunderous cloud, which I think must needs come down about curtain-time. What a thing it would be to be young again! Even at this sultry irritating moment there is a merry noise from the roost of the youngster boys, who have bolted the door against the remonstrance of the only party they fear, their eldest brother, and are throwing nude somersaults about the nursery floor. The hand-maidens are weary, and only feebly expostulatory, for we are going to have a “leetle” dancing party, and they have been hard at preparatory work all day. Oneself is angry, but tied heretofore, so that the juveniles have a fair prospect of being ultimately triumphant. Even as I write, however, there is a consternated close cry of “Eliza! Eliza! Eliza-a-a!” as the shrewd attendant hath turned the light off, and plentifully applied “cold pig.” Pig! that recalls one to the farm again, and the thought of water, too, is suggestive. I have been the main part of this day with a home-made implement tapping weak spots, in anticipation of a Norton’s pump, that I expect to arrive to-morrow. We have repeatedly struck water, but as repeatedly been stumped out. There is

“Water, water everywhere,  
Nor any drop to drink.”

We strike a sandbed, and the mixture chokes the valves. We draw forth the pipe by dint of lever, empty it on its head of a good thick sedimentary gallon, replace it in its hole, and, still most obstinate, it refuses to yield water. The pulling up and down hath made a puddle of the sides, and again suffocating results! Then we get dismayed and despair of gaining our object from this slough. So we strike down a crowbar anew, and come thud thump upon a rock, a soft sandstone layer, through which we drive the bar without much difficulty; and then underneath occurs a bed of marl, which fills the perforations of the pipe; and so we are effectually done, as we have no further length at hand. There is no alternative but to desist, and await the arrival of the genuine article by rail from the Birmingham agents.

Here we left off last night, it being positively too painfully sultry to get on with one’s writing. Hand and arm absolutely stuck to the paper, as our ideas stuck resolutely, too, in the clay pocket of our muddled brains.

But, as the Irish song says,

“Twas of a Wednesday night,  
At two o’clock in the morning,”

when, glad sound, through the open window! there was a

torrent descending. Good-luck now for the embrowned pasture, good-luck for the mildewed swede-leaf, good-luck for the farm *in toto*; for now, at this hour of 9 a.m., a mist—quite a washing-day mist—covers the face of the whole earth; and there will be a luxuriant growth forthwith. With our abundant, sweet straw, there may not, after all, be a dearth of cattle-food, supposing—as there is every present prospect—that we can put in the breadth we intend of hybrid turnips.

There is an excellent plan of quaint old Drury’s for the multiplication of food, the secret of which consists in soaking wheat-straw. I cannot lay hands on his work just now; but, if I remember well, his plan was to cut wheat-straw of a short length, and then put it to soak for some hours in cold water until a thick mucilage be formed. He then boiled it, stirring in a portion of meal. By this means he was enabled to keep a large extra quantity of stock. I must look the volume up, and give his exact words next time.

I have just been called off to inspect a useful new implement which I bought at Leicester, and which, wonderful to relate, satisfies my honest, ruddy-faced old bailiff. It is an ordinary but excellent plough, which, by the simple alteration of three bolts, can in a few moments be converted successively into a potato-raiser, a digging implement, a subsoil plough, a paring plough, and a double mould-board plough.

Having stumbled upon the mention of the Leicester Show, let me thankfully acknowledge what a wonderful opportunity for successful study both of animals and machinery that tented field afforded to the young farmer. From the shilling knife-sharpener and linen-wrapped refrigerative dish-cover to Howard’s monstrous moorland plough and Owen’s cataract-pump, there was something at every step to attract and instruct. The Southdown ewes were lovely as ever, with their quiet grey eye and weighted thigh. The snowy Cotswolds were a picture, yet suggesting to one the involuntary thought that the loss of one such individual must be heavy, and that, considering the precarious life of a sheep, I should prefer meeting my luck with four small representatives of the ovine species to staking so many sovereigns in a single specimen. There were some grand Herefords, amidst others of vulgar quality. There were delicious-looking Devons and a sweet first-prize Alderney heifer, that capered about in her owner’s hand as if triumphantly exhibiting her rosette in gratitude for the indulgence her early youth received at his hand; but after all, for numbers at least, the Shorthorns had the pull of the show. Of the professional critics there were some who considered this the best show upon the whole of such kind ever exhibited; there were others who compared it disadvantageously in

their mind's-eye with the exhibitions of past years; but I must say, in accordance with a very general conclusion of the practical-farmer-tribe, that the fallow period, owing to the cattle-plague, if it have produced no wonders, has heavily accumulated a grand store of the breed. Lady Fragrant, with her immense frame, her very table-land of back, her great udder, and most sweet feminine front, is (deny it who can) the very perfection of a cow. In old time we have seen others more tubular and beef-suggestive, but we have never seen a cow before displaying in so high a degree the characteristics of the milking cow, with fattening promise for the period when the lacteal produce naturally shrinks.

Again, was it not astounding to see Commander-in-Chief (who in his stall showed a head too ox-like and a tail too high) in the exhibition ring draw himself up, and magnificently look around him with an air that reminded one of old Comet's picture, and which at once placed him first amidst a numerous assemblage of superb old bulls? It was the sight of the show to see these veterans pace round—rich roan, red, or white.

We were all glad to find so eminently triumphant the breeding skill of that rare old man who was so hospitable at Warlaby, and we heartily trust that his mantle has descended on his nephews. I must not omit to give his

due meed of praise to the retiring, quiet-mannered youth who had charge of these cattle. A more obliging, civil, unobtrusive lad I never met. His manner in the ring too was a lesson to others. There was not on his part, as on the part of others who repeatedly made the by-standers indignant, the kicking back of a beast's hoof, the jerking-up of his head into some pet position, nor was there the repeated grotesque lugging forth of his charge before the judge's eyes even when his turn for inspection was past, and the claims of other animals were being fairly investigated. He left his animals to exhibit themselves with their natural elegance, and accepted his fate accordingly.

The great number of new names intermixed with the old ones shows how the breeding taste is advancing, even as is an inclination amidst the wealthy for mowing-machine and steam-plough.

My paper having come to an end, I would only use the few last lines to remind the beginner that if he wishes for real satisfactory success in the end, he should climb as far as he can upon other's shoulders to begin with; that is, he should buy only animals of the best of pedigrees and the best of shape, an opportunity which is offered him by the continually advertised sales of famous breeders, who are either overstocked or have fulfilled their term of years.

VIGIL.

## GEOLOGY, BOTANY, AND CHEMISTRY.

At the last quarterly meeting of the Logie and Lecropt Farmers' Club a paper was read by Mr. Henderson, Stirling, on "What Geology, Botany, and Chemistry have done for Agriculture."

MR. HENDERSON said: Whether agriculture is denominated an art, a science, or a profession, there is at least one point on which I think most people will agree in opinion, namely, that in the practice of agriculture, as at present carried on in this country, a knowledge of many of the arts and sciences is advantageous to the agriculturist. I do not know of any other branch of industry, in the prosecution of which the attention requires to be devoted to such a variety—such a multiplicity of subjects as that of the agriculturist's; and I do not know of any one science or art which may not occasionally be useful to him in the exercise of his calling. To become a thorough practical agriculturist requires from an individual a very considerable portion of time to be devoted to the acquirement of the requisite skill, and acquaintance with minute details, in addition to the knowledge of general business. It is, therefore, out of the question that the man who has to earn his bread by the practice of agriculture can be able to devote the period of time necessary to the acquirement of every science and art bearing thereon, so as to become a proficient in each; in fact it would be equivalent to his becoming an adept in all the details embraced in the whole range of arts and sciences known to man. In other branches of industry there are greater facilities for a division and subdivision of labour, both mental and physical—thus enabling individuals to concentrate their energies on one subject, and so to attain to greater proficiency, skill, and expertness, in their particular callings. Although the agriculturist may have a general knowledge of the arts and sciences, I think it is advisable that, in all important matters requiring scientific research, he should have recourse to the professional man, and not depend on deductions which his own acquirements in science may enable him to make, as these cannot be so reliable as those of the man who makes the subject his daily study. In making use of the words geologist, botanist, and chemist, in the following remarks, the terms are meant to apply only to such persons as make the study and practice of the respective sciences the business of their lives—men learned and practical in their own professions, but, it may be, mere theorists and outsiders in so far as agriculture is concerned. For instance, put a purely scientific man to stock and manage one of your farms, give him the best of labourers to carry out his instruc-

tions, but withhold all practical advice and assistance, and the results would probably be more awkward than the first attempts of the ploughman with the hammer of the geologist, the portfolio of the botanist, or the retorts and crucibles of the chemist. Permit me to use the word agriculture, not in the restricted literal meaning, but in the broad sense, as that industry employed in the production of what is embraced in the bold comprehensive saying of "horn, corn, wool, and yarn"—with the substitution of some such word as esculent for the latter. I believe the technical definition of the word agriculturist is, "He who follows agriculture as a science;" and of husbandman, "He who devotes his attention to the tillage of the ground and management of cattle." I am taking the liberty to omit these distinctions, and to include all who employ skill and capital in this branch of industry under the term agriculturist; for it is evident these technical distinctions are not very applicable at the present time, and it is not necessary for our purpose to enter into elaborate details. Keeping these preliminary observations in view, I would now proceed to make a few random remarks on what the science of geology, botany, and chemistry have done for agriculture. The first mentioned is geology. There is some difficulty to discover much direct benefit which this science has yet conferred on agriculture. Our country is beautifully diversified with hill and dale, with ravine and glen and valley, with loch and stream and river, and is bounded by the ceaseless ocean. Geologists inform us it was not always so. I do not think they give a description of the appearance of the world before their fancy began to play upon it, but they tell of upheavals, subsidences, dislocations and fractures of the crust of the earth. They tell how these convulsions, with the combined actions of fire, and frost, and snow, and ice, and springs, and wind, and rain, and running water, and the ocean's tidal wave, have scooped out the bed of the loch from the solid rock, formed the ravine, the glen, the valley, and the course of the river. They tell how these forces are still in operation, slowly but surely crumbling down the rocks; the little rannel from year to year eating deeper and deeper into the mountain's side; the stream still cutting and deepening the ravine, and carrying the debris from the higher to the lower grounds, or into the sea beyond. They give much information about the district in which we reside—how the rich and fertile valley was once a sea bottom; how the stern rocks of the Abbey Craig, Stirling Castle, and Craigforth have withstood many denuding agencies, and still remain, giving beauty

and romance to the district, while other rocks of softer substance have been dislocated, fractured, worn down, and great part carried away, leaving only a portion of sediment, which now forms the rich earse lands stretching so many miles both to the east and west of these rocks. Geology gives information as to the deposit of alluvial soils and moraines, and although, strictly speaking, not altogether a geological question, of peat moss, its growth, and unexplained decay in some instances. But what is more to our purpose, geology gives much valuable information about the existing surface of the earth, and has minutely classified and described the various kinds of rock of which the crust is composed, and furnished maps on which the different formations of rock are delineated. These maps are no doubt subject to much improvement, and it is to be hoped no long time will be allowed to elapse before they are corrected and published in a form in which more minute details will be given. But even as they are, much useful information may be got by a careful perusal of them. By examining one of these geological maps, the agriculturist can ascertain the variety of rock prevailing in any district, and in the majority of cases the geological formation of any estate, or particular farm; and can thereby form a more correct opinion of the quality of the land—the general characteristics of the soil—and the kind of crops it is most suitable for producing. Where alluvial or other deposit exist, the above cannot apply, but in upland districts and on declivities the case is different; there, in general, the soil has been formed from the denudation of the existing description of rock, which may either be in a projecting or subjacent position; if in the latter, the nearer to the surface so much the more correct are the indications to be obtained by geology of the nature of the soil. Soils formed from different geological formations do not naturally produce exactly the same kinds of herbage, or, if of the same order of plants, there is a something different in their component parts—a something which gives a characteristic difference to animals of the same breed which have been reared and fed on the respective pastures, other circumstances, such as climate and exposure, being similar. In sheep stock this difference is most obvious in the wool; and in herds of cattle, such as the West Highland breed, the most marked difference is in the horn. The agriculturist may thus derive much advantage from the study of a geological map when judging of, or selecting land for any particular purpose. Here, we stand on an interesting geological position, being within a few yards of the point where these maps represent no less than three geological formations to meet, the carboniferous to the east and south, the old red sandstone to the west and north, and the spur of the Ochil range jambed into the angle between—the three meeting not far from the bridge. Again, a mile or two to the south, the spur of the Campsie Hills separates the former two, coming into the angle on the south-west in like manner; the lines of junction being covered over by a thick coating of clay, and presenting a plain level surface admirably adapted for the purpose of agriculture. The next subject proposed for consideration is botany. The agriculturist has something or other to do with plants every day, from the one end of the year to the other. Without having some slight knowledge of botany, it is difficult to distinguish a growing stem of oats from that of barley until it approaches the time when the ears are about to shoot out. I do not mean to say that the agriculturist should be so conversant with the science as to be able to give, offhand, the technical name, &c., of every plant he may meet with; but to possess some knowledge of the information the botanist has recorded, is a very useful acquirement. The botanist, after describing the structure and functions of a plant, and the order, &c., to which it belongs, proceeds to inform as to its habits and the uses to which it is, or may be, applied; as also in what latitudes, altitudes, situations, and descriptions of soil it is to be found growing naturally in the greatest perfection, and, likewise, of the effects which may be produced by culture, &c. The science also explains the method of impregnating one plant by another, and thereby producing new and useful varieties, and has contributed valuable practical information regarding the plants which impregnate each other when growing in close proximity. By paying attention to the information imparted by botany, and examining the natural products of the land, the agriculturist has the means within his power of forming a more correct

opinion of any soil and climate of which he has not had practical experience, than he possibly could do without having recourse to the indications to be obtained by this science. This is of great importance to an agricultural settler in a new country, where the vegetable products to be found growing on the land are probably the surest—possibly the only—indications of the quality of the soil and climate which at the time he may be able to obtain. This is a benefit of no mean order to the agricultural settler in a new country, as his success in life will depend greatly on the quality of the land and climate he may select for his future home; but it also applies, although in a less degree, to the removal of an agriculturist from one district to another in our own country. When the stock farmer goes to a distance to inspect a pastoral range, with the view of making arrangements for becoming the occupier, he may or he may not see the stock, or know the number thereof, which it has formerly maintained; but he has the opportunity of examining the herbage (the various grasses, heaths, and other plants), and can thereby form a very correct opinion of the quality and value of the holding. Should he there meet with plants of which he has not had any practical experience, botany is prepared to supply the want, and give all necessary information. Most of the arable land in this country has been so long under cultivation that most part of the indigenous plants are at least temporarily banished or extirpated, and have, or should have, given place to those which the occupier desires to produce; yet, even here botanical indications are not altogether valueless to the agriculturist, when he goes to inspect a piece of land of which he has not had any former experience. I daresay most of you may have found yourselves occasionally taking advantage of botany when inspecting a grass park, and, from the plants you might find growing therein, making some such remarks on the soil as, "It is wet or dry, deep or shallow, stiff or light," &c. Or, if the land was under the plough at the time of inspection, you may have found yourselves examining the hedges, if any, and probably poking about the sides of the fences, to ascertain what natural plants might be growing on the undisturbed strip of land. All of us are aware of the great benefits which agriculture has derived from this science, in the production of new and improved varieties of plants by hybridization, such as in those of the turnip and clover, &c.; and the information the science has contributed in regard to the impregnation of one plant by another has been found to be of great value in the growing of turnip and other seeds. From these, and many other circumstances which could be adduced, I am under the impression that the science of botany has been of valuable service to agriculture. The third and last subject proposed for consideration is chemistry. Chemistry truly is a magical science, and chemists are a set of clever, acute, expert fellows. They see farther into a whinstone than geologists do—they tear it to atoms, and tell of what every particle of it consists. They discourse of, measure, and weigh substances which we neither see nor feel—things not obvious to any of our senses. Seeing that chemistry has performed so much, agriculture has expected much from the science, and the inquiry now is, What has it done? Chemistry has analyzed the various descriptions of rock which geologists have discovered on the surface of the globe, and given an account of the component parts of each variety. The agriculturist thus has the means of judging correctly of the quality of a soil formed from any description of rock—of the fertilizing substances it may contain in abundance, and of what it may be deficient. Chemists also analyze the various descriptions of soils, and have been successful in detecting the presence and ascertaining the quantities of numerous ingredients; and by comparing the analysis of a fertile soil with that of a more sterile, have found out for us an approximation for a proper formula, showing the proportion of each ingredient which a good arable soil should contain. This, no doubt, is a great step in advance, but chemists have not yet been able to satisfy agriculturists that the analyses they furnish are altogether to be relied on, at least in such a degree as to be a sure test of the productive qualities of land. This may arise from the presence of a variety of vegetable matters, and substances which may have been applied to the soil as manures, or otherwise; and thus presenting a greater number of ingredients to be operated upon. Or it may be that some of the substances are in an inert or dormant state, and consequently not

liable to be so easily detected; or possibly there may be some substances present or absent, which the researches of the chemist has not hitherto discovered in any soil. However this may be, I think it is a fact that agriculturists cannot rely wholly on the chemical analyses at present obtainable, in judging of the productive quality of arable land. In respect to the products of the land, agriculture has been much benefited by the information which chemistry has supplied. It surely is of much importance to the agriculturist to have the means of ascertaining correctly what substances are carried from the land in the various kinds of crops, dairy produce, wool, and in the bodies of animals, which may be disposed of from time to time; as also what substances are returned to the land in home-made manures and droppings of animals; and even the differences in the qualities of the latter, on account of the ages of the animals, and of the kinds of food on which they have been fed. All this chemistry has done, and can do, for agriculture, and can also give a recipe for supplying the waste occasioned by the production of any particular crop or produce. This recipe may consist either of substances similar to those extracted, but in some other form; or, if the soil has been analyzed, it may consist partly of stimulants to act on ingredients present, but in a dormant condition. In pastoral districts, where little or no cultivation takes place, great numbers of animals, as well as large quantities of wool, are annually sent therefrom; and, although no return is made thereto by the hand of man, no apparent deterioration of the capabilities of the pasturage takes place; on the contrary, the numbers and qualities of the animals have rather been on the increase for many years past. Chemistry explains the cause. In these districts, the portions of the rocks which are eroded by atmospheric agencies supply mineral ingredients amply sufficient to supply the annual waste. It is not so on more level and richer soils. Even the richest of these, when constantly used for pasturage, particularly by young or dairy stock, in course of time become exhausted, and refuse to yield the accustomed pasturage. The chemist can give a recipe for the proper substances to apply to restore the pasturage to its pristine luxuriance. Chemistry explains how many practices carried out in agriculture produce certain results, such as the ploughing of the soil, the disintegration of its parts, and the application thereto of various substances; also, why it has been found to be more suitable and profitable to give animals which are arrived at maturity, when preparing them for the butcher, a different kind of food from that given to younger growing animals when preparing for the same purpose. Chemistry ascertains for agriculture the component parts of all substances which are applied as fertilizers or stimulants to the soil, so that the agriculturist can apply any particular ingredient which he is aware the land may be in want of, or withhold that which he knows it may have in excess, and can apply with some degree of certainty the proper kind and quantity of specific manure for any particular crop. Chemistry also has been of great utility to agriculture in enabling manufacturers to supply special manures made from substances which might not otherwise have been used for the purposes; likewise in detecting adulterations in substances vended as special manures; or in the variations of these from a guaranteed analysis. The same with substances used as cattle - food, smearing materials, and such like articles, which the agriculturist requires to purchase. Chemistry was of much utility when Peruvian guano was at first imported into this country, and facilitated the earlier transactions in the article by determining its comparative commercial value. I believe it was chemistry, which, some years ago suggested the application of electricity to the soil as a means of increasing its fertility, but I am not aware of any instance in which the artificial application of this subtle agent had any appreciable beneficial influence on the produce of the land to which it was applied. I have endeavoured to notice a number of the benefits which chemistry has conferred on agriculture—and they are not of small importance—and no doubt have omitted others; but upon the whole, considering the great advantages which other branches of industry have derived from this science, I think there is some cause to regret that its researches and discoveries have not effected some greater practical benefits for agriculture than it has yet done. With few exceptions this science has rather been following in the wake of agriculture, in searching out and explaining how

and why certain causes produce certain effects, rather than in the discovery of anything new. I am not aware of any one discovery made by the researches of chemistry, within the last hundred years, which has produced anything like an era in the practice of agriculture. No such era as that which was produced by the introduction of the common farm cart, or that produced by the invention of the thrashing machine, or the more recent invention of the reaping machine. It has been noticed already that the chemical analyses of soils at present obtainable are not wholly to be depended upon, particularly when these contain much vegetable matter. A considerable portion of our richest land consists of alluvial and other deposits, and these also must present greater difficulties to the chemist than soils of a more simple composition. Nevertheless I think the agriculturist has good reason to bear him out in coming to the conclusion that chemistry is behind the requirements of the day, if it cannot furnish him with a thoroughly reliable analysis of these, showing the whole of the component parts of which they consist. That chemistry has not arrived at a state of advancement sufficient to satisfy the wants of agriculture, we have a notable instance in the evidence given by eminent chemists before Parliament some three years ago, as to the sterility or fertility of the Maplin sands. Here, one would have expected there was no great difficulty to overcome, and yet the opinions expressed were so opposite as to detract greatly from the confidence which could be reposed in the correctness of the opinions of either. I am not aware that it was the professor of chemistry who first taught man to apply dung to the land for the purpose of increasing its fertility. I am not aware that chemistry taught us the benefits which the soil would derive from irrigation before the same was put into practice; or that the suggestions of the chemist were the means of causing the husbandman to apply marl, or lime, or shell-sand, or bones, or guano to the land. A substance similar to guano, namely, the dropping of sea-birds, found in the caves on our sea coasts, has long been used, and highly-prized as a manure in this country; and the droppings of the hen-house and dovecot did not require to go into the crucible of the chemist before their rich manurial properties were discovered. Chemistry has not done much towards an increased application to the land of the sewage of towns. Agriculturists have practically shown how in some instances it can be employed with great advantage in the irrigation of meadow land; but chemists hitherto have failed to discover any economical means of separating the manurial constituents from the great excess of water which prevents its profitable application to land under cultivation. The question of what is to be done with the sewage of our large towns, is engaging the attention of many eminent scientific men at the present time. It is one of vital importance to the citizen, and one in which the agriculturist is much interested. The point desiderated is the separation of the fertilising constituents from an excess of water, and the economical solution of the problem involves the acquisition, for agricultural purposes, of matter, the value of which has been calculated at many millions sterling per annum. The inducements to increase chemical research on the subject are great, and it is to be hoped that, although the problem has hitherto baffled the science, some fortunate discovery may soon be made, and the discoverer have the honour of redeeming the science from its present position of appearing to lag behind the requirements of the age—give increased revenues to the cities, and confer an important benefit on agriculture. Within the last hundred years the improvements which have taken place in agriculture have been very great. Eras therein have been noticed as having taken place. Another of these is all but effected, namely, the economical adaptation of steam power to the cultivation of the soil. This, and the utilisation of the sewage of towns to land under cultivation, appear to be the most prominent agricultural problems of the day. The mechanical arts have the merit of what has been done in the former, and the science of chemistry is confidently looked to for the solution of the latter. During the current century other branches of industry have been amazingly benefited by the researches and discoveries made by chemistry, and why this science has not conferred greater benefits than it has done on agriculture, can be accounted for only on the supposition that the requirements of the latter are more varied and complicated than those of the former, or that agriculture has advanced farther on the road to perfection.

## ROOTS AS FOOD FOR STOCK.

At the Winfrith Farmers' Club Mr. T. H. SAUNDERS, of Watercombe, read a paper on "The cultivation of roots, and their relative value as food for cattle and sheep," confessing his ignorance of any new facts bearing on the subject, which he brought forward rather with a view of gaining information from the experience of others in the discussion which should follow. They would agree with him that root growing was the foundation of all good corn farming, and upon roots and other green feed they greatly depended for the maintenance of their increased breeding flocks, as well as for the fattening of cattle and sheep which was so extensively practised in that district. The subject was rendered still more important at the present time from the fact that the turnip crop, which had become so extensively grown, was beginning to fail in some soils, just as its value was being better understood. What they desired to ascertain was how to grow the heaviest crop of roots, which should be of good sound quality at the time they were required for feed at different seasons of the year. Whilst, therefore, he related as briefly as possible what he had seen practised, and had generally adopted on his own farm, he did not ask the gentlemen present to adopt his suggestions without first weighing them in the balance with their own experience, so as to determine which was the better plan—always keeping a view that different localities required different management. Experience had taught him that the science of root cultivation and the selection of the best qualities of seed was a subject of far greater importance than he could convey to them in words on that occasion, although he felt assured it was the foundation-stone of all good farming, particularly on the light soils of that district, and the cold hilly lands around; indeed, he invariably found his corn crops succeed in rotation best after good roots. The question of the best seeds to sow depended greatly upon the purpose for which the roots were to be fed off, whether for wheat in the autumn, or for spring corn; and before he sowed turnips on his farm he always considered for what purpose they would be required. With regard to cultivation he generally sowed the greater proportion of his turnips and swedes after a previous green crop fed off the land; but to pursue this system their soil must be as free as possible from couch-grass. If they had a piece or two which were not so clean as they could wish, they should use Bentall's broadshare or some such implement as soon as possible after the corn was removed in harvest time, previous to sowing their green crop in the autumn; thus, if the land was pared during the hot weather and it was worked well afterwards, the little couch would soon be destroyed. But to do this effectually the corn should be cut close to the land, otherwise the stubble would prove troublesome in the operation of dressing. As soon as they considered the grass on the surface was dead, it should be ploughed in, and the land kept constantly stirred until it was perfectly clean; then, without further ploughing, rye, vetches, or winter barley might be sown. The first piece of wheat stubble that was ploughed and cleaned he sowed to trifolium, as soon as the corn was off, otherwise he could not ensure a plant; he also sowed some Italian rye with the corn in the previous spring, for early feed before turnips could be obtained; and for second feed he invariably sowed some hop and white Dutch seed, to feed before turnips, instead of vetches, as he thought it answered better on light or sandy soils. He would not recommend this system unless the land was perfectly clean, and they had better have no green crop than be obliged to send a man over the turnips with a prong and basket to take up all the grass which was left and growing amongst them—a process which would involve an expense of from 1s. 6d. to 3s. per acre. In the event of the land not being thoroughly cleaned, it should be well fallowed, or it would be in a foul state throughout. He was strongly of opinion that autumn cleaning was not properly attended to in many instances; and he felt sure that as much could be done in one week at that time of the year as in a month of spring. By cleaning the land early it got into a forward and better state for the root crop, particularly when the land was required for mangold, early in the spring. He could not at present enter into the detailed

process of autumn cleaning, but had said thus much in order to draw their serious attention to the important question now under their consideration, by which they would be enabled to grow a good green crop, to be fed by sheep before sowing the swedes or turnips, which would very much assist the keeping of their sheep in the early summer months, up to the middle of July, and by the extra manure produced by such green crops they might grow as good a crop of swedes or turnips as after a bare fallow, in the average of seven years. In dry seasons the crop might not be so good, but after dry weather it would be better than fallow generally. He recommended them to sow their first swedes in a bare fallow on high cold lands, where they could not by early sowing get a green crop up fit to feed in a fair season to sow trifolium, and allow their sheep to feed on the green crops in the more favourable situations on the farm. On strong clays, it was dangerous to attempt a green crop before swedes, for if the season was very dry the seed would not grow till the season had advanced, and the crop would be lost; but they might perhaps be enabled to get a crop of common turnips. The mode of sowing, in the two descriptions of land to which he had referred, must be left to the judgment of the occupier. He had a variety of soils on his farm, but had not found much difference as to which produced the best roots after a green crop, provided the season was not too dry, and the land was finely-pulverized to vegetate the seed. In the event of the season being dry, he found the free working of light, loamy soils vegetated the seed and carried on the plant best during such dry weather. He had a small portion of very strong clay land on which he never attempted to sow a green crop, if he would make sure of growing turnips. They would greatly forward the green crops and produce a much heavier yield of turnips by placing seven or eight loads of yard manure per acre—or more if they could spare it—on the land before ploughing in the autumn. Then, after the green crop was fed off, the land should be ploughed sufficiently deep to bring all this yard manure again to the top; still it should not be so deep as to lose the valuable manure left by the sheep whilst feeding the green crop, and from which the turnips or swedes would derive great benefit. By well working the land the yard manure would become thoroughly mixed up, and the young turnips would soon discover and feed on it with a benefit that would speedily become perceptible. If the land was in fallow, the yard manure should be put in before ploughing the last time but one—he preferred March or the beginning of April; then it should be ploughed-in immediately. The land should be kept constantly stirred until required to be ploughed for sowing, when most of the manure would come to the surface, when it would be mixed by the drags and harrows, and thus it would speedily come into contact with the young plants. He spoke of the different results produced from putting on the manure at the last ploughing, and stirring it up as he had described, and by the latter plan he had found a much greater weight than by the former. He was of opinion that the roots which fed upon the manure were those which had access to the air, whilst the tap roots descended into the earth and supplied the moisture. He also believed that the manure ploughed in deep was sealed down by the weight of the furrow, and in a great measure remained dormant till brought up again; but land that had only one ploughing was different, as the furrow lay as it were rather hollow and admitted the air to the roots, which would feed the plants with the manure. Having said thus much on preparing the land, he then proceeded to state in what way he liked to put in the seed. He generally drilled his swedes with about two or three cart-loads of compost, per acre, made of pig dung and earth, and a little dry ashes if he had any—sufficient just to make it run well through the drill—with two sacks of bonedust, ground finely, and about two cwt. of superphosphate, if the land had had no yard manure; but if it had, then less artificial would suffice. Some objected to the expense of drilling compost; but on his "criddy," chalky land he found it made the plant start away in early growth much the best, and a good crop was ensured. He did not like to drill the seed immediately

after ploughing, as the seed was thus put into the dry surface-earth that had been turned under, and it died away; but by keeping the land rolled down a day or two the soil became moist, and it quickly vegetated; the land should then be harrowed so as to destroy the annual weeds. They would then be able to see to hoe the turnips better and the crop would be clean. An inch was about the depth to sow in dry weather; when it was wet the shallower the better. He then stated the way in which he prepared his land to receive the swede or turnip seeds after the green crop had been fed off. He never ploughed the land more than once, and that as soon after the sheep as was convenient; it was then rolled down and dragged over, when it remained for a week or a fortnight, thus allowing the sun and atmosphere to pulverize the soil. He had often found a better crop when the seed had been sown a week or two later under that process than when sown directly after ploughing and when the land could not be properly worked. He endeavoured to get as much land ploughed and dragged as he possibly could, and then, after a middling shower, the drags and chain-harrows could be brought into use. Some people had failed in endeavouring to grow roots after a green crop; but that failure was attributable to not allowing time for the land to pulverise before being worked with the tackle to receive the seed. He thought it must have been too tough or too "criddy" for the young plant to flourish, as he had often found on his own farm when sufficient time had not been allowed, or his man had improperly worked it in his absence, that the crop was bad. He remembered having a small piece in the middle of a field so last year, while in the adjoining ridge, which had been ploughed up afterwards and sown a fortnight later, when it could be properly worked, the roots were double the size. He had scarcely ever failed by this system in all sorts of soil, and he thought by his having gained the first prize of the Club last year for the general root crop, in competition with several eminent farmers, who showed fallowed land against him, that the system was an advantageous one. That was the seventh first prize he had won in connection with the Club under the green crop system, as he scarcely ever had any fallow. He had three acres last year; but they were by no means the best, though the land had been prepared for mangold. His reason for growing roots after a green crop was to keep his sheep on it, instead of feeding off any of his regular crop of young clover; this gave him a good crop of hay to go with the turnips in the following winter, and afforded his sheep more clover heads during the summer, after being mown for hay, which was more wholesome for sheep than stale-fed land. Speaking of club-root, he thought a remedy would be found in applying chalk—or lime would do as well, only it would not be so durable in its effect. If no chalk or lime could be obtained, he recommended extra ploughing, if on fallowed land, and the seed should not be put in till the latest season. The time of sowing depended greatly on the soil and climate, and to what purpose the roots were to be applied; but this must be left to the judgment of the cultivator. His hilly cold land required to be sown a fortnight or three weeks earlier than the kindly warm soils, which, if sown too early, might look well through middle of summer; but in the latter part they became mildewed, and not above half the crop they promised to be in their early growth. Seasons would beat the best of judgments. Many of them were in too great a hurry to sow their first field, which spoiled the autumn growth of the roots when they were not required for feeding until winter or spring, when the quality was found to be bad, and they had no proof in them. As many of their farms were particularly subject to mildew, their great aim ought to be to sow the different crops at such times that they would become ripe when they wanted to feed them. As to the best sorts to grow, and their relative value as feed for cattle and sheep, he thought that was a question which would be best decided by the superior judgment of occupiers of different farms, who best knew when they would require to feed them, if for the beast in the stall, or whether it was for wheat in autumn, or for winter or spring-feeding with sheep. That was a question which he (Mr. Saunders) could not not decide, as different people were of different opinions, and the varieties of swedes and turnips were so numerous that he had not studied to grow the sorts which had been recently introduced. His practice had been generally to sow what was known as Devonshire greystone, which produced an early crop of large size, and were very proofy, though they

varied in colour. These he sowed early in June to come in for his first feed, and he took care to grow as many as he thought he should require for three weeks' or a month's supply. He sowed another piece of the same kind to come in succession, and about the same time he put in some yellow tankard or common green round, which would come for feeding in succession. About the first or second week in July he began to sow the common green round turnips for the winter after he thought it was too late to continue his swedes owing; but he preferred swedes up to that time on all the land where the green crops had been fed off, and which he wanted to stand over the winter for spring corn. He began sowing swedes in his coldest land, if the green crop was fed off, about the first week in June, and if he thought they would be required to be fed early in the winter he used Skirving's seed, as they produced the largest root; after them he sowed the Sussex, or, as some called them, Wyatt's, which, however, did not yield quite so heavy a crop, though they could make up for deficiency in size by planting them thicker. The latter sort, moreover, seldom mildewed, and would be of first-rate quality if they were to be fed before March, and did not get injured by frost. He found the old greentop to be most to be depended upon for feeding after March was in, unless the two kinds he had named had been pulled before the frost set in. Though the old greentop swede looked small in the autumn compared with the Skirving's and Wyatt's, yet they grew during the winter, and he had generally found them keep more sheep per acre after the middle of March; and they would be sound and good all through the spring if the greens were mown off as soon as they began to shoot. In order to ensure getting the different sorts all right he grew from his own seeds, selling every year those which he did not require for his own use. With respect to storing the two early kinds of swedes to which he had referred, he found those which were pulled in November and December, even in case of the winter being mild, were very superior in quality to those which had remained in the ground, when they were cut on the same field. He found the best and cheapest way was to stack them in small heaps in the same field where they grew; the heaps should be of an oval shape, about four feet wide at the base, something in the shape of a potato pit, the heaps to contain about two cart-loads each. The turnips should be all packed with the greens on, and with the crowns hanging downwards, so that the leaves might form a thatch for the heaps; and he generally put a little earth to cover just the top lines, as a ridge was bad to a rick; but this should be done as soon as the heaps were formed. By this method he found them much dryer and better than if they were merely pulled up and laid in rows all throughout the field with earth ploughed against them. If the roots were laid rather thin, it could be done well for 4s. per acre; but, if thick, 5s. was a good price. All should be pulled, and if cut from the heaps care should be taken that all the trimmings should be well spread about the field, otherwise the corn crop would be laid down where the heaps had been trimmed. He had found the roots keep much better by adopting this method than when put in large heaps and covered up; though he recommended a few large heaps where it was possible they might require to cut them in frosty weather, in which case the heaps should be earthed up, so as to keep out the frost. He attributed the decay of roots in a great measure to the freezing of the moisture in their reins, which caused them to burst. He was of opinion that no one should grow swedes oftener than once in eight years in the sandy heath soils of that locality, where the land was subject to club-root unless chalked. He thought the mangold roots were very much better adapted for such soils. They should all have a portion of mangold on their farms for feeding beasts and sheep in spring time, as it was much preferable to swedes after the middle of April; besides, they could grow one-third in weight more mangolds than swedes, with a very little extra dung, and he believed about equal value per ton. He held that mangolds were the most valuable crop they grew, though some differed from that opinion on account of their not succeeding so well with the following corn crop; but he did not complain so much of that. He grew from 20 to 30 acres annually, and should increase the quantity were it not for fear of losing his previous green crop for sheep, which he so highly valued at that season of the year; and as mangold should be sown by the first week in May, there was not sufficient time for getting a green crop before. There were three reasons

why they should grow mangold. First, because they could produce greater weight; secondly, it afforded a respite to the land from swedes until the next rotation of the farm, and would prosper where swedes would get diseased in many soils; thirdly, it was not liable to half as many enemies as the turnip, and should the seed in any way fail, the land would be in first-rate order to try for swedes. If necessary, mangold could be kept for feeding all through the summer months. With regard to preparing the land for it, he invariably followed the same method as for turnips on a bare fallow. If he intended putting his mangolds on the ridge system, he generally ploughed in about six loads of yard dung per acre early in the winter, and about as much more put under the ridge just before sowing the seed. When the ridges were open he sometimes sowed 2 cwt. of Peruvian guano; but if not, he sowed the guano when the plant was horse-hoed a second time, hoeing sufficiently deep to stir it well in. But when he sowed his mangold on the flat he only put the first quantity of manure which he had named, and then he usually drilled 2 cwt. of superphosphate and  $\frac{1}{2}$  cwt. of bones, drilled with about three cart-loads of compost just as he did for turnips, then he sowed the guano broadcast and hoed in. He usually ridged 27 in. apart, because that was a convenient width for the dung-cart wheels, but 24 in. was sufficient on the flat. He thought the ridge system was cheapest and best when the farmer had plenty of yard manure to spare. He preferred, if possible, to ridge up his land two or three weeks prior to sowing the seed, as the small weeds could be destroyed by means of a light seed harrow. This should be done two or three times, and if the land was very weedy they should run a double-mould plough very shallow, which by turning the earth again would destroy the small weeds in the hollow of the ridged land. He then put in his drill and drilled about 6 lb. or 7 lb. of seed per acre to ensure a thick plant, at about three-quarters of an inch deep, and this he followed by a light seed harrow. He did not recommend rolling, as the land was apt to crust after a hard rain, and in such cases he had found the seed not come up well; but if dry he put the seed full an inch deep, or rather more. There was one other reason why he liked the ridge system, viz., that they could use the horse-hoe early, if their land was ready, as they would know where the drills were. They could not use the horse-hoe too early in the season, after the drills could be distinguished, for they would kill more seeds by once hoeing them in their infancy than twice afterwards. If they were troubled with chickweed, it could not easily be destroyed after it had become old. They could not be too liberal with hoeing, and the crop ought to be horse-hoed twice before they were singled by hand, as they could see how to go close to the plant a second time. He was not an advocate for singling the plants to their proper distance until they were sufficiently strong to stand against the hoe; and, as soon as they grew upright, the horse-hoe should be again used, which would kill the weeds that had been pulled between the drills by the hand hoe. The hoeing to which he had alluded referred equally to swedes and turnips as well as mangold. With regard to the distance between each plant, he related an experiment which his son tried some years ago. He took the trouble to plant several drills on the ridge, at 27 in. between the rows, all through the field, from 8 in. to 16 in.; and, upon weighing the lots when taken up, he found the 10-in. drill to be the heaviest, and the 9-in. next. He was in the habit of drilling all his swedes and turnips at 18 in. apart; and as he grew nearly all after a green crop, and found a thick plant was the most weight, he generally endeavoured to get those left from 7 in. to 9 in. between the plants. In conclusion, he invited discussion upon the subject.

Mr. W. BUDDEN thought it was not the best plan to burn the couch; but he would rather raft it soon after harvest; and, by working it about, a greater portion of it could be killed; and it should then be ploughed in as deep as possible. By that system they would get rid of the couch before they wanted to sow the turnips; and from the crop he sowed last year, he did not take a single cart-load of couch. He did not agree with drilling compost, as the trouble of mixing it was so great.

Mr. C. BESANT spoke in similar terms with respect to the couch: he preferred to treat it as Mr. Budden had said than to burn it. Referring to club-root, he sowed a piece of swedes for early feeding, after trifolium, and the plants grew well until after they had been hoed some time, when he found

they had become club-rooted. He could not account for this in any way.

Mr. W. LONGMAN expressed his opinion that the manure should be sown broadcast over the land, rather than be drilled in, as the plants derived greater benefit from it. If a portion was sown broadcast, and the remainder drilled, it would be equally distributed over the land.

Mr. READER observed that frequently, when superphosphate was drilled with turnip-seed, the plants grew away rapidly at first; but, as they attained size prematurely, they became rotten early in the season. If they wanted a good crop of turnips, they ought to have the manure stirred in all over the land. He sowed bones broadcast early in the season, though he should not do so in light lands, because there was not acidity enough in it to dissolve the manure, as was the case in most of their sour lands. Mr. Saunders had justly observed that every person must sow their land according to the soil. He (Mr. Reader) believed Mr. Saunders was perfectly justified in growing a green crop previous to a root-crop; but if he was to try that experiment, he should lose half his crop. He knew a gentleman in that room, who tried it most unsuccessfully some years ago, and had not adopted it since. If they had kindly soil, and well situated, he thought they might grow a previous green crop with advantage; and in many parts of Hampshire they can grow better root-crops by adopting this system than after fallow. He was somewhat surprised to hear Mr. Saunders advocate mangold as the best root-crop; and he maintained it ought not to be included in the general root-crop. He agreed that it was an advantage to grow mangold, as the crop produced was of such great weight.

Mr. SCURT said this was a most important subject, as a good root-crop was the foundation of all good farming. It required a great deal of judgment to grow roots after a previous green crop. Speaking of rafting after a green crop, he said he liked the plan, if they had strength enough to carry it out well. By rafting behind the sheep, they not only had a chance of securing a better plant, but the manure left by the sheep was mixed with the soil, instead of its being washed away by the rain. With respect to chalking as a preventive to club-root, he advised them not to chalk too heavily, as they might destroy the stability of the soil. If there was any acidity in the soil, by putting mangold into it, instead of swedes, that acidity would be extracted, and the swede-crop would probably be a good one in the next rotation. There were many sorts of swedes; but he thought more depended upon the time of putting in the seeds than the variety chosen. He did not agree with Mr. Saunders growing his own seeds.

The CHAIRMAN proposed a vote of thanks to Mr. Saunders for his admirable practical paper; and, Mr. Saunders having made a short reply, the proceedings terminated.

**SAWING OFF THE HORNS OF CATTLE.**—Professor Spooner, President of the Veterinary College, London, on a trial in Dublin gave the following evidence: "I have said that I consider this to be a very gross act of cruelty, and for this reason, that the horns of oxen are unlike those of the deer species. They have a large proportion of bone growing out from the bone of the head, and that is surrounded by a heavy sensitive structure, so that, to cut the horns, they had to go below where it was simply horny, and the animal had to suffer great pain. The nearer the operation was performed to the skull the greater the suffering. That bone was hollow—that is to say, it had not one single horned cavity—but it had several cells which extended into the head, though not to the brain, but close to it. These cavities were exposed, by the removal of the horns, to the air; and as they were lined with a delicate sensitive membrane—there being besides a delicate sensitive covering outside—great suffering must be caused. The cavities were never intended by nature to be exposed to the air, which brought on an inflammatory condition. These cavities were very apt to be inflamed, and the inflammation was very likely to be extended to the membranes of the brain, causing madness, lockjaw, or other dangerous results. This operation is one of the most painful and unwarrantable that could possibly be performed on cattle."

## AUTUMN NOTES.

The life of a farmer is popularly supposed to be one of uninterrupted pleasure, enjoying as he does all the blessings which abundant exercise and the purest of air can confer upon him. By many he is supposed to spend his time in the pleasing contemplation of Nature's beauties, as exhibited in graceful contrast during the recurrence of sunshine and shower and the ever-varying seasons.

As the natural consequence of a feeling which has such a firm hold on the popular mind, every succeeding year finds numbers of people embarking in the business of farming, who, having made some money in trade, imagine that they have only to get the lease of a farm, remove themselves and families and household goods to the country, and forthwith begin a life of ease, comfort, and enjoyment.

To such persons the amount of pleasurable excitement and happiness which they derive from their country life is generally more regulated by the amount of capital otherwise invested should they be fortunate enough to have such a reserve, than by that portion of their fortune which they have devoted to farming.

In reality farming is a business beset with anxiety, and so much of the year's success depending on the timely and thorough performance of each operation, his personal energies are so much taxed and his time so fully occupied as to leave but little time for relaxation.

Nearly every season is alike to him, as one round of operations are no sooner completed than another equally important claims his attention; nay, so harassingly quick do the affairs requiring almost instant and urgent attention succeed each other, that he finds it sometimes difficult to decide whether it were better to begin making preparations for next season's crop before having finished securing that of the present.

This is often the case when the harvest has been a late or protracted one, when on certain soils the seeding of the land with wheat must be proceeded with at all hazards, to delay being to risk losing probably the only opportunity that may be afforded for the entire season of getting this most valuable of all the cereals committed to the earth.

During the earlier part of the season he is equally engaged, when Nature in the clear blue sky overhead, the green earth underneath, the warm soft atmosphere, and trees and plants in brilliant dress, shows to the most unobservant that summer, the pleasant season of out-door enjoyment, has arrived. Every one is then bent on pleasure. The citizen hurries with his family to the country or the coast, there to recruit his own and their exhausted energies, and bring back a shade of colour to the pale cheek.

The man of business, who, albeit, devoting himself for the greater part of the year to his office or desk, is yet a passionate lover of the gentle art, and a life-long admirer and follower of Old Izaak, now hastens with railway speed to his favourite river, perhaps several hundred miles distant from the scene of his ordinary labours, there, with rod, line, and fly, to enjoy his brief holiday in his own peculiar way.

Solitary it is to be sure, and often singularly barren of creature comforts, the rough very frequently predominating over the smooth; but the pleasurable excitement which is the invariable result of even a moderate degree of success, is not to be bartered for any amount of that yellow dust which ordinary home-staying mortals call "gold."

While others are enjoying themselves in this and other ways, the farmer is busy in the field, straining every nerve to get the green crops in in good season; and long before he has this part of the year's business completed, the hay has become fit to cut, and demands his instant attention.

When this occurs—and it very frequently does—he has two important processes on hand together, neither of which will brook delay, every day that passes shortening the season, and lessening the chance of a full crop on the one hand, and on the other a day or two's neglect may injure the quality of the hay very materially, and, in the event of a break in the weather, greatly increase the labour of saving it.

We thus find that the farmer, living on the profit of the

land he cultivates, has but little time for that kind of pleasure which consists in absence from the scene of one's daily pursuits, and exclusive devotion to some species of amusement for a space of time, however brief; yet, if a contemplative turn of mind, he can extract a certain amount of pleasure from the scenes by which he is at this time surrounded.

Vegetation now makes rapid strides, each day almost making a perceptible difference in the growth of the various crops; the fields are clothed with verdure, and the year's food of man, and the animals he has taken under his care, rapidly approaches maturity.

There is quiet enjoyment to be derived from the contemplation of the crops as they bask and glitter in the sun, or bend gracefully in miniature waves as the wind sweeps across the fields. Hope rises high in the bosom of the farmer as he sees the crops with which he has taken so much trouble, and gone to such expense, covering the ground, and tillering out under the combined influence of heat and moisture. The broad curling leaf, the delightfully rich colour, and the strong stem gladden the heart of the cultivator, giving him promise of a remunerative return for all the labour and anxiety undergone by him in the preparation of the soil and getting in the seed. There is a charm in looking at a healthy and promising field of corn, which we think can only be properly appreciated by those who have been behind the scenes, and have borne a share in the heat and burden of the day, by taking an active part in the labours connected with it, or who, although not exactly having put their hand to the plough, have been present at all the preparatory operations, and have a pecuniary, and therefore vital, interest in the success of the crop.

However well things may look during the earlier stages of growth, and whatever the amount of laudable pride evoked in the bosom of the tiller of the soil, when regarding the flattering appearance of his crops, it unfortunately does not always fall to his lot to realize in harvest the rich reward he anticipated.

Last year late frosts injured the wheat crop to such an extent as to reduce the yield in many cases to half, and scarcely a district in Great Britain or Ireland escaped without a loss of at least one-third of what might fairly have been estimated, from the appearance of the crop when growing.

The present year has been an anxious one, and very many farmers will suffer heavily on account of the long-continued drought, particularly on light land. Not to speak of the temporary annoyance and inconvenience occasioned by the scarcity of water for live stock and household purposes, the crops have suffered severely. By the reports published in the *Mark Lane Express*, we find that turnips in many districts are either almost or altogether a failure; hay not half a crop; and corn, which has arrived at maturity more by a drying off than by a really ripening process, can scarcely be expected to turn out such a quantity of clean corn as will amount to anything like an average crop.

Such casualties are unavoidable, and human foresight is powerless to prevent them. It is utterly impossible for the most experienced and skilful in agricultural matters to foretell or even give a close guess at the probable yield or outcome until the season is well advanced; in fact, scarcely until a portion at least of the crop has been subjected to the final and truthful test of the thrashing-floor. The man whose heart is in his business, and who not only follows it as a means of living, but loves it for its own sake, does not become discouraged by even a succession of difficulties; but, "by no failure vexed," makes more strenuous efforts to overcome the natural difficulties by which he is surrounded. He brings in all the aids which science and practical experience has placed within his reach, tries new experiments for the purpose of lessening the cost of production and for hastening the growth of the various crops, and feels always certain to succeed the next.

There is one particularly favourable feature in the character of the present season which recommends itself very strongly to the notice of the agriculturist who is on the watch for every

opportunity afforded him for promoting his interests. This consists in the unusual earliness of the harvest, which permitting the fields to be cleared of the grain crop in time for rape, mustard, turnips, and grass-seeds to be sown on the stubbles, with a reasonable prospect of a considerable increase in the available amount of food for sheep and other stock for the spring, thus to some extent enables him to redeem a portion of the loss sustained by the partial or total failure of the summer-sown crops. Referring to the same authority to which we have already alluded, the *Mark Lane Express*, we find that this opportunity is being made largely available, the example being set by England's leading tenant farmer, a gentleman whose advice and example may at all times be trustfully followed. Notwithstanding the apparent lateness of the season, it is astonishing how Nature compensates for this drawback, by a quickness of growth and a rapid approach to maturity quite unknown at an earlier period. This is accomplished by the high temperature to which the soil has been raised, acting like a hot-bed upon all seeds submitted to its influence; the plants are up at once, and pass through the earlier stages of their growth with astonishing rapidity, and actually, when well nourished, get forward in time to have all the benefits of the maturing months—viz., end of August, September, and October, and even November some years, without having the disadvantage of having languished under a burning sun for months previous, and become hard and cranky in consequence.

It is considered rather discouraging to be sowing late crops, more, we think, however, from the thought of its being unusual and out of season than from any well-founded fear of their not doing well, as when given a fair trial they far oftener succeed than fail. No later than last season we sowed seven acres of yellow and white turnips after winter tares, at a time when the soil was in dust, containing apparently not a particle of moisture; yet trusting, as we have this year done again on a more extended scale, even at a later period, that the quick rush they would make when rain did fall would enable them to overtake those sown nearly two months before. They lingered long, and although thinned in August, made no bulbs until well on in September; but when the bulb-forming process did begin, they seemed to attain their full size almost in a few weeks. When lifted in December they were a magnificent crop, the size being large—no blanks in the drills: (by the way, a most important feature, without which a full crop is scarcely obtainable), and scarcely a rotten turnip to be found in the entire break.

It is highly important that notes should be kept of former experiments, either of one's own or one's neighbours, which may have come under his observation; as former successes are a great encouragement to attempt certain deviations from ordinary routine, exceedingly necessary under existing circumstances, but which might hardly be attempted but for the fact of former experience being noted down, acted upon, and so rendered useful.

J. S.

## FARM LEASES IN SCOTLAND.

At the quarterly meeting of the Ayrshire Farmers' Club, Mr. DAVID CUNNINGHAME, of Chapelton, the President of the Club, read the following paper:

The subject of leases between landlord and tenant has lately received a good deal more consideration than at any former period; still, there are many points of great interest, that affect both the contracting parties, that have not been considered with that due forbearance which their importance demands, by those whose duty it was to do so. Many landlords labour under the impression that it is only by inserting very stringent clauses in the leases they grant to their tenants, that they can protect themselves from operations on the part of their tenants that will deteriorate the value of their land. But the exercise of a sound discretion on their part, in the selection of tenants only who are possessed of the necessary capital and skill, is the best of all guarantees they can obtain that their land will be both improved and more profitably cultivated by acting in this matter, as here pointed out, than by any clauses in a lease, however protective they may appear on paper. One of the most valid objections to fettering clauses in leases is where a landlord and tenant agree and enter upon an improving lease on a farm standing in great need of improvement. In such cases very often neither the landlord nor tenant may have formed a correct estimate of what various portions of the land is calculated for, and consequently to hamper, by inserting clauses binding them to a certain course of culture, might be highly prejudicial to both their interests. In such cases the best plan is to act in a conciliatory spirit, and if the landlord has been careful to select a proper tenant, his skill and capital is ample security that whilst he is doing the best he can for his own interest, he is also acting on the best course for his landlord. There are landlords—and they are not a very small minority—who think that they are prevented from getting the full value of their land when they are restricted in their choice. To men possessed of both the necessary capital and skill, opinions on this subject are various; but there is so much competition among farmers, both with and without the requisite means and knowledge, that it is an acknowledged fact that land in the West of Scotland generally is let for all it is worth, and in numerous instances for more. The greatest obstacle that stands in the way of a landlord obtaining the very highest value that can be got as rent for his farm, is the unjust, antiquated, and absurd law of hypothec. Many a well-qualified, industrious man, but who has not quite the full amount of means necessary to enter upon

a system of culture which he thinks the only one that would be profitable, is prevented from offering, and simply so from the greater difficulty that he has to obtain the necessary advances from those who would be willing to do so if this remnant of feudalism were wiped out of the statute book. Nothing can be more prejudicial, not only to landlord and tenant, but to the general public, who have a clear interest in its abolition; for whatever obstructs the introduction of skill and capital into our agricultural pursuits is a national loss. In many cases now the means invested by the tenant are so much in excess of what in former times was the case that it not unfrequently happens where an active and well-qualified tenant enters upon an improving lease, the capital requisite for the successful development of such a farm is at least a third of its value. Another great error very general among landlords is the stock of game maintained on their estates. The majority of farmers do not object to a fair but limited head of game, so as to afford a fair day's sport in the sense in which the word "sport" ought to be interpreted by the true and genuine sportsman. But a little reflection ought to convince all reasonable men that a tenant who has to feed and maintain in excess either rabbits, hares, or winged game, cannot but suffer a sad waste of all that his industry has placed there—not certainly for the purpose of maintaining a stock in which there is in reality no property until they are in the sportsman's bag, but for the better and more reasonable purpose of rewarding him for his skill and industry; and this injustice preases in a far more injurious proportion on the tenant who has pursued a system of culture known as high farming, than on the careless and indifferent tenant who takes matters in the old-fashioned manner of his grandsire. The previous part of this paper has been mainly devoted to the duties of landlords. But tenants have duties to perform, and it is as important they should be well understood and acted upon by them as it is in the case of the landlords. They should carefully examine and consider all the clauses in any lease presented for their acceptance. In many instances there are clauses inserted totally at variance with the common laws of the land, and that could not be maintained in a court of justice; in others, where from insufficient knowledge on the part of either landlord or tenant, or, as often happens, of both the parties, covenants are inserted totally destructive of both interests. Mr. Baird, of Cambusdoon, in his capacity of Chairman of the Ayrshire Association, at one of the society's dinners lately, after enumerating many good objects the society had been the

means of disseminating, mentioned that there were still numerous reforms to be pointed out and overcome; and in illustration of the subject now under consideration, stated that he had lately seen a man struggling with his horses and men to employ land for a purpose for which it was totally unfit, for the mere purpose of carrying out some preposterous clause in a lease foolishly entered into. An extensive proprietor in this county has lately introduced, in a partial manner, the system of yearly tenancy, or as it is commonly known in England by the term "tenants at will." No satisfactory investment of either skill or capital can be made in land so held. What has made the agriculture of Scotland what it is but the almost universal custom of nineteen year leases? and we can conceive nothing that would prevent the advancement of successful agriculture so much as this Anglicised system, which, if allowed to take root here, will prove itself of a retrogressive character, and highly disastrous in its effects. The mode in which the attempt to introduce it here has been made is worthy of remark, as it is of a most insidious nature—viz., to allow tenants whose leases have expired to continue as yearly tenants. We trust that the independent tenantry of this country will set their faces against any such retrograde movement as this, no matter by whom it may be attempted to be introduced. In its very nature it is a blow at investment in land by tenants, and also an insidious mode of undermining their independent action, and ought to be resisted as a most dangerous innovation. These are a few of the ideas that we think deserve consideration, but there are no doubt many others that some of my brethren better qualified will in due time bring under your notice.

Mr. WALLACE (Kirklandholm) said some very important points had been brought forward in the Chairman's paper. One of these was the law of hypothec. He believed that mistaken notions in regard to this law existed on the part of both proprietors and tenants. Many on both sides thought it was working for their benefit, whereas it was in reality working to their injury. He had known cases where the tenant thought he was being benefited by his landlord's leniency in allowing him to go on, when it would in reality have been better for him to have left the farm he was in when he had something left to go on with in a place he was better fitted for. The proprietor might think he was doing the tenant a favour, when in reality he was injuring both himself and the tenant. He had a great objection to the system of leaving the bargain for a new lease to the last year of the tack, as he believed it to be a great barrier to improvement. The bargain should take place at least two years before the expiry of the lease. They should endeavour to look at this general subject that had been brought before them, from a landlord's point of view as well as from their own, if they were to expect any advantage from the discussion.

Mr. MURDOCH (Holehouse) said no one who had ever seen a farm lease could have failed to observe that the tenant was bound by every conceivable and inconceivable manner to perform an immense number of certain and uncertain things, and bound, too, with a legal depth and profundity that he perhaps failed entirely to appreciate; while, on the other hand, the clauses binding on the landlord were neither numerous nor stringent. That some sort of written agreement ought to exist, no one doubted, though he had known farms held without any regular lease at all, or even any prescribed rotation of cropping laid down. Notwithstanding this, everything went on smoothly between landlord and tenant during the whole currency of the lease, and the farms, so far from being spoiled, were about the best farmed in the district, though no uniform system of cropping was maintained throughout. Stringent leases might be thought necessary to ensure good management, but there never was a greater mistake. They would no more make a man a good farmer than would Acts of Parliament make a man honest, sober, prudent, or industrious. He would look well to get a man of practical experience and capital, and give him, so to speak, some scope and freedom to adopt any better system he could devise, or that might turn up in this ever-progressing age, or to change his system should circumstances make that necessary—due regard being had at all times not to deteriorate the condition of the farm. A good horse might be rendered comparatively useless by being too much curbed, from a groundless fear that if he was allowed head-room he would run away and throw his precious rider. Let not landlords seem so suspicious of the tenant being a

good man only so far as he was forced; let them trust his honour a little, for he had to trust his landlord's a good deal. Surely to bind a tenant to become his landlord's gamekeeper was as dishonourable to the landlord as it was degrading to the tenant. Let them give a man a chance to develop his skill and energy in following out his profession successfully to the best advantage. Let there be no tight-lacing or Chinese shoe-pinching, which, though done from no bad motive, tended only to deform and cripple natural beauty and usefulness. Since the abolition of the corn-laws, the farmers of this country had had to compete even in the home market against all kinds of foreign agricultural produce. Let them hope the time was not far distant when all restrictive and unnecessary laws, such as the hypothec and game-laws, and also over-binding leases, would be swept away also. All they asked was fair play, and no favour. They were not afraid to face any competition, only they could not do so bound hand and foot.

Mr. STEVENSON (Silverwood) thought farm leases should not be drawn so as to restrict a tenant too much. He should be at liberty to do with his farm, in the way of rotation of crops, as he saw would pay him best—due regard being had to keep the farm up to the proper mark. Some years one crop might do better than others; in other years, again, what might have done well before might do very badly. If a farmer was restricted to a particular crop, he very often was a loser, whereas he might have been a gainer had he been at liberty to alter his mode. Something had been said about some landlord in this district doing away with leases altogether. There was one landlord, he understood, who was not granting leases at the present time, but was just allowing his tenants to go on on their old leases; and as these leases were not at all bad leases, it would not be very much against the tenants. Still he agreed that it was a bad thing to be without a lease, as it did away with the independence of the tenant very much. He could not speak personally as to the game clauses in leases, as there was no game in the district where his farm was situated; but it was no doubt a very bad thing for a tenant to hold a lease under which his crops might be all eaten up by game and rabbits. One could have no idea of the loss sustained in this way.

Mr. WHYTE (East Raws) said this seemed to him to be a more fruitful subject than he had anticipated. A lease was a contract between a proprietor and tenant, and he thought it ought always to be as brief and simple a document as possible, so that each could thoroughly understand how it bore upon him. With regard to fixing a rotation of cropping, he thought in the most of cases that was quite unnecessary. If a proprietor was satisfied as to the skill and ability of the tenant, he ought to grant him a considerable length of lease; and as leases in Scotland generally extended to 19 or 20 years, he thought it would be quite sufficient with a trustworthy tenant to lay down rules for the last four years of the lease. And after the first sixteen years, the tenant ought to have such a knowledge of the farm, and the proprietor ought to have such a knowledge of the tenant, as that both could come to an understanding to enable them to make arrangements for another lease. He thought it was always a desirable thing for both parties that a second arrangement should be made before the first one was completed; it enabled the farmer to manage better, and must keep the proprietor's mind more at rest. With regard to the game laws, it was generally well understood by the tenant on entering upon a lease that it was the law of the country that game had to be preserved. But for a tenant to sign his name to a paper obliging him to maintain an indefinite amount of game, was what he ought not to do. In some cases, he understood, the lease bound the tenant to protect game to an ordinary amount, and provided that, if it increased, he should be entitled to damages, to be settled in case of dispute by arbitration. But he understood it was a difficult thing to get any damages off a landlord. It should be the tenant's look-out to see that he did not bind himself to maintain an indefinite amount of game.

Mr. STEVENSON (Hillhouse) said he had much pleasure in bearing testimony to the practical and valuable paper which had been read by the Chairman. It was well worthy of the careful consideration of all interested in the welfare and prosperity of agriculture, and if its principles were carried out upon the various estates and properties in this county, it would tend to foster and cement that good will and affection so essentially necessary between proprietor and tenant; for in reality

they had but one common interest. It was therefore the interest of the former to give such encouragement to farming as would induce the latter to carry out the necessary improvements, so that in the end both would be benefited. One could not but admire the latitude and liberality which were given by some proprietors and agents in this county to their tenants for the cultivation and improvement of the land. He considered that much of the hardships and difficulties that tenants had to contend with was the result of a too keen competition for farms. When a farm was to let, a great number of candidates presented themselves, and as some had extravagant ideas regarding the productiveness of the land and the profitability of farming, they offered rents which were quite extravagant, and submitted to leases which were quite unsuited to the nature and requirements of the farm; and afterwards, when they obtained possession, they had to submit more to the good-will and generosity of the proprietor than to their own common-sense and prudence. If more care and moderation were bestowed in this matter, there would be less reason to complain of high-rented lands and restrictive leases afterwards. He believed that the system of granting leases to the highest bidder had, more than any other cause, contributed to retard the progress of agriculture in this country, for, wherever land was extravagantly rented, it soon depreciated in condition. The tenant, finding that his capital was being unprofitably expended, and becoming embarrassed in his circumstances, the land thus became exposed to all the consequences of an impolitic and beggarly management. But more enlightened views were beginning to appear and to be acted upon with most judicious effect upon many properties around. There could be no doubt that agriculture in Scotland had prospered under the leasehold principle. Men acquainted with the practice of husbandry knew that the chief profit derived from farming was obtained by a progressive improvement of the land during its various crops and rotations—all of which required a series of years to bring round a fair return for the capital and labour employed. A man in possession of a lease engaged in the effective improvement of his farm, because he had the moral certainty of reaping its benefits during its continuance, and it was therefore a stimulus to spirited improvement. But he could not concur in all that had been stated in regard to yearly tenants, spoken of as adopted on a certain estate in this county. Under some proprietors the tendency might be as described, but upon the estate alluded to it had rather been conducive to the interest and benefit of the tenants, as no rise of rents was demanded, as generally occurred at the renewal of a lease, and they had the same advantages and encouragement given to exercise their judgment and skill in the cultivation of the farm as those who were possessed of leases upon the estate referred to. In England yearly tenancy was the rule, and leases the exception; and, judging from the manner in which it worked there, no danger was to be apprehended, as it seemed to be beneficial to the tenant, both for permanency of occupation and moderation of rent. The rents were considerably cheaper, and tenants much easier in their circumstances, and were as much free agents as the farmers in this county. If the alternative of their present condition and that of a lease were presented to them, the majority of the farmers in England would not desire to change. In granting leases, no one who had studied the subject would deny that restrictions were necessary for the security of the proprietor; but they should be made appropriate to the soil, and as few and simple as possible. While the tenant should be prevented from doing mischief, he should not be fettered so as to bar improvement; for all undue restrictions cramped the enterprising and intelligent farmer, and impeded the progress of agriculture within our land. A most beneficial result would take place if leases were drawn out with judgment and due consideration to the nature of the soil and the requirements of the farm. This demanded no ordinary degree of knowledge, and could only be accomplished by men who were conversant with the details as well as the principles of husbandry. Such leases as were drawn out by legal advisers were often harassing to tenants, because they were inapplicable to the character of the particular farm. Inattention to this proved injurious to many a farm, and brought disappointment and loss of capital to many a good tenant. To a farmer who was known to practise the approved modes of modern husbandry, the management of the land might be entrusted with safety during the greater part of the currency of his lease, for his own interest would teach him

not to misuse it during that period, and it was only towards the close that restrictions were necessary, and when injury might be apprehended. The man who did so diminished his own profits and injured that of the proprietor; therefore leases should be renewed some time previous to their expiry. Were such a conciliatory plan always pursued, and confided to men of marked knowledge, it was inconceivable how much estates might be improved both to owner, the occupier, and the public.

Mr. YOUNG (Kilhenzie) said his experience of farming had been very short, and he probably would not have ventured to speak at all, had it not been for a few remarks of the last speaker. He totally disagreed with that gentleman on the subject of yearly tenancy. He had a strong opinion that the present efficiency of agriculture in Scotland was greatly due to long leases; and he thought the tenantry of Scotland were much indebted to the proprietors for giving them long leases. Nothing could be more calculated to strike at the independence of the tenantry, or to prevent farming being carried on in an efficient manner, than the system of yearly leases. He as a tenant would think twice before he laid out £1,000 or £1,500 on a farm if he had no lease. He might think the word of his landlord good enough so long as he lived; but life was uncertain, and that was sufficient reason why no prudent man would lay out money on the improvement of his farm without a lease. But he thought there were clauses in most leases which would be more honoured in the breach than the observance. To ensure a good understanding between landlord and tenant, it was necessary that leases should be put upon an equitable footing; but many of the clauses in leases at present were not fair, just, or reasonable. For instance, he held that a landlord was as much entitled to take the highest price he could get for his land as they were to take the highest price they could get for their produce; but after taking the highest price for his land, he could scarcely see the fairness of his reserving the right to consume all that grew upon the farm by game and rabbits. They were living in days of change, and he hoped the day was not distant when there would be no such thing as a lease in Scotland requiring a tenant to preserve rabbits. To ask a man to judge as to the increase of game or rabbits was to ask him to do an impossibility. Rabbits were extremely prolific, and he was persuaded that it would be for the benefit of the public, of the tenant, and of the landlord if there were no such clauses as those requiring the preservation of rabbits. As to the law of hypothec, he considered it was a very bad law, and that the sooner it was swept away the better; but the practical grievance from game and rabbits was, in his opinion, greater than from the law of hypothec. Still it was bad enough. There was a clause in many leases prohibiting the tenant from selling straw off the farm. Last year many of them could have sold straw at 1s. a stone, whereas by turning it into farm yard manure it was not worth more to them than 1d. or 1½d. a stone. Clauses like this he held to be detrimental to the interests both of landlords and tenants. There was another matter, which perhaps was scarcely within the scope of the discussion, but to which he might be allowed to refer. It was embodied in the lease, but it was the custom over the most of Ayrshire, that when a man took a farm, arbitrators were appointed to fix as between the outgoing and ingoing tenant the value of repairs needed on offices, &c. Now a case came under his notice recently, in which two gentlemen of great experience and considerable intelligence were appointed arbitrators, and in the exercise of their discretion they allowed 30s. for the repairs needed on some office houses; but when the tenant came to put them in repair, it cost him £20 to do it. The sooner that system was altered the better. The arbitrators ought to decide between the ingoing tenant and his landlord, and not between the ingoing and outgoing tenants.

Mr. THOS. M'CREATH (grain merchant) agreed with Mr. Young and other speakers in regard to the advantages of long leases, and the evils that would arise from the adoption of the system of tenants-at-will. He thought as a rule that leases were too one-sided; that they were drawn up to protect the landlord at the expense of unnecessarily hampering the tenant. There were clauses in some leases that he was sure landlords would be ashamed of if they were brought before the public. For instance, there were restrictions as to the keeping of guns and of dogs, which were not in keeping with the spirit of the

times. With regard to the game question, he believed on some of the largest estates in this county there were clauses in the lease that enabled the proprietor to stock the farm with any quantity of game he might think fit, without the tenant being entitled to one penny of compensation. He maintained that it was unjust and unfair to ask a tenant to sign a document of that kind. He knew it was often said that game would be kept in moderation notwithstanding these clauses, and that no hardship would come to the tenant; but he knew of cases where there had been hardships. Only a few years ago a gentleman with whom he was acquainted re-took his farm at a considerable advance in rent. There was a considerable quantity of rabbits on the farm, and he was told he would be allowed to kill them, but that it was a rule of the estate that the clauses regarding game must be put in the lease. He took the farm on that footing, and in a year or two was told that they had changed their mind, and that the proprietor would undertake to kill the rabbits that the tenant fed. The proprietor accordingly pocketed the value of them, amounting to about £70 or £80 yearly; and the tenant, who as an agriculturist was second to none in the county, felt it to be such a hardship that he gave up his farm. There should be no clauses in leases that could not be carried out in practice. A tenant should not live upon sufferance, but should be in a position to carry on his farm without unnecessary interference on the part of his landlord. In regard to cropping, it was a very absurd thing in a country where systems of agriculture were changing so much as had been the case here for the last number of years, that the tenant should be tied down to a fixed rotation of cropping for nineteen years. This was making the proprietor the manager of the farm, and not the tenant. The tenant should have the management of his farm in his own hand, and the better he managed for himself, the better would it be for the proprietor. He agreed with Mr. Whyte that the clauses in leases should be very brief. He admitted that a proprietor was entitled to protection, but if his farm was managed according to the rules of good husbandry, he did not think he would find much damage done to his land at the end of the lease. Stipulations might be made as to the last four years or so of the lease, but for the first fifteen years the tenant should be left to the freedom of his own will. Restrictions would not make a bad farmer a good tenant; but had made many a good tenant a bad farmer, by obliging him to practise a rotation of cropping not suitable for the land he was working. He was much gratified by the sentiments expressed by Mr. Baird of Cambusdoon at the last dinner of the Ayrshire Agricultural Association. These sentiments, if adopted generally by landlords, would tend much to the success of agriculture in this country. They contrasted very markedly with the ideas expressed not very long since by a proprietor at a meeting of the same Association, who objected to the introduction of portable steam mills, on the ground that the tenant might thrash off all his crop, and run away and not pay his rent. Proprietors were getting now to have more confidence in their tenantry, and the more they did so, the more would they be respected, and the better would agriculture flourish.

Mr. BROWN (Ardneil) might say that neither restrictive leases nor the game laws had ever done him much harm; but he was perfectly satisfied of the evils that would arise from a tenant being tied up to an undue extent. His opinion was that a farmer who had done his best for himself for twelve or fifteen years, was doing his best for the proprietor and for the community at large. He did not think it was right that a man should be tied down by restrictions to any system of farming, as the party making them might not know whether it applied to the farm or not. The tenant ought to know in the course of his practice what system was best suited for his soil: he ought to know what was the best crop to put upon his land, and if one failed he ought to be at liberty to try another. As regarded the no-lease system, he would disapprove of it. It might be that in England the tenants under that system were very well off, and he supposed in Scotland they were very well off too. He believed they might be as kindly treated as the others. It might be that those who had had good leases were continued on the same favourable terms; while those who had had hard bargains would have them still. But, undoubtedly, it took away a tenant's independence. It would not be right to invest £1,600 or £2,000 in a farm without a lease. He did not speak of improvements at all; but it would

not be right for a man to invest money to any amount in his farm when he might have to remove from it in a year. What was the man in such an eventuality to do with his stock, which he would suppose might amount in value to about £2,000? Was it likely that he would get into another farm just at once? He might not, and he might in consequence be exposed to heavy loss. This was the great objection to the no-lease or short-lease system. A good deal had been said about game. It was generally admitted that it was wrong for a man to be bound to protect game to any extent the proprietor liked. He had never himself been hurt by game. He had received damages for injury by rabbits; but a man might be much hurt by rabbits—as, for instance, where his land was almost all in pasture—and not be able to show it. Rabbits were a great evil, and no man should subscribe a lease binding him to preserve them.

Mr. CUNNINGHAME (Shields) said he had heard it said that the subject they were met here to-day to discuss was one which they should not meddle with. On asking the question, Why so? the answer given was, Because it might offend the landlords. Now, he had no patience with those people who were always going about tormenting themselves and others with the silly idea, that if they thought or spoke differently from those who were above them in station, then those people were sure to be offended. He was quite of a different opinion and had no such fear. Of course, as in other classes, so amongst landlords, there were doubtless a few who acted imperiously towards their tenants, allowed them as few opinions of their own as possible, made tools of them in political partisanship, and even prevented them becoming members of such clubs as this. Of such landlords he did not mean to speak further than just to say this, that it was wonderful, nay, passing strange, that they seemed to have little or no difficulty in getting willing slaves to farm their lands, and otherwise back and bow at their bidding. But he was persuaded better things of the bulk of their landed proprietors, and had yet to learn that they did not respect the man who thought, and spoke, and acted, like a man, in an upright, honourable, and conscientious manner, although he might differ from them on many subjects. To make good his assertion he would give a case in point, the truth of which he would vouch for. He knew two farmers who were neighbours (but under different landlords), and they were what was termed Liberals in politics. It so happened at an election time that a proprietor in their neighbourhood was using his influence for the return of the Conservative candidate, and called on both these men to try to induce them to support his Tory friend, and was successful in winning over one of them. Well, it so happened shortly thereafter, that this proprietor and his brother, at their mother's death, required some one to make a valuation of some farm implements and other moveables on the estate, and they agreed to ask one of those two farmers; and which did they fix upon? The one who remained firm and true to his convictions, and voted against them. When his neighbour heard of this, so mortified was he, that he called and expressed his indignation thus: "Well, this beats all: I voted against my mind to please them, and yet they came and took you to do this valuation business." That clearly showed that those people could and did appreciate an upright character, and he concluded therefrom that instead of landlords being displeased at their discussing such questions, they would rather be delighted, if they could in doing so show from their practical knowledge and experience that there were reforms and improvements which, when effected, would prove not only highly beneficial to both their interests, but also to those of the whole community. He would take leave here to say that they had grievances which he verily believed many landlords were in a great measure entirely ignorant of, and why? Just because they had never been brought under their notice. He thought he was justified in saying so, from the statement made by Mr. Baird in his speech at Ayr, viz., that he had only lately been made aware that farmers were so restricted that they could not use their skill or discriminating knowledge as to putting in what they might consider the most suitable crop for a certain kind of soil, but were obliged to act in a kind of mechanical way, and put in such crops as were prescribed in the lease, although they might be the most incongruous. It would be vain in them, then, to expect to be relieved of these grievances, if the parties who alone could grant the needed deliverance were not made acquainted with them.

Now, he supposed this was one of the purposes for which this club was instituted, and he rejoiced at the opportunity of making known their wants thus plainly and publicly, where they might be known and read by all men. With regard to this lease question, they should try to show that the alterations asked for would really be for the advantage of both landlord and tenant (for they could seldom separate the two interests); and he thought there would be little difficulty in doing that. In the first place they were all agreed that the lease system was a good one, for the high position which Scotch agriculturists had attained to in their profession was attributable in a very great measure to their having leases of considerable length. What they wanted now was to improve on that good system and make it better. There was no such thing as standing still in this world; they must either be in a progressive or retrogressive state. Well, it was his humble opinion that Scotch agriculture was at its height under the present system of management; and if it was to progress further, then it must be freed, and that speedily, of all fetters and unnecessary prohibitions, while those engaged in its advancement must have full and free scope afforded them for bringing to bear all the energy and skill which they might have acquired in their theoretical, practical, and scientific researches. And looking abroad into other countries, and seeing the ever and anon increasing competition they had to encounter, and bearing also in mind the ever-increasing expenditure on the working of their farms, they needed helps, not hindrances, to enable them to keep their ground, not to speak of making progress at all. If landlords expected to continue to get the same high rents paid, then they must themselves come boldly to the rescue, and sweep away those feudal enactments in the statute book and those stringent clauses in leases which encumbered and fettered the enterprise of tenants, and prevented them from making a practical application of useful discoveries in the science of agriculture. To prescribe an invariable mode of cropping was just to render the agricultural practices of the farm stationary, to stereotype all the usages and actions of a bygone period, and to prevent the tenant from applying the powers of his mind and body in devising another and better mode of cultivation. If they were still to travel on in the van of agricultural progress, then they must have more elbow-room to enable them to dig deeper, manure heavier, sow more generously, and thus reap more bountifully. With regard to the length of leases, he thought they should not be less than twenty years, for in general to make a farm pay it required a large extra outlay to be made in the first half of the lease in the shape of drainage, cleaning, and extra manuring, so that it took the remaining

ten years to make up the requisite remuneration for former outlays, if the farm was to be kept up in good condition. A lease should be brief, and its clauses few and simple. Of course the landlord should be protected against the deterioration of the subject let; but he thought he would find the best protection in the choice of a good tenant, and giving him full and free action to manage the land as he thought best, without prescribing any fixed rotation of cropping more than this, that there should never be more than a certain breadth of the farm under white crop in any one year—it might be two-thirds, two-fifths, or one-half, as the case might be; and that two white crops should not follow each other, where the land was suitable for green-cropping. He would approve of the farm being brought into a certain rotation during the last four years of the lease. He might here state in passing how a certain unnecessary restriction affected himself. He was prohibited from growing beans as a green crop, and it so happened that the harder and colder portions of the different breaks were unsuitable for the growth of potatoes, so that they had always to be cropped with turnip; and having been turniped every fifth year for a considerable period, the land had become tired for want of change, and the crop always more or less damaged from finger-and-toe and other diseases. Now, he would just ask the question whether the land would be in better order for the following crop after a full crop of beans, well cleaned during their growth and again after being harvested, than after a meagre crop of diseased turnips? He was aware that some farmers believed in reducing the condition of their farms towards the end of their leases, but it was a grand mistake to suppose that a tenant could with profit to himself injure the land. He believed it would be a very nice question to say when one could hold off treating land well without hurting himself; and where one willfully deteriorated a subject, he should be made to pay sweetly for it. On the other hand, where a man improved land, and was obliged to leave it, he should be remunerated for such, as well as unexhausted manures, &c. He thought it would be better for both parties if arrangements were made at least two years before the expiry of the lease whether the tenant was to remain or go; and he agreed with those parties who had already referred to lawyer factors, who had no knowledge of practical agriculture, that they were obstructionists to the promotion of the welfare and best interests of either landlord or tenant.

The CHAIRMAN, in closing the discussion, said he ventured to hope that some little good would come out of it. He thought they had conducted the discussion in such a spirit as to convince the landlords that they had their interest as much at heart as their own.

## OUR TOWNS AND SEWAGE EXPERIMENTALISM.

Not a few of our large manufacturing and commercial towns are sadly bewildered in golden dreams about their sewage. Although day-dreams ought to have nothing to do with the practice of agriculture, yet amateur experimentalists in almost every province of the kingdom are doing their best to make an exception to this desirable rule; and perhaps there is no other branch of the parent art that holds out a more favourable opportunity for day-dreams than sewage farming. To be before the public appears the ruling ambition of the age in every branch of art; and, however unlike the others in many respects the parent one, it bids fair to be in fashion. It is no wonder, therefore, if minds of a thoroughly practical turn feel disposed to think twice before making a jump in the dark. The plain truth of the matter is, that sewage farming is at a discount in the market, the supply being greater than the demand.

The question why the landward demand for town sewage is not greater requires a practical answer. In the immediate neighbourhood of almost all our large towns there are hundreds, and even thousands, of hungry acres, actually starving for the want of food; and yet nine out of every ten farmers in possession of such land will tell you, many of them with the authority of a lifetime's experience, "It won't pay," "It ain't the sort of manure that my lands require," and so on. This and the other successful experiment, let it be performed by an amateur professor mostly engaged in some other branch

of industry, or by a practical farmer who has been in harness from his teens, and whose whole time is devoted, day after day and week after week, in the enterprise, go for nothing in their estimation, physical differences being so many and great as to silence all opposition to the contrary.

However vaguely and imperfectly farmers may express their convictions in such instances, there cannot be a doubt that such convictions are, generally speaking, based upon fact, and that the force of fact will, as it has ever done, carry before it all the argument which science can oppose. Indeed, Science, with all her powers, may just as well think to change the wind by force of speech, as to overthrow the convictions of practical farmers, so long as those convictions are based upon fact—such as diversity of soil, inclination, exposure, and the like. Well-performed experiments all successful and practical farmers can appreciate at their true value. But that appreciation is the very groundwork of their faith—in their own experience, and the capabilities of their own farms—the corner-stone, as it were, of their conviction that, because sewage suits this or that soil, it will not suit their farms, owing to physical and other differences. That artificial management may so change their farms as to adapt them for the successful application of sewage may be granted; but fireside arguments of this kind are, practically speaking, worth something less than nothing; for, until such changes are actually made,

their practical value cannot be estimated by experiment, *i.e.*, they do not reach the convictions of those who base their judgment upon observation or what they see.

In perhaps ninety-nine cases out of every hundred an experiment upon a farm is but a fireside theorem when taken to another farm; and there is little doubt towns will find such fireside theorems to be the greatest stumbling blocks to the profitable disposal of their sewage to successful practical farmers. It is not to be inferred from this that we are estimating fireside farming at one farthing below its real value, or that, indirectly, we aim at shunting it altogether off the line. Quite the contrary; for farmers themselves could not get through the long winter evenings without "much ado about nothing," if we may so express ourselves. It is not fireside farming that does the harm, but the substitution of fireside farming for experimental or practical farming; for all such substitution is a species of quackery in disguise; and therefore our large towns cannot be too much on their guard in listening to the silver tongue of fireside theory.

The really practical question is, how to make the most of successful experiment here and there, without being imposed upon? All successful experiments elicit certain important truths which practical men can fully appreciate. How far this or that town can profit by such truths, in the utilization of its sewage, is another and a very different question; for it would be a hopeless task to attempt the enumeration of such truths, or even to give a tithe of them. No doubt, gab-gifted people may talk fluently of porous soils, gravelly and sandy soils, clays, loams, and so forth, lying at certain inclinations to this or the other point of the compass; but unless they are or have been brought under the eye of the practical farmer, all such talk, to him, is only so much fireside theory. In other words, the question is a comparative one between two practices distinct from each other, two practices which cannot be reduced to a common equality, so that each must be its own rule. In short, apart from the manual question as to the fertilising value of the sewage, and the commercial question as to the value of the produce of the land, each town must be guided by its own peculiar soil, inclination, experience, and so forth, in the application of the truths in question. In the form of an interrogatory: If this or that town or sewage-farm produce certain results, what can another town or farm produce?

The above interrogatory form is perhaps the most instructive way of putting the question, as it illustrates very forcibly the truth of the old, time-tried maxim, "Mind your own affairs if you wish to profit by them." Ap-

ply your own sewage to your own land if you wish to realize its true agricultural value, and let other towns and experimentalists do the same. Profit by any practical lesson you receive, but in making a new spoon take care you do not spoil an old horn. However different farming may be from the various occupations which engage towns-people, few of them can misapprehend the weight of such arguments; for the produce of one farm under a certain course of sewage-management may furnish some idea of what another farm may produce, but the amount of produce yielded by the former ought never in any estimate to be mistaken for that of the latter, and in every case towns should never count their chickens before they are hatched, or disappointments will be experienced. No doubt in carrying out into practice these time-tried maxims an apprentice fee has to be paid. There is no way yet discovered for avoiding this; but this is just the point where one town ought to profit by the experience of those a-head in the utilization of their sewage, if the necessary caution and circumspection be observed, relative to the truths which successful experiment teach, as already noticed in the preceding paragraph. All towns cannot hope to profit equally from any one successful experiment or practice, owing to diversity of physical and other circumstances, so that different experiments and practices have to be investigated with the view of profiting by what each may teach; and the instruction thus afforded may as often be of a negative character as to what should be avoided, as of a positive character, relative to what may be adopted with promise. Practical farmers are perhaps more familiar with the negative rule than the positive one, and towns will do well to profit by their experience in this respect.

The sewage proposition of each individual town in the kingdom requires thus to be seen and examined in its own light, so that the utilization of the whole of the town sewage in the kingdom forms a comprehensive subject. And as it is the individual cases that constitute the whole, the prudent, and, indeed, the only practical and successful courses is to discuss the former, prior to entering upon the latter. Those who reverse this order of investigation put the cart before the horses. Towns are sadly overlooking the force of this argument. What has the metropolis to do with the farming of the Edinburgh sewage? or the town of Montrose to do with the farming of the sewage of Croydon? and so on for other towns which we could mention, each being engaged in discussing the farming of the other's sewage, instead of farming its own. Until this adverse rule is set aside, and the opposite one enforced, little progress can be expected in the solution of the general question. X. Y. Z.

## ARTIFICIAL MANURES—CHEAP AND BAD.

At the last meeting of the North Durham Chamber of Agriculture, Mr. GILLART, of Wynyard Park, drew attention to a very important matter, in order that it might hereafter be fully discussed. There were two ways of dealing with the question. One was by bringing prominently before the minds of farmers the great practical advantages which the application of chemistry to the cultivation of the soil was calculated to bring about. This was to be achieved by employing practical chemists to give lectures in the towns and villages of the district in which the chamber was established. This, however, would be a costly mode of introducing the subject, and one which at present the chamber would scarcely be justified in incurring. Another and very practical mode of giving to farmers the benefits of chemical science would be to institute arrangements for the analysis of artificial manures. The chemical constituents of artificial manures were not sufficiently understood by those who purchased them, and much loss and disappointment frequently arose from the want of this knowledge. Very often farmers were tempted to buy cheap or rather low-priced manures, and the crops not turning out what they anticipated, they became discouraged, and perhaps in future were led to depreciate and under-value all artificial manures. This was a double mistake; it was an error in the first instance to purchase without a knowledge of its chemical constituents a manure apparently cheap, but really dear, and it was wrong to suppose that all artificial manures were equally

unreliable. There were in the market some excellent artificial manures, and there were others which were downright impositions. Unfortunately the least informed and the poorest farmers were generally the victims of those who manufactured and sold these worthless preparations, and it was the more humble class of agriculturists that he desired the North Durham Chamber of Agriculture should endeavour to devise means for protecting from fraud. The better class of farmers, from their more extended knowledge and information, were able to take care of themselves; but the small farmers were those who chiefly suffered by spurious preparations such as those to which he referred. He could mention numerous cases where men had been imposed upon, but he would adduce a single instance by way of illustration. A person wanted a respectable dealer in guano to supply him with the best Peruvian for £13 10s. He stated that he could not do so, that the article could not be bought in the market under £13, and if he was not satisfied he could try somebody else. The farmer purchased a lower priced article, but he was very much dissatisfied with the results, and on a sample of his purchase being afterwards analyzed, it was found not to be genuine, and was not worth more than £8. In fact, he had been imposed upon by a spurious article; he lost his money in the first instance by paying a high price for a poor article, and in the second by the inferiority of his crop. Discouragements such as these, and want of

knowledge as to the causes from whence the failures proceeded, naturally excited a prejudice against artificial manures, and in the end there was a very serious check on the progress of agriculture. In a poor county like Durham, where the land was not naturally very productive, artificial manures were particularly requisite, and it was of the more importance therefore that they should have confidence in what they purchased. Many people, unfortunately, from want of due thought, bought from parties of no standing whatever; and then, getting disappointed, they became less and less enterprising, and poor farms got poorer still. It was of immense benefit to know what were the right ingredients to apply to land. The dissemination of knowledge on the principles of chemistry as applicable to agriculture could perhaps be the most successfully effected by lectures, but there could be no question that analyses such as he suggested would be of great practical utility. Perhaps they could not go so far at present as to undertake the analysis of soils, but he thought they might for a very moderate outlay undertake to employ an analytical chemist to test the fertilising properties of artificial manures. In the present day, in farming, as in all other businesses, competition was very strong, and farmers could ill afford to waste their money in the purchase of stuff which was of no value. He did not wish to hurry them to any decision on the subject that day, but he thought it a very proper subject for the consideration of a chamber of agriculture. Should the Chamber, after the subject had been fully considered, appoint a chemist to conduct analyses such as he referred to, no doubt it would be of great service to farmers and to agriculture in general.

Mr. T. WEARMOUTH said he hardly thought the Chamber should be at the cost of protecting those who were so foolish as to expend their money in these low-priced manures. If they went to a respectable agent they would get an analysis, and a guarantee that the manure supplied should be like the sample. He was surprised that men should be so foolish as to purchase the low-priced blood manures, and the mere sweepings and dirt which were sold for artificial manures now-a-days. If they went to a good man for guano, and to another for bones, they would get a good article without an analysis. Cockle-shells and oyster-shells were very largely mixed with some of these manures, and he had for years thrown away £20 a year in purchasing such rubbish for genuine manure (laughter). He had given up the oyster-shells now, for he found that guano and half-inch bones were far more profitable (laughter). A lot of the artificial manure now sold was dirty rubbish, against which common-sense should guard them. They wanted no protection against such stuff as that.

Mr. HOLMES: It appears you required it when you bought oyster-shells (laughter).

Mr. GILLART said it was against the practices of men who had not established reputations as manure-dealers that it was so desirable to guard the poor man. By plausible pretences they imposed upon poor farmers who had no means of testing the value of the articles in which they dealt. The object of an association like the North Durham Chamber of Agriculture should be to encourage dealers who sold the best manures, and those who sold the worst they should endeavour to wipe out. If farmers had the means of testing the qualities of manures by the aid of an experienced chemist, dishonest dealers would be deterred from practices so dishonourable as those referred to.

The CHAIRMAN said the subject introduced by Mr. Gillart was one of very considerable importance. The great difficulty was to get a certain class of farmers to understand the difference between low-priced and cheap articles. They were apt to think more about saving, as they thought, a few shillings, than they were about buying a first-rate article, the purity of which was known. They don't think that the value of a manure consists in the ingredients of it, and they will thus buy a low-priced rather than a superior article. The best way of course was to have a fair sample from the bulk, and to have it analyzed before it was tried. A great many parties, however, did not think of purchasing their manure before they wanted to use it, and there was not then time to analyze it. The only protection against fraud in such cases was to deal with large and honourable firms, whose interest it was to supply the best article they possibly could. Their profits depended upon showing that their manure was better than their neighbours'. It would be a good plan to get farmers to retain samples of their manures, so that actions could be brought against parties

who sold manures which were comparatively worthless. In Scotland penalties had been recovered from parties who had sold useless compounds for manures.

Mr. WEARMOUTH said he thought the evil would cure itself in time.

The CHAIRMAN said in the case he referred to, the man lost his whole crop of turnips, and he recovered substantial damages.

Mr. WEARMOUTH said the price of Peruvian guano was so well known, that anybody purchasing an article for less than that sum must know it was not pure.

Mr. JOHN FURNEIS said they all knew the price of good Peruvian guano, but there were other artificial manures manufactured which in some measure came into competition with it, and encouragement of those who made good manures of this description might bring down the price of guano. Their object should be not only to put down those who sold an inferior article, but to encourage those who produced a good one.

Mr. WATSON said if the benefits of analysis, such as had been recommended, were confined to the members of their association he thought Mr. Gillart's project could be carried out. The idea was a very practical one, and much good might be effected. An instance came before him not long ago, in the way of business, where a farmer near Lancaster bought some guano or artificial manure, which was represented to be of very excellent quality. He tried it, and it turned out to be almost worthless. Fortunately, he retained a sample from the bulk, and he (Mr. Watson), on being consulted on the subject, sent the sample to an eminent chemist in Newcastle for analysis. That analysis he would bring with him to the next meeting of the Chamber. He might state, however, that the analysis fully confirmed the farmer's suspicions that he had been imposed upon, inasmuch as he had received for £10 10s. a ton an article the outside value of which was £3 10s. a ton. If that Chamber could protect its members from such impositions, he was sure that it would confer a very great practical benefit; and he thought Mr. Gillart was entitled to their thanks for having brought such a very proper subject before the meeting.

Mr. WEARMOUTH said he quite agreed with Mr. Furneis that it would be very desirable to encourage the manufacturers of good artificial manures; but the idea of buying pure guano at £10 10s. a ton was ridiculous.

Mr. WATSON said every man should retain a sample of his manure.

The CHAIRMAN asked Mr. Watson what damages were recovered in the case he had referred to.

Mr. WATSON said an action was brought against his client to recover the value of the manure. A small sum was paid into court, and the manure dealer recovered a little more than that, but nothing like the sum charged for the guano.

The CHAIRMAN said Mr. Watson's client lost his crop, which was of a very great importance. Had he brought an action to recover damages, he believed, from the case which had been decided in Scotland, that he would have been successful.

Mr. WATSON said the question of damages did not arise.

The CHAIRMAN said that was made the material question in Scotland, and penalties were recovered.

Mr. HEWITSON said he believed the Highland Society had for a number of years undertaken to analyze samples of manure.

The CHAIRMAN said he believed they contracted for these things.

Mr. FURNEIS said the Royal Society had a sliding scale of charges for analyses, charging so much for analyzing guano, and so much for analyzing soil.

The CHAIRMAN said such an analysis as they required would not be a very costly one. They wanted to know the quantity of fertilizing properties the guano contained. They did not wish to learn with precise accuracy the whole of the ingredients.

Mr. WHARHAM said he had had some conversation with Mr. George Shaw on this very subject, and Mr. Shaw had communicated with an eminent chemist in Newcastle, and had procured from him a scale of charges for quantitative and qualitative analyses. He was sorry Mr. Shaw was not present, as

he would have been able to give the chamber some useful information.

Mr. GILLART said it was not a question which he wished to hurry on at all: even the ventilation of such a subject might be useful.

The CHAIRMAN said anything they might do in the way suggested should be confined to the members of the chamber, and there would thus be an additional inducement to farmers to band themselves together in an association of that character.

Mr. WATSON said the funds of the Chamber would not

permit them to pay the cost of analyzing manures purchased by those who were not members of the Chamber.

Mr. HOLMES said he and Mr. George Crofton once had a joint investment in an "Economical" manure, and it was so economical that neither of them ever got a turnip (laughter).
